COUGH. See MEDICINE.

COULAM, or COVALAM, the *Colis* or *Colias* of the ancients, is a small town of Hindostan, situated on the western side of Cape Comari. The ruins of the fortress, which formerly belonged to the Imperial East India Company at Ostend, are now the retreat of a multitude of snakes. A great number of very beautiful shells are cast on shore here by the sea. The principal productions of the place are millet and salt, the latter of which may be collected by the Christians as well as by the Pagans, the former of whom are very few in number, while the town abounds with Mahometans.

On the sea-coast between Coulam and Sadras, are situated seven temples, which are reckoned masterpieces of ancient Indian architecture, being cut out of the hardest rock, in a mountain covered with trees. The entrance fronts the sea, and is excavated from the solid rock, which forms part of the summit of the mountain. It is 20 Roman palms broad, and 15 high, and has its sides covered with the figures of various sacred animals as large as life, such as the elephant of Rama and Gannesha, the tortoise of Vishnu, the ape of Rama, the wild sow into which Vishnu metamorphosed himself, the cow of the goddess Parvadi and Lakshmi, the fish as the symbol of water, the snake as the symbol of life and death, and various other animals. At the end of this passage there is a small round place in the same rock, where there is seen on the left a few stone steps, and on the right two passages, also cut out of the rock, each of which were about seven palms broad and twelve high. These steps and passages conducted to the temple, which consisted of extensive apartments, or caves, with vaulted roofs, and separated from one another by walls hewn from the solid rock. They are all supported by pillars cut out of the rock, the largest apartments being below, and the smallest above. A very great number of colossal statues, hewn out of stone masses, are placed around the walls. Among these are the gods Brahma, Vishnu, Sheva, Rama, Krishna, Devendra, Kartiguna, and Gannesha, and the goddesses Parvadi, Sarasvadi, and Lakshmi, and the nine different forms into which Vishnu had transformed himself while on earth. Some idea of these temples may be formed from inspecting Plate CLI. of Civil Architecture. A minute account of the sculptures and ruins, of which the above is a very general description, will be found in the first volume of the *Asiatic Researches*, by William Chambers, Esq. See also Bartolomeo's *Voyage to the East Indies*. (*j*)

COULOMB, Charles Augustus, a celebrated mechanical philosopher, was born at Angouleme on the 14th of June, 1736, and was descended from a family which had been distinguished in the magistracy of Montpellier. Having been taken to Paris at an early age, he acquired a decided taste for the mathematical sciences; and with the view of making his knowledge subservient to his promotion, he entered into the corps of military engineers. About this time he went to Martinique, where he was employed by government in several important works; but the insalubrity of the climate, which had already proved fatal to all his companions, compelled him to seek for health in his native country, to which he returned, after an absence of nine years. The first memoir which he laid before the academy was on a subject connected with his profession, and obtained for him the title of a corresponding member. It was published in a separate work, entitled, " *Re sur les moyens d'executer sous l'eau toutes sortes de travaux hydrauliques sans employer aucun epuisement*," and was written for the prize proposed by the academy of Rouen in 1778. A second edition of it was published at Paris, in 1797. In the year 1779, he divided with M. Van Swinden, the learned author of the *Positiones Physicæ*, the prize for the best construction of the magnetic needle, and in the year 1781, he carried off the prize proposed by the academy on the theory of simple machines.

This valuable memoir, which was published in the *Memoires des Savans Etrangers*, tom. x. p. 163. contains a series of admirable experiments on friction, and on the stiffness of ropes. The subject of friction, which had been treated very imperfectly by Amontons, Bullfinger, and Euler, was here investigated with a degree of ability and success which widely extended the reputation of Coulomb. By using ponderous weights, and by conducting all his experiments on a very large scale, he has obtained results equally new and interesting. One of the principal results which he obtained relates to the effect of time in modifying the friction of one body upon another. The friction sometimes reached its maximum after the rubbing surfaces had been only one minute in contact, and in other cases the maximum effect was not produced till they had been in contact for five or six days. When a body weighing 1650 pounds was laid upon its corresponding surface, it was put in motion by a weight of 64 pounds; but when the contact was continued for three seconds, the force required to move it was 160 pounds; and when the contact was continued for six days, it could with difficulty be moved by a force of 622 pounds. These experiments were made at Rochefort, where M. Coulomb then resided; and from the naval arsenals which were under the charge of M. La Touche-Treville, he obtained every assistance that could facilitate his researches.

In consequence of the competition for the prize on the subject of the magnetic needle, the attention of our author was turned to the subject which has been the principal foundation of his fame. One of his antagonists having pointed out a method of removing the effect of torsion, or the resistance which is opposed to the magnetic force by the stiffness of the suspending wire, Coulomb applied himself to investigate the effects of torsion, and invented a machine for measuring it with precision. These researches are contained in two memoirs which were published in the Memoirs of the Academy, under the title of *Recherches Theoriques et experimentales sur la force de Torsion, et sur l'elasticité des fils de Metal.** In these experiments Coulomb employed a very simple apparatus. A metallic wire suspended vertically, was firmly fixed at its upper end, and its lower end was fixed into a cylinder, also vertical, and having a horizontal index. By turning the cylinder about its axis the wire is twisted, and when let go, it endeavours, in virtue of its elasticity, to recover its form. The index will therefore oscillate round the axis of the cylinder. The force which produces these oscillations is called the *force of torsion*, and the angle measured by the arch which the index describes, the *angle of torsion*. After having deduced the formulæ for the oscillatory motion of the cylinder, on the supposition that the reaction of the force of torsion is proportional, or nearly so, to the angle of torsion, Coulomb proceeds to determine by means of these formulæ, the laws of the force of torsion relative to the length, the thickness, and the nature of the wires which were used; and from a great number of experiments, he obtained the following results:

1. For all metallic wires, when the angles of torsion are not very great, the force of torsion is sensibly proportional to the angle of torsion.

2. The duration of the oscillations is as the square roots of the weights of the oscillating cylinders.

3. The times of the same number of oscillations are as the square roots of the lengths of the wires.

4. The momentum of the force of torsion varies as the fourth power of the diameters of the wires; and,

5. In metallic wires, the momentum of torsion is directly in the compound ratio of the angle of torsion, and the fourth power of their diameter, and inversely as the length of the wire.

In the year 1781, Coulomb arrived in Paris, and was immediately elected a member of the Academy. His attention was now directed to the subject of electricity and magnetism; and the rest of his life was employed in this important investigation. By a series of delicate experiments, he demonstrated that the attraction of magnetism is inversely as the square of the distance. He improved the dipping needle and the common magnetic needle, and with the aid of theory, he gave a new degree of perfection to the method of making artificial magnets. The most important, however, of all his results, relates to the effects produced upon the magnetic action

* See *Mem. Acad. Par.* 1784. p. 229.

Coulomb. by difference of temperature. He found that it diminishes as the temperature is increased; and with the assistance of a theorem by M. Laplace, he found that a magnetic needle must acquire a temperature of 700° of the centigrade scale, before it is entirely deprived of its magnetism. It had long been believed that iron was the only body that possessed the magnetic virtue, but Coulomb found unequivocal marks of attraction in almost all bodies that he tried; and hence he concluded, that magnetism, like electricity, was extended through all nature. This discovery was the last which he made, and his latest moments were employed in verifying it. Several curious experiments have been found among his manuscripts, from which it seems to follow, that if the magnetical attractions, which he discovered in different bodies, were owing to the presence of iron, the quantity of this metal must be so considerable, that it could not have escaped the notice of chemists.

The attention of Coulomb having been particularly directed to the subject of wind-mills, he published the results of his researches in the Memoirs of the Academy for 1781, under the title of *Observations Theoriques et Experimentales sur l'effet de Moulins a vent, et sur le figure de leurs ailes.* These experiments were made upon more than fifty wind-mills in the neighbourhood of Lisle. He found that almost all of them performed nearly the same quantity of work when the wind moved with the velocity of 18 or 20 feet per second, and from this he justly concluded, that the parts of these machines must have been so adjusted as to produce nearly a maximum effect.

In the latter part of his life, Coulomb was appointed commissary to the king in Bretagne, and was sent by the minister of the Marine to examine the canals and public works in that province. On this occasion, it required all the energy of his character to stop the ruinous projects which had been on the eve of execution; and the province, out of gratitude for his services, rewarded him with a very considerable present.

At the commencement of the revolution, Coulomb resigned almost all his offices, and particularly the general superintendance of the fountains of France, which had been hereditary in his family, and which he had hoped to transmit to his children. He employed himself in collecting the wrecks of his fortune; and expected to find, in the continuance of his scientific labours, and in his correspondence with the Academy, that happiness of which external circumstances could not deprive him. The Academy, however, was suppressed, and his situation as member of the Commission of Weights and Measures was taken from him. He was soon after compelled to leave Paris, by the edict which expelled all the nobles; and he retired with his friend the Chevalier Borda to a small estate which he possessed near Blois. In this retreat, he pursued, in the bosom of his family, those studies which had in better times occupied his mind. His attention was accidentally directed to the subject of vegetation, and he made some experiments on the motion of the sap, of which he has given a short account in a paper published in the *Memoirs of the National Institute,* tom. ii. p. 246, under the title of *Experiences relatives a la circulation de la seve dans les arbres.* The result of these experiments, which is however proposed merely as a conjecture, is, that the circulation of the sap in vegetables is carried on by the parts adjoining to the central canal of the tree, and by the infinity of medullary horizontal radii, which form a communication with the axis of the plant. Coulomb.

In the year 1798, Coulomb read to the national Institute a long and valuable paper, entitled *Resultat de plusieurs experiences destinées à determiner la quantite d'action que les hommes peuvent fournir par leur travail journalier, suivant les differentes manieres dont ils emploient leurs forces.* In this elaborate paper, which consists of thirty sections, the object of the author is to determine how much loads of different magnitudes may diminish the quantity of action which a man can furnish in a day; and the experiments which were employed for this purpose, were made upon the most natural and ordinary motions of men, such as walking horizontally, or mounting a ladder. He found, that the load which a man ascending stairs should carry, in order to produce the greatest useful effect, is 173.8 pounds avoirdupois, on the supposition, that he is to continue the exertion during a whole day. In this case, the quantity of action which the labourer exerts is 183.66 pounds avoirdupois, raised through 3282 feet. Coulomb then proceeds to compare the total quantity of action which a man can furnish when ascending steps, with that which he exerts in driving a winch, in digging the ground, in pulling a rope horizontally, and in walking on a level road; and the general results of these comparisons, give quantities of action much less considerable than those which had been employed by all preceding authors in their calculations of machines. Coulomb also found, that the mean quantity of action depended greatly on the food, as well as on the climate; and that in warm climates, such as Martinique, where the labourer is almost always inundated with perspiration, the quantity of action furnished by one man is scarcely one-half of that which is furnished in France.

The subject of magnetism continued to occupy the thoughts of Coulomb, and he produced a very valuable paper in 1800, which was published in the Memoirs of the Institute, tom. iii. under the title of *Determination Theorique et Experimentale des Forces qui ramenent differents aiguilles aimantées a saturation, a leur meridien magnetique.*

In the same volume of the Memoirs of the Institute, he published one of the most curious of all his papers on the cohesion of fluids. It is entitled, *Experiences destinées a determiner la coherence des fluides et les lois de leur resistance dans les mouvements tres lents.* In these experiments, Coulomb employed the principle of torsion, for determining the cohesion of fluids, and the laws of their resistance, in very slow motions. Newton, D. Bernoulli, and Gravesende, represent the resistance which a fluid at rest opposes to a body in motion, by a formula of two terms, one of which is as the square of the velocity, and the other constant; but Coulomb has shewn, by unquestionable experiments, that the resistance is represented by two terms, one of which is proportional to the simple velocity, and the other to its square, and that, if any constant quantity exists, it is extremely small. He proposed, in a subsequent memoir, to ascertain numerically, the part of the resistance which is proportional to the single velocity, and to determine the resistance of globes, with convex, concave, and plain surfaces; but this second memoir was never published.

From his state of exile Coulomb was afterwards recalled to Paris, to resume his labours relative to the new measures; but he did not remain long in that metropolis. He was pressed to rejoin his wife and family, and to take charge of the small property which was their only resource; and he did not again return to Paris till the establishment of the National Institute, of which he was elected a member. His health, too, which had long been in a declining state, required the assistance of art; and he suffered extremely from the effects of a nervous temperament, which produced a vivacity of character, and an impatience of temper, which he found it very troublesome to restrain.

He was now appointed one of the inspectors general of studies; an office which he accepted after much hesitation, but which he filled with great credit and usefulness. The general debility with which he was afflicted, was now greatly increased by a slow fever, which threatened his existence, and which reduced him so much, that he was unable to take any nourishment. The skill of his medical friends was employed in vain, either in assuaging his distress, or in restoring his health; and he died on the 23d August 1806, at the age of 70, leaving behind him two sons, with no other inheritance but that which was derived from the virtues and the talents of their father.

The public as well as the private character of Coulomb were universally admired. In the various relations of domestic life, he conducted himself with the utmost prudence and affection. Severe to himself, and indulgent to others, he united the most easy manners with a gravity of character which inspired respect. He was unassuming, generous, and disinterested, without possessing any of the failings by which these virtues are frequently obscured.

Beside the works which we have had occasion to mention, Coulomb wrote an able dissertation on the force of steam, which was read to the academy in 1775, and published in their memoirs; and he intended, at the earnest request of his scientific friends, to collect all his memoirs into a separate volume. He had proceeded so far in this work, as to transmit to his bookseller a note, containing the order in which he wished them to be printed.

The English reader will find an account of several of Coulomb's experiments on windmills, and an abstract of his experiments on friction, in Ferguson's *Lectures*, vol. ii. Appendix; and in our articles Electricity, Hydrodynamics, Magnetism, and Mechanics, we shall have frequent occasion to follow him in his career of discovery. (*w*)

COUNCIL. See Ecclesiastical History.

COUPANG, a town in the island of Timor, is the capital of what was formerly the Dutch part of the island, and is situated on the south-west end of the island, at the bottom of a deep bay, which affords excellent anchorage for shipping. There is a fort here, called Concordia, where all the Europeans reside. It is close to the water's edge, and was built by the Dutch in 1613, when they expelled the Portuguese from that part of the island. The Chinese and the natives reside in a village without the fort. There is a small fresh water river to the east of the fort, which is navigable for a long boat at high water. The governor of Coupang has authority over Rotti, Savu, and some of the other adjacent islands. The Dutch districts in Timor were lately taken possession of by the English. The only trade carried on at Coupang is with Batavia, from which the Europeans obtain necessary articles, and a small quantity of piece goods, iron, steel, opium, &c. The exports to Batavia, which are given in exchange for these commodities, are slaves, gold dust, and wax. China weights are in common use at Coupang, and Dutch money passes here as at Batavia. East Long. 124° 5′, South Lat. 10° 9′. (*w*)

COURLAND, the Duchy of, in the ci-devant kingdom of Poland, is bounded on the north by the gulf of Riga, on the west by the Baltic sea, on the east by Lithuania, properly so called, and on the south by Samogitia. It stretches in length about 250 miles, and its average breadth may be estimated at about 60 miles. It is in breadth, indeed, very irregular, extending in some places 80 miles, in others scarce 30, and towards the east terminating in a point. It is situated in E. long. between 21° and 26°, and between 56° 30′ and 57° 30′ N. lat. constituting now a province of Russia, and one of its great divisions subject to a distinct jurisdiction.

The duchy of Courland is divided into three parts, viz. Courland properly so called, Semigallia, and the district of Pilten. The latter of these has its own particular constitution. Courland and Semigallia are divided into great governments, and these again into circles or districts called parishes.

The duchy of Courland swells into gentle hills. The soil is fertile, producing corn, hemp, and flax, in abundance. The country for the most part is open, but in some places it is clothed with forests of pine and fir. There occur also occasionally groves of fine oak, and there is no want of shrubs and underwood. Courland is noted for its breed of horses: black cattle also are reared in plenty; and the country is frequented by a great variety of wild animals, such as deer, bears, lynxes, wolves, martens, elks, and others.

Courland exports a great part of the produce of its soil, its corn, hemp, and flax. Besides these there are various other productions, which, either in a natural or prepared estate, may partly be disposed of abroad, such as its timber, masts for ships, potass, skins, turpentine, wax, amber, iron, copper, chalk, &c.

In return for these articles, Courland imports coffee, tea, wines, cloth, salt, and other foreign merchandise, in sufficient quantity to supply the internal consumption. The hemp seed of Courland, which is sent out of the country in great quantity, is the most esteemed of all the seed of this kind that is obtained from the north. The Dutch have been accustomed to make oil of it; and it has been usually sown throughout Flanders and France, as well as pretty generally in other parts of Europe. The Dutch alone have been in use to send not less than 25 vessels annually into Courland, on account of this trade. The situation of the duchy on the Baltic sea is very favourable for the prosecution of its commerce. The principal ports, Libau, and Windaw, have no great depth of water. The inhabitants of these two cities have, however, been in the practice of sending out many vessels to sea. Under their duke Jacob, some of those ships proceeded as far as to America, and colonies were established by this people in the island of Tobago. The two ports together employ annually from 800 to 1000 vessels, of two, three, and four hundred tons.

The most considerable towns of Courland are Windaw, Libau, Goldengen, and Mittau. The last is the capital of the duchy. There are besides many neat villages, and the scattered cottages, and gentlemen's seats, prettily situated amid clumps of trees, give to several parts of the country a very agreeable and picturesque appearance.

The chief rivers of this duchy are the Duna, or Dwina, which taking its rise in Russia, after running a long course, finally falls into the gulf of Livonia at Riga; the Windaw, which has its source in Samagitia, and joins the Baltic Sea near to the city of Windaw; and the Aa, which taking that name where the Muss and the Memel unite their streams, passes by Mittau, and discharges itself into the gulf of Livonia. These two last rivers, which are navigable, divide the country from east to west. There are besides several smaller rivers, such as the Abau, Berse, Bartau, Mussa, Anger, and some brooks and canals, by which it is intersected in every direction.

In the duchy of Courland there are mines of copper and iron. There are also quarries of stone and of chalk, and mineral springs. Its riches, in this department, are, of course, chiefly to be looked for in the more mountainous parts of the territory.

The constitution of the goverment of Courland is rather of a complicated nature. The crown of Poland, the duke, and the diet, have their respective rights, which are so much interwoven, that a somewhat accurate inspection is necessary towards ascertaining precisely the just boundaries of each of those divisions of the authority exercised in it. Courland is a male fief, dependent on and conferred by the crown of Poland. The territorial superiority of that sovereignty is settled by the *Pacta subjectionis*, or acts of vassalage, which are ratified severally by the king of Poland and the duke of Courland, at the time that the duke receives his investiture. In consequence of this territorial right, the king is empowered to invest each duke with the duchies of Courland and Semigallia, as fiefs of Poland, and to receive in return his homage, as from a vassal to his liege-lord.

When Poland is engaged in war, the duke is bound to furnish 200 horse, or 500 infantry; and the nobles 200 horse, or 30,000 dollars, in the first year of the war, provided no Polish or enemy's troops are quartered in the duchy; in each succeeding year 10,000 dollars. The money of Courland must be struck on the same standard as the coin of Poland; it is also to bear on one side the head of the king, or the arms of Poland and Lithuania: likewise the Polish money must pass current in Courland, and the Courlandish in Poland. All disputes between the duke and his subjects are to be settled by the king, who receives remonstrances from the diet of Courland against any infringement of privileges by the duke, and can order the redress of grievances. Laws tending to alter or new-model the constitution of Courland, after having been passed by the duke and diet, with a reference to the king and republic of Poland, must be finally ratified by the diet of Poland. The same diet confirms the creation of nobles, and the *indigenat recht*, or right of naturalization, recommended by the duke and diet of Courland. This is likewise the supreme court of judicature, to which any noble may appeal from the decision of the Courlandish courts of justice. In all civil causes above the value of 500 Polish florins, and in the specified criminal cases, the final decision belongs to the king and the republic of Poland. On the other hand, the Polish king binds himself to support the constitution of Courland, to maintain the duke in all his prerogatives, and the nobles and burghers in all their privileges.

In any circumstances distinct from those enumerated, and where no contradiction is involved to a feudal dependance on Poland, or no departure from the acts of subjection, the supreme authority in the duchy of Courland is vested in its own duke and diet. To the duke belongs the executive power, with the general administration of affairs; but though strictly speaking, he has the right to declare war, make peace, and contract alliances, he does not usually proceed on such occasions without consulting the diet. He has a negative on all the measures of the diet, confers the principal charges, both civil and military, has the power of pardoning criminals, and where there is no particular exception, is judge without appeal, both in civil and criminal cases. The revenues of the duke are very ample, amounting to not less than £160,000 per annum, derived from the ducal demesnes, in which are comprehended not less than a third of the duchy, from tolls and customs, manorial and feudal rights, fines, and confiscations. He is not permitted by the laws of the country to keep on foot more than 500 troops.

Of the diets, some are ordinary, others extraordinary, both being convoked by the duke, either at his own suggestion, or at the request of the nobles. With the circular letters transmitted to the different parishes for the election of the deputies, there are sent the propositions, called deliberations, which are to be laid before the diet. The deputies must be noble, and are elected by the nobles in their respective parishes. The president is chosen, after the meeting, by a majority of votes. In conjunction with the duke, the diet imposes taxes, and passes all laws and regulations, not of a fundamental kind, those themselves too being still subject to the pleasure of the Polish diet. Questions in the diets are carried or rejected by the majority; and each deputy is obliged to vote according to the instructions he has received from his constituents. At the dissolution of the diet, the deputies are bound to acquaint their constituents in person with the transactions of that assembly.

The privileges of the nobles are very great. The highest and most important officers of state are drawn from their body. They are exempted from all taxes and imposts; and any goods or merchandise imported or exported for their use pay no duty. A noble cannot be arrested for the most flagrant act but for 24 hours after the commission of the crime, unless by an order from the king and republic of Poland; he cannot be imprisoned till he is found guilty; nor can he be executed without the permission of the king and republic of Poland. The power of the nobles over the peasantry is extreme, including even what, if not altogether in appearance, is yet certainly in effect, a criminal jurisdiction over them without appeal.

By the constitution of Courland, the duke is assisted in the administration of affairs, by what is called the Supreme Council, consisting of the four high counsellors, the high steward, the chancellor, the burgrave, and the marshal. This council advises the duke as to all matters of state, guards against any infringement of the rights and privileges of the subject, and remonstrates against grievances. In conjunction also with the duke, it forms the criminal court of judicature for the nobles, to which an appeal lies from the inferior courts of justice, and which finally determines concerning all but capital offences. In cases of minority, of the absence or sickness of the duke, or on a vacancy of the ducal throne, the same four high counsellors are invested with the regency.

The prevailing religion of Courland is the Lutheran. All other religions, however, are tolerated: and by the acts of subjection already alluded to, it is provided that Roman Catholics may hold any military or civil office within the duchy, with the exception only of that of chancellor, and a few others.

The language of the native inhabitants of Courland is a dialect of the Livonian or Lettish; the same language, with little variation, that is spoken by the natives of Livonia and Esthonia, and which probably is derived from the Finnish. The nobles and gentry who are descended from German settlers, speak the German language, and it is that language which is used always in the debates of the diet.

The duchy of Courland belonged anciently to the Teutonic order, as did also Livonia. Gothard Ketler, grand master of this order, being unable to resist the Russians, who attacked and laid waste Livonia, put himself under the protection of Poland, and ceded Livonia to King Sigismund Augustus, on condition that he and his successors should retain Courland and Semigallia as a hereditary fief to be held of the crown of Poland. At Wilna, accordingly, where this treaty was concluded in 1561, the master and the principal knights having quitted the habits and ensigns of the order, the investiture of the new dukedom was conferred upon Ketler, who did homage for the same. In 1589, it was enacted by the diet of Poland, that if this fief should be vacated by the extinction of the heirs male of the line of Ketler, the territory held by them should be united to Poland. The republic of Poland was not, however, sufficiently powerful when that event took place to enforce its edict. Courland itself being too small a state to act independently of the great neighbouring kingdoms, the nomination of its dukes, as well as generally the direction of its more important affairs, has been regulated by the will of that power, which at each successive period has had most preponderance in the north. So long as Poland was the great ruling power, Courland was subservient to that republic. When Sweden, under Gustavus Adolphus and his immediate successors, had gained a superiority over Poland, Courland was over-run by the Swedes, and its sovereign led into captivity. The fortune of the house of Vasa having afterwards declined, and the ascendancy having come into the possession of Russia, Courland became almost a province of that power; its dukes were elected and deposed, its councils guided by the influence of the court of St Petersburgh, and its dependence on Poland was no longer any thing more than a mere empty name. As the influence of Russia in Poland began afterwards to be diminished, the duke of Courland proceeded to effect the emancipation of himself and his estate from their absolute dependance on that court. After a succession of vicissitudes, during the progress of which the sovereignty of the duchy was sometimes vested alternately in one or another of different contending competitors; sometimes was altogether without a regular head, while party strove against party within the state, and the desire of regulating its affairs embroiled with it or with each other several of the greater neighbouring powers, the rule of succession was at length established, that the appointment of the dukes should rest with the diet of Courland, but subject to the approbation of the king and republic of Poland. After the conquest and final division of Poland, its feudal dependance on that republic was no longer recognised, and the country was annexed to the empire of Russia. Since that period, (A. D. 1795,) the so much greater affairs which have agitated and engaged all the powers of Europe, and of which the consequence has been an entire change in many parts as to all the existing establishments and relations, though Courland may not have been without its share in the results to which those mighty operations have led, must yet necessarily cause that the interests and the fate of it, as of any other such petty state, can have little in them comparatively to occupy attention. It will remain for the future geographer and historian to collect, as they best may, the meagre details which concern this spot, from amidst the eventful records of the great transactions that had been passing around it, and to fix the limits within which, it may be, it will only be a matter of tradition or of history that it was once contained.

It is to be observed, that the troubles and commotions in which Courland has been so long involved, and by which it has been wasted and destroyed, have been, in a great measure, the consequence of the enormous privileges of its nobles. The internal history of the country is, indeed, little else than a continued series of disputes between them and its dukes; and its boasted liberty has been no other than an aristocratical licentiousness, free itself to commit all kinds of enormities, but holding the rest of the community in a state of the most galling oppression. Here, consequently, as in other countries similarly circumstanced, a declining state of agriculture has been the result of the state of degradation and wretchedness, which has been the unmerited lot of the peasantry. Commerce has languished, because the merchants have been despised; and literature has suffered through the neglect of men of learning. The nobles and gentry were the only landholders, and with this distinction they centered in themselves the whole powers and emoluments of government, and, indeed, enjoyed exclusively the common advantages which are the natural birthright of mankind, and are equally necessary to the happiness of the individual and of society. Such odious slavery is now, however, and has for a considerable period past, been fast losing ground; men are become much more enlightened than they once were; and the time is, perhaps, not far distant, when the citizen, the merchant, the manufacturer, and the peasant, will universally gain that esteem and consequence to which their usefulness and importance in society most justly entitle them.

The population of the duchy of Courland has been estimated to exceed a million and a half.

COURSING. See HUNTING.

Court.

COURT, (*Curia,*) commonly signifies the king's palace, or mansion. But as the king is constitutionally considered as the fountain of justice, and it is extremely probable, if not certain, that, in very early times, our kings often heard and determined causes between party and party in person; the term *court* came to be applied more generally to those places where justice is judicially administered. These judicial establishments must, of course, be various, in regard to their nature and forms of proceeding, according to the different constitutions of government under which they exist. In this article we propose merely to give a short account of the several courts of law in England and Scotland, together with such historical remarks as appear necessary to elucidate the origin and nature of their jurisdiction.

By the ancient constitution of England, as regulated and established by Alfred, the courts of judicature were as numerous as the manors or townships in the kingdom; in order that injuries of every sort might be redressed in an easy and expeditious manner, by the suffrage of neighbours and friends. These small courts, however, communicated with others of more extensive jurisdiction; and these latter with others of still greater power; ascending gradually from the lowest to the supreme courts; which were respectively constituted to correct the errors of the inferior ones; and to determine such causes as, by reason of their importance and difficulty, appear to demand a more solemn discussion. These inferior courts, at least their names and forms, still continue in the legal constitution of England; but as the superior courts of record have in practice acquired a concurrent original jurisdiction with them, and as there is, besides, a power of removing actions thither from the inferior jurisdictions, these petty tribunals have gradually fallen into decay, and now almost into oblivion.

Before we proceed to consider the different species of courts, it may be proper to notice a distinction which runs through them all; viz. that some are courts *of record,* and others *not of record.* A court of record is one in which the acts and judicial proceedings are enrolled in parchment, for a perpetual memorial and testimony; which rolls are called the records of the court, and are of such high and supereminent authority, that their truth cannot be called in question, nor can any plea, or even proof, be admitted to the contrary. All courts of record are the king's courts; and no other court has authority to fine or imprison; so that the very erection of a new jurisdiction, with the power of fine and imprisonment, instantly constitutes a court of record. A court not of record, on the other hand, is the court of a private individual, whom the law does not entrust with any power over the fortune or liberty of his fellow subjects. Such are the courts-baron, and others to be afterwards mentioned, where the proceedings are not enrolled or recorded; but their existence, as well as the truth of the matters therein contained, may, if disputed, be tried and determined by a jury. These courts are not competent to matters cognizable by the common law, unless under the value of 40s. nor to any forcible injury, as they have no process to arrest the person of the defendant.

We shall now proceed to enumerate the several courts of civil, ecclesiastical, military, and criminal jurisdiction. In treating of the civil courts, we shall adopt the order observed by Blackstone; beginning with the lowest, and ascending to those of most extensive power and ultimate resort.

Court of Piepoudre.

1. The lowest and most expeditious court of justice in England is the *Court of Piepowders,* or *Picpoudre,* (*Curia pedis pulverisati,*) supposed to be so called from the dusty feet of the suitors; or, according to Sir Edward Coke, because justice is there done as speedily as dust can fall from the foot. But a more ingenious and satisfactory derivation of the term has been given, from *pied puldreaux,* a pedlar, in old French; and therefore signifying the court of such petty chapmen as usually resort to fairs and markets. It is a court of record, instituted for the purpose of administering justice for all injuries done in that fair or market where it is held. The judge is the steward of him who owns or has the toll of the market. This court has the cognizance of all matters that can possibly arise within the precincts of that fair or market; the plaintiff must make oath that the cause of action arose there; and the injury must be done, complained of, heard and determined, within the compass of one and the same day. From this court there lies a writ of error, in the nature of an appeal, to the courts at Westminster.

Court-baron.

2. The *Court-baron* is a court incident to every manor, and is held by the steward. Its nature is twofold. The one is a customary court, appertaining entirely to the copyholders, in which those matters are transacted which concern their tenures only: (See Copyhold.) The other is a court of common law; the court of the barons or freeholders, in which the steward is rather the registrar than the judge. Its most important business is to determine, by writ of right, all controversies concerning the right of lands within the manor. It has also jurisdiction in personal actions, of debt, trespass, and the like, where the debt or damages do not amount to 40s. The proceedings on a writ of right may be removed into the county court by a precept from the sheriff, called a *tolt, quia tollit atque eximit causam e curia baronum;* and the proceedings in all other actions may be removed into superior courts by the king's writs of *pone,* or *accedas ad curiam.* After judgment, a writ of *false judgment* lies to the courts at Westminster; this not being a court of record.

Hundred-court.

3. The *Hundred-court* is only a larger court-baron, and resembles it in all other respects. It seems to have been derived by Alfred from the institutions of the ancient Germans; mention being made of this kind of jurisdiction, as existing among that people, by Cæsar and Tacitus.

County Court.

4. The *County Court* is a court incident to the jurisdiction of the sheriff. It is not a court of record, but may hold pleas of debt or damages under the value of 40s. The county court may also hold plea of many real actions, and of all personal actions to any amount, by virtue of a special writ called a *justicies.* In this court, the freeholders of the county are the real judges, and the sheriff the ministerial officer.

These are the several common law courts of particular and local jurisdiction. Those of a more general nature, whose jurisdiction extends over the whole kingdom, are 1. The court of *Common Pleas,* or *Common Bench,* (see Common Pleas); 2. The court of *King's Bench,* (see King's Bench); 3. The court of *Exchequer,* and, 4. Of *Exchequer Chamber,* (see Exchequer); 5. The high court of *Chancery,* (see Chancery); 6. The courts of *Assize* and *Nisi Prius,* (see Assize); and 7. The *House of Peers,* which is the supreme court of judicature in the united kingdoms, having no original jurisdiction over causes, but only on appeals and writs of error, to rectify any injustice committed by the courts below.

Besides these courts of common law, there are others

Court.

which take cognizance of matters of an ecclesiastical, military, and maritime nature.

Anciently, there was no distinction between the lay and the ecclesiastical jurisdiction. The bishop of the diocese and the alderman, or, in his absence, the sheriff of the county, used to sit together in the county court, and take cognizance of all causes, ecclesiastical as well as civil. This plan, however, was inconsistent with the policy of the court of Rome, and with the maxims of the canon law, which aimed at making the ecclesiastical independent of the civil power. But this doctrine was not received in England till after the Norman conquest, when William I. in favour of the clergy, separated the ecclesiastical from the civil jurisdiction. The union of the two courts was afterwards restored by king Henry I. upon his accession, conformably to the ancient law of the kingdom; but this measure was early disapproved of by the Popish clergy, who, under the direction of that arrogant prelate Archbishop Anselm, in their synod at Westminster, 3 Hen. I. ordained, that no bishop should attend the discussion of temporal causes, which soon dissolved the recent union. When, upon the death of Henry, the usurper Stephen was brought in and supported by the clergy, one article of the oath which they imposed upon him was, that ecclesiastical persons and ecclesiastical causes should be subject only to the bishop's jurisdiction; and the two courts have ever since continued distinct.

Ecclesiastical courts.

Of the ecclesiastical courts, or courts *Christian*, as they are often called, 1. The *Archdeacon's* court is the lowest. In the archdeacon's absence, this court is held before a judge appointed by him, called his *official*. By the statute 24 Henry VIII. an appeal lies from thence to, 2. The *Consistory* court of the diocesan bishop, of which the bishop's chancellor, or his commissary, is the judge. From this court there lies an appeal by the same statute to, 3. The court of *Arches*, which is a court of appeal belonging to the archbishop of each province. In this court, the archbishop's principal official receives and determines appeals from the sentences of all inferior ecclesiastical courts within the province. From him there lies an appeal, by statute 25 Hen. VIII. c. 19, to the king in chancery. 4. The court of *Peculiars* is a branch of the court of arches, which has jurisdiction over all those parishes dispersed through the province of Canterbury, in the midst of other dioceses, which are exempt from the ordinary's jurisdiction, and subject to the metropolitan only. By the statute 25 Hen. VIII. c. 12, an appeal lies from this court to the king in chancery. 5. The *prerogative* court takes cognizance of all testamentary causes; the probate of wills belonging to the archbishop of the province, by way of special prerogative. The judge of the prerogative court is appointed by the archbishop, and an appeal lies from him, by the statute 25 Hen. VIII. c. 19, to the king in chancery. The great court of appeal, in all ecclesiastical causes, is 6. The court of *Delegates*, consisting of lords spiritual and temporal, judges of the courts at Westminster, and doctors of the civil law. (See Appeal.) 7. A *commission of review* is sometimes granted, in extraordinary cases, to revise the sentence of the court of delegates.

Military Court.

The only military court established by the laws of England is the court of *Chivalry*, which was formerly held before the high constable and earl marshal of England jointly; but since the extinction of the former office, in the reign of Henry VIII. it has usually, with respect to civil matters, been held before the earl marshal only. This court has cognizance of contracts and other matters touching deeds of arms and war, and was in great repute during the times of pure chivalry, but is now grown almost entirely out of use. An appeal lies from its sentences to the king in person.

Maritime Courts.

The maritime courts, having jurisdiction in injuries arising upon the seas, or in parts out of the reach of the common law, are the court of *Admiralty*, and its courts of appeal. The court of admiralty is held before the lord high admiral of England, or his deputy. It is usually held at Doctors' Commons in London, and its proceedings are according to the civil law. From the sentences of the admiralty judge, an appeal lies to the king in chancery.

Private Courts.

There are also a number of courts of private and special jurisdiction in England, some of which are now fallen almost entirely into disuse. Such are, 1. The *forest* courts, instituted for the government of the king's forests in different parts of the kingdom; and for the punishment of all injuries done to the king's deer or *venison*, to the *vert* or green swerd, and to the covert in which the deer are lodged. These are the courts of *Attachments*, of *Regard*, of *Sweinmote*, and of *Justice seat*. Since the revolution in 1688, the forest courts have fallen into total disuse. 2. Another species of private courts is that of *Commissioners of sewers*, appointed by a commission under the great seal, at the nomination of the lord chancellor, lord treasurer, and chief justices, pursuant to the statute 23 Hen. VIII. c. 5. This court is subject to the controul of the court of King's Bench. 3. The court of *Policies of insurance*, also appointed by commission; but on account of its limited jurisdiction, it has fallen into disuse; and no new commission has of late years issued. 4. The court of the *Marshalsea*, and the *Palace court*, courts of record instituted for the purpose of hearing and determining causes between the servants of the king's household, and others within the verges. These courts are held once a week in the borough of Southwark, and a writ of error lies from thence to the court of King's Bench. 5. The courts of the *Principality of Wales*, whence writs of error lie to the King's Bench. 6. The court of the *Duchy of Lancaster*, which does not appear to be a court of record. 7. The courts of the *Counties palatine of Chester, Lancaster, and Durham*, and the court of the *Cinque Ports*. 8. The *Stannary* courts in Devonshire and Cornwall, for administering justice among the tinners. No writ of error lies from them to the courts at Westminster, but an appeal from the steward to the under warden; from him to the lord warden; from thence to the privy council of the Prince of Wales, as Duke of Cornwall; and from thence to the king. 9. The several courts within the city of London, (such as the sheriff's court, and the court of hustings,) and other cities, boroughs, and incorporations throughout the kingdom, which are held by prescription, charter, or act of parliament. The most remarkable species of courts of this description, are the *Courts of Requests and of Conscience*, for the recovery of small debts, of which there was one erected in London, by an act of the common council, so early as the reign of Henry VIII. and confirmed by the statutes 1 Jac. I. and 3 Jac. I. c. 15, since explained and amended by 14 Geo. II. c. 10. According to the constitution of this court, two aldermen and four commoners sit twice a week to hear all causes of debt, not exceeding the value of 40s. which they examine in a summary way, by the oath of the parties, or other witnesses, and make such order therein as is consonant to equity and good conscience. Several other courts of conscience have been since erected, on the same plan, in other places. 10. The last species of private courts which we shall mention is the

Chancellor's court, in the universities of Oxford and Cambridge, which enjoy an exclusive jurisdiction in all civil suits, where a scholar or privileged person is one of the parties. The process in this court is much conformed to the civil law. These privileges were contained in their several charters, and confirmed by the statute 13 Eliz. c. 29. The jurisdiction is exercised at Oxford in the chancellor's court, by the vice-chancellor, his deputy, or assessor; from whom an appeal lies to delegates appointed by the congregation; from thence to other delegates of the house of convocation; and if all the three concur in the same sentence, it is final by the statutes of the university, according to the rule of the civil law. But if there be any discordance, an appeal lies, in the last resort, to delegates appointed by the crown under the great seal in chancery.

Courts of criminal jurisdiction in England.

The courts of criminal jurisdiction in England are, 1. The high court of *Parliament*; which proceeds in the trial of great and enormous offenders, whether lords or commoners, by the method of impeachment. 2. The court of the *Lord High Steward* of Great Britain; which is a court instituted for the trial of peers indicted for treason or felony, or for misprision of either: (See IMPEACHMENT, PARLIAMENT, PEERS, *House of*, and STEWARD, *High*.) 3. The court of *King's Bench;* which is the principal court of criminal jurisdiction in England: (See KING'S BENCH.) 4. The court of *Chivalry*; whose criminal as well as civil jurisdiction is fallen into entire disuse. 5. The high court of *Admiralty*: (See ADMIRALTY, *Court of*.) 6. The court of *Oyer* and *Terminer*, and general *Gaol Delivery*; which is held before the king's commissioners, among whom are usually two judges of the courts at Westminster, twice in every year, in every county of the kingdom; except the four northern counties, where it is held only once; and London and Middlesex, where it is held eight times: (See ASSIZE and CIRCUIT.) 7. The court of general *Quarter Sessions* of the peace, which is held before two or more justices of the peace, of whom one must be of the quorum, once in every quarter of a year, for the purpose of trying small felonies and trespasses: (See JUSTICE *of the Peace*.) 8. The *Sheriff's Tourn* is a court of record, held twice every year before the sheriff, in different parts of the county. Out of it arose, 9. The *Court-leet*, or *View of Frank-pledge;* which is also a court of record, held once a year within a particular hundred, lordship, or manor, before the steward of the leet. Its jurisdiction extends to the preservation of the peace, and the punishment of sundry minute offences against the public good. This court, however, has grown into disrepute; and its business has, for the most part, gradually devolved upon the Quarter Sessions. 10. The court of the *Coroner:* (See CORONER.) 11. The court of the *Clerk of the Market* is a court incident to every fair and market, to punish misdemeanors committed there, as the court of *Piepoudre* determines disputes relative to private property. The principal object of the jurisdiction of this court is to take cognizance of weights and measures.

There are some other private or special courts of more partial jurisdiction in criminal matters; such as, 1. The court of the *Lord Steward, Treasurer*, or *Comptroller* of the King's Household, which takes cognizance of felony, by any of the king's servants under the degree of a lord, in confederating, compassing, conspiring, and imagining the death of the king, or any of the privy-council, &c. The proceedings in this court are according to the course of the common law. 2. The court of the *Lord Steward of the King's Household*, erected by the statute 33d Henry VIII. c. 12. to hear and determine all treasons, misprisions of treason, murders, man-slaughters, bloodshed, &c. committed in any of the palaces or houses of the king, or in any house where he may happen to reside. One part of the punishment for shedding blood in the king's court is to cut off the hand of the offender; a ceremony which is minutely prescribed by the statute above mentioned. 3. The courts of the universities have jurisdiction in criminal offences under the degree of treason, felony, or *mayhem*. The trial of these crimes is committed, by a particular charter, to the court of the *Lord High Steward of the University*.

Courts of law in Scotland.

Since the abolition of the ancient heritable jurisdictions, the principal courts of law in Scotland are, 1. The *Court of the Baron*, whose jurisdiction was formerly pretty extensive, but is now, by the statute 20th Geo. II. c. 43. limited to the right of recovering from his vassals and tenants the feu-duties and rents of the land, and compelling them to perform the services to which they are bound, and to the right of determining civil questions, not exceeding the value of 40s. His criminal jurisdiction is confined to assaults, batteries, and smaller offences; but this jurisdiction is subject to such restrictions, that it is never exercised by the baron. 2. The *Borough Courts*. Bailies of boroughs take cognizance of matters of debt, services, and questions of possession between the inhabitants; and their criminal jurisdiction extends to petty riots, and to reckless (not intended) fire-raising. The court of the *Dean of Guild* has the cognizance of mercantile causes within boroughs, and the inspection of buildings, &c. 3. The courts of the *Justices of the Peace*. 4. The court of the *Sheriff*, or his Substitute: (See SHERIFF.) 5. The *Consistorial* or *Commissary* Court, which came in place of the Bishop's Court, and has an exclusive jurisdiction in ecclesiastical causes. 6. The court of the *High Admiral*, whose civil jurisdiction extends to all maritime causes; and in criminal cases, to all crimes committed upon the seas, on fresh water within flood-mark, and in all harbours or creeks: (See ADMIRALTY COURT.) 7. The Court of Exchequer, which takes cognizance of all matters concerning the revenue: (See EXCHEQUER.) 8. The Court of *Justiciary*, which is the supreme court of criminal jurisdiction in Scotland. It received its present form by the act 1672, c. 16. and consists of five of the lords of session, joined to the justice-general and justice-clerk, of whom the justice-general, and in his absence the justice-clerk, is president. The jurisdiction of the Court of Justiciary extends to all crimes committed throughout the kingdom. By the statute 20th Geo. II. c. 43, the lords of justiciary are directed to hold circuit courts regularly twice a year, in spring and in autumn; and, by the 23d Geo. III. c. 45, they are to continue in each town in the circuit at least three days, and in no case to leave any trial that has been commenced undecided: (See CIRCUIT and APPEAL.) 9. The *Court of Session* is the supreme court of civil jurisdiction in Scotland. It was instituted in the reign of King James V. in place of the daily council, and in imitation, it is said, of the parliament of Paris. The judges originally consisted of seven churchmen, and seven laymen, besides the president; and from the act 1579, c. 93, it appears that the president must have been chosen from among the churchmen. But by 1640, c. 26, churchmen were excluded from admission to the bench, and the distinction of spiritual and temporal judges was suppressed. Besides the fifteen ordinary judges, the king was anciently allowed to name three or four lords of his great council, who might sit and vote with them; but by the statute 10th Geo. I. the power of naming these extraordinary lords was renounced. The number of judges is therefore fifteen, of whom nine are a quorum. By the late statute 48th Geo. III. the constitution of the Court of Session received several essential alterations; the most important of which was its separation into two divisions or chambers; the first consisting of the lord president and seven of the other judges, the second of the lord-justice-clerk and six judges Several other material alterations have been adopted, of which we shall have occasion to speak in a future article.

Court-martial.

Court-martial is a court authorised by the mutiny act, for the trial of crimes committed by officers or soldiers in his Majesty's service. A court-martial must consist of at least thirteen judges, all commission officers, of whom the president must be a field-officer. The jurisdiction of this court extends only to points of military discipline; for in all other matters the military are amenable to the ordinary courts of law. No appeal lies against the sentence of a court-martial. It is reported to the king, from whom alone any change or alleviation is to be obtained. Courts-martial, in the sea service, are regulated by the statute 22d Geo. II. c. 33. See Blackstone's *Comment.* b. iii. ch. 3, 4, 5, and 6, and b. iv. ch. 19; Jacob's *Law Dict. v.* COURT; and Erskine's *Inst. of the Law of Scotland,* b. i. tit. 3. and 4. (z)

COURTRAY, CORTRYCK, *Corturiacum,* a town of France, in the department of the Lys, is situated upon the river Lys, which passes through the town. Courtray has been long celebrated for its manufactures, which are still carried on to a very considerable extent. The flax which grows in the neighbourhood has the character of being the strongest and the finest in Europe; and, from the great attention which has been paid to the processes of weaving and bleaching, the goods which are manufactured from it, are particularly celebrated, and find a ready sale. The manufacture of linen cloth, and table linens, is carried on to a great extent, and the latter are made with every possible variety of patterns. The lace which was made here, in imitation of that of Valenciennes, had a great demand both in France and England, and the manufacture of guingams and siamoises is briskly carried on. There are also in this town 22 bleachfields, 17 for linens, and five for thread, three houses for refining sugar, several soap-works, starch manufactories, breweries, and a manufactory for earthen ware, which is in great estimation. Population 13,372. (π)

COUTANCES, *Constantia,* a town of France in the department of La Manche, situated partly on a plain and partly upon a hill, between the rivers Soulle and Bulsare, about two leagues from the embouchure of the former into the ocean. The cathedral of Coutances is reckoned one of the finest Gothic buildings in Europe; but the town is principally celebrated for its trade and manufactures. Although this town is peculiarly fitted for carrying on the woollen manufacture on a very extensive scale, yet woollen goods are made to a very small extent. Druggets made of the wool of the country, and for the dress of the peasants, and a few other woollen goods, are the only articles of this kind which are made at present. The tanneries of this town, which are established in the Fauxbourg of Soulle, are numerous, and the skins are sent to Paris. Parchment is also manufactured at Coutances. The trade of the place consists chiefly of corn, butter, poultry, horses and cattle. Population 8507. (π)

COUTAREA, a genus of plants of the class Hexandria, and order Monogynia. See BOTANY, p. 194.

COUTOUBEA, a genus of plants of the class Pentandria, and order Monogynia. See BOTANY, p. 132.

COW. See DAIRY and MAMMALIA.

COWBRIDGE, the name of a market-town in South Wales, in the county of Glamorgan, situated in a fertile and delightful valley called the vale of Glamorgan. The town, which consists of one street about three quarters of a mile long, is tolerably well built, though badly paved, and has a town hall where the quarter sessions are annually held, a county bridewell, and a handsome parish church. One of the gates of the ancient stone walls, which was built in 1091 by Robert de St Quintin, still remains, and adorns the part of the town where it stands. The free school of Cowbridge was endowed by Sir Llewellyn, or Leolinus Jenkins, secretary of state in the reign of Charles II. "He was not," says Mr Malkin, "as has been erroneously stated, the founder; but, on the contrary, his benevolence was probably directed to this object by the recollection that he had derived the first elements of his great knowledge from this source. He may, however, be considered here also as a second founder, for it is to him that the young men on the foundation owe, in addition to a small annual stipend while at school, the probability of enjoying considerable advantages in Jesus College, Oxford, where there are two fellowships, two scholarships, and an exhibition, exclusively confined to students educated at this school. Its literary reputation has kept pace with its academical advantages, under a succession of able masters." There is likewise at Cowbridge a good school for reading, writing, and accounts. The Glamorganshire races are held on the heath, near Cowbridge, and at Cardiff, alternately. There are no manufactories in Cowbridge, but it appears to have been once of much greater extent, and to have had a monastery, which is said to have been converted into an university. The town is governed by two bailifs, 12 aldermen, and 12 common-council men. Population, in 1811, 850. Number of houses 166. See Malkin's *Scenery, Antiquities, and Biography of South Wales,* vol. i. p. 179, 180, and vol ii. p. 538; and Evan's *Cambrian Itinerary.* (w)

COWES. See WIGHT, *Isle of*

COWLEY, ABRAHAM, was the posthumous son of a grocer in London, and was born in 1618. His mother, though left a poor widow, found means to get him educated at Westminster-school, and he afterwards obtained a scholarship at Cambridge. In the window of his mother's apartment lay Spenser's Fairy Queen, in which he very early took delight to read, till, by feeling the charms of verse, he became, as he relates, irrecoverably a poet. He was indeed one of those poets who lisped in numbers. At ten years old, he wrote his tragic history of Pyramus and Thisbe, and at fifteen published a volume of poetry. At Cambridge, while yet a young student, he wrote the greater part of his Davideis, and published his comedy of Love's Riddle, with another in Latin, entitled the *Naufragium Joculare*; and, for the entertainment of the prince, as he passed through Cambridge on his way to York, drew the rough sketch of a piece called the Guardian, which was repeated by the scholars. In 1643, being now master of arts, he was ejected from the university by the parliamentary visitants, and taking refuge at Oxford, assailed his public enemies in a satire, entitled the Puritan and Papist.

From a sufferer he became a writer and an actor in the royal cause, followed the queen to Paris, became secretary to the Earl of St Albans, then Lord Jermyn, performed some confidential journies in the cause, and devoted his days, and frequently nights, in decyphering the correspondence of the king and queen. When his services were no longer necessary at Paris, he was, in 1656, sent back to England, according to Sprat, that, under pretence of privacy, he might take occasion of giving notice of the posture of things in this nation. This account, if true, places Cowley under the equivocal denomination of a spy in his native country. It was espionage, however, in a cause which he had embraced from principle, and there is no evidence that he practised it with arts of simulation degrading to his character. On his return, he was seized by the messengers of government in their search for another person, was put in prison, and not released till he found bail to the amount of £1000. His pursuits in England were sufficiently pacific; he published an edition of his poems, took the degree of a physician, and became a member of the newly instituted Philosophical Society. He seems not to have attempted the practice of physic; but having entered on botany as a preparatory study, he composed in Latin several books of botanical poetry.

At the dissolution of government, which followed the death of Oliver, he returned to France, where he resumed his former station, and staid till the restoration. Expecting from that event to be recompensed for his long fidelity and services, by the mastership of the Savoy, which had been promised to him successively by the two Charles's, he experienced great mortification from the neglect of the court. To increase his chagrin, his comedy entitled *Cutter of Coleman Street*,* which being falsely supposed a satire on the royal party, was severely received on the stage. In the dejection of mind occasioned by those events, he published his Complaint, in which he styles himself the melancholy Cowley. At length, through the interest of the Duke of Buckingham and the Earl of St Albans, he obtained a lease of a farm at Chertsey, held under the queen, by which his income was raised to about £300 per annum. A country retirement had been, from early youth, a real or imaginary object of his wishes, and had been a frequent theme of his prose as well as his verse. He retired first to Barn-elms, on the banks of the Thames; but this not agreeing with his health, he removed to Chertsey. Here he did not live long to experience either the enjoyments or discomforts of rustication. According to Sprat, the disorder which carried him off, was an affection of the lungs, contracted by staying too late in the fields among his labourers. But Mr Warton, on the authority of Spence, informs us, that Cowley paid a visit on foot, in company with the same Dr Sprat, to a gentleman in the neighbourhood of Chertsey, which they prolonged in free conviviality till midnight, and that missing their way on their return, they were obliged to pass the night under a hedge, which gave the poet a severe cold and fever, that terminated in death. He died on the 28th of July 1667, in the 49th year of his age, and was interred in Westminster Abbey, near the remains of Spenser and Chaucer.

Cowley is confessedly the best English poet in that class which has now prescriptively acquired the title of metaphysical. Their popularity in Europe may be traced to the fountain head of Italian poetry in Petrarch; but their characteristic perversities in bringing together remote analogies, and prolonging similitudes between material and mental objects, and substituting extravagant conceits for the genuine language of poetry and passion, are all found in equal perfection of absurdity among the ancestors of the Petrarchan school, namely, the troubadours or provincial poets, to the study of whom Petrarch was certainly addicted. This character of the troubadours, however, applies only to the later and more degenerate class of troubadours. In the earlier part of the middle ages, allegory was the favourite strain of European poetry, imbibed from the predilection of the learned for Boëthius. When the provincial bards found allegory inconvenient for their *sirvettes* or shorter effusions, they substituted protracted metaphor in the place of allegory, and supplied the fathers of Italian verse with those specimens of overlaboured figures which load and deform the tissue of Petrarch's and Marino's muse. In like manner, the metaphysical or conceitedly metaphorical school succeeded in England to the allegorical school of Sackville and Spenser. Donne, Drayton, Crawshaw, and Cowley, were the most ingenious poets of this dynasty, whose reputation suffered indeed in some degree from the rivalship of Denham and Waller, in a smoother, terser, more regular, and more majestic walk of poetry, but whose decline was only accomplished by the slowly rising reputation of Milton, and the more immediate popularity of Dryden. It is not our design to characterise more particularly any of the metaphysical school excepting Cowley. His defects, though strictly referable to that school, are intermingled with beauties of the most original unquestionable stamp. True it is, as the profligate Rochester said, his style not being of God, (we ought to substitute the word nature,) could not stand. But though no poet goes more extravagantly out of nature, there is none who occasionally lights on more naïve and natural expressions. Like a true metaphysical poet, he is for ever drawing upon his *learning* for the remote images which his fancy combines; but while he is racking his head for some far-fetched idea, he anon seems to start a thought from the very centre and core of his heart and feelings. As an instance of this, we may dip at hazard into his pages, and select his little poem on Friendship in Absence as an instance. After a string of forced and quaint ideas, in which he tells his friend,

> "By every wind that comes this way,
> Send me at least a sigh or two,
> Such and so many I'll repay,
> As shall themselves make winds to get to you;"

who would expect from such a prelude so beautiful and appropriate a thought as the concluding stanza.

> "And when no art affords me help or ease,
> I seek with verse my griefs t' appease;
> Just as a bird that flies about,
> And beats itself against the cage;
> Finding at last no passage out,
> It sits and sings, and so o'ercomes its rage."

The style of Cowley, keeping his matter distinct from his ideas, is easy, even to carelessness. Donne and Crashaw, among the poets of this school, were harsh and laborious in their structure of style; but Cowley rambled into what he called the Pindaric manner, which, though the remotest in the world from Pindar,

* The title of the play was without the article *the*, and is called "Cutter of Coleman Street," because a merry sharking fellow about town is the principal character in it.

Cowper.

was at least free from inversions; and if loose, negligent, and even slovenly, was at least free from the opposite extreme of stiffness,—a fault which often haunts correcter and terser poets.

Dr Hurd did considerable service to Cowley's memory, by selecting the best of his poems, or, more properly speaking, those of his pieces which are legible as entire poems. It was not, however, in the power of that or any other critic, to disengage all the genuine ideas of superlative poetical fancy, which sparkle like minute fragments of gold amidst the general dross of his composition. To have presented all his beauties, he must have culled broken sentences, which would be scarcely intelligible in a detached shape. After pages of dulness, we come to such striking thoughts, as when he apostrophises Hope,

> Brother of Fear more gaily clad,
> The merrier fool of the two, yet quite as mad.

He is never sublime, and neither his subjects nor his genius seem to have favoured the deep and genuine pathetic. But his fancy flutters on a gay and dazzling, though often fantastic wing. A gay, exhilarating, and elastic spirit of poetry supports him, without a single descent, throughout the whole of some of his pieces; as in his Ode to Wit, and his Chronicle, the latter of which productions Johnson characterizes with an eloquence which does equal honour to the poet and the critic: "The Chronicle is a composition unrivalled and alone; such gaiety of fancy, such varied similitude, such a succession of images, and such a dance of words, it is impossible to expect except from Cowley. His strength always appears in his agility—his volatility is not the flutter of a light, but the bound of an elastic mind. His levity never leaves his learning behind it —the moralist, the politician, and the critic, mingle their influence even in this airy frolic of genius. To such a performance Suckling could have brought the gaiety, but not the knowledge. Dryden could have supplied the knowledge, but not the gaiety." It is impossible to select such a paragraph from Johnson, without exclaiming, with reference to his criticisms, *O si sic omnia!* (*η*)

COWPER, William, an eminent English poet, was born at Berkhamstead in Hertfordshire in 1731. His father, the rector of that parish, was the son of Judge Cowper, of the Court of Common Pleas, and a nephew of the Lord Chancellor Cowper. The mother of the poet died when he was only six years of age, but he describes her as if his tender memory, and not his imagination, had supplied the poetical portrait. At an early age he was sent to Westminster school, a scene of bustle and contention peculiarly ill fitted for his sensibility. The recollection of his sufferings under his school-boy tyrants at that place, seems to have embittered his opinion of public education through life. At eighteen he was sent from Westminster to the house of a Mr Chapman, a London law-solicitor, who by his own account paid little or no attention to the profession. His next removal was to chambers in the Inner Temple; but still his aversion to dry study, probably occasioned by his constitutional melancholy, and his predilection for polite literature, prevented his progress and hopes in the legal profession. He was not, however, wholly idle, but wrote from time to time translations from Horace, occasional poems, and some prose papers, which appeared in the Connoisseur, and have been deservedly noticed for their ease and elegance of style. To these writings he did not give his name.

When turned of 30, having cherished a strong attachment for a lady of great accomplishments and beauty, (the object of his affections is said in common report to have been a sister of Lady Hesketh), he looked forward to a happy settlement for life, and was appointed to be the reading clerk of the private committees of the House of Lords; but on account of his great dread of public appearance, the situation was changed to the clerkship of the Journals of the same House. Even in this appointment, however, an unlucky dispute in Parliament required his standing a public examination; and though he had prepared himself for months by studying the Journals, he was so fearful of his memory failing, that he could not make the experiment. Under the terrors and regret attending this disappointment, the fine fabric of his mind was overthrown, and it was necessary to remove him to St Alban's, to be under the care of Dr Cotton, with whom he continued 19 months. Removing to Huntingdon, for the sake of being near his brother, a clergyman and fellow of Cambridge, he fell into intimacy with some inhabitants of that place, who certainly contributed to deepen the shade of that religious melancholy which had sprung up in his mind since his recovery. The younger Mr Unwin, the son of a clergyman of Huntingdon, made acquaintance with Cowper one day after church, and introduced him to his mother, Mrs Unwin, the future Mary of the poet, and to the elder Mr Unwin who was still alive. He was soon domesticated in the family of the Unwins, and his routine of life among these well-meaning enthusiasts is thus described: "We breakfast," says Cowper in one of his letters," commonly between eight and nine; till eleven we read either the scriptures, or the sermons of some faithful preacher of those holy mysteries. At eleven we attend divine service, which is performed here twice every day, and from twelve to three we separate and amuse ourselves as we please. During that interval I either read in my own apartment, or walk or ride, or work in the garden. We seldom sit an hour after dinner; but, if the weather permits, adjourn to the garden, where, with Mrs Unwin and her son, I have generally the pleasure of religious conversation till tea-time. If it rains, or is too windy for walking, we either converse within doors, or sing some hymns of Martin's collection, and, by the help of Mrs Unwin's harpsichord, make up a tolerable concert, in which our hearts, I hope, are the best and most musical performers. After tea we sally forth to walk in good earnest, (Mrs Unwin is a good walker,) and we have generally travelled above four miles before we see home again. When the days are short, we make the excursion in the former part of the day between church-time and dinner. At night we read and converse as before till supper, and commonly finish the evening either with hymns or a sermon, and last of all the family are called to prayers." On the death of the elder Mr Unwin, he removed with the family to Olney in Buckinghamshire. Here the society of Mr Newton, a person of the same principles with the Unwins, contributed to fix his mind, without variety or relief, on those awful subjects, which, however proper to be recalled to the careless and insensible, are most dangerous to a diseased mind like Cowper's, whose distemper was religious madness, and whose constant melancholy rose from an idea that he was the only soul in the universe who was to be excluded from the system of divine mercy.

In 1773 his tremendous malady returned, and lasted for nearly eight years. When his mind had broken through its long eclipse, he came before the world, for the first time, as an avowed author, at the age of 50. The reception of his first volume was not so popular as it deserved to be, considering the truth, originality, and pathos, of many of his sentiments and descriptions, probably owing to the puritanical tone of religious austerity, and the harshness of versification, which obscured its beauties. In the same year (1781) that his volume appeared, the accomplished Lady Austen came to Olney. Her vivacity and colloquial powers seem to have fascinated Cowper, and her goodness of heart to have gained his warmest friendship. At her instance he commenced the poem of the Task. Cowper had complained of the difficulty of finding a subject. Lady Austen told him that he could be in no want of a subject; you can write (said she) upon any thing, "write upon this sopha." Cowper adopted the subject, probably intending at first (as the introductory lines seem to shew) a mock heroic effusion; but led by that boundless power of association, by which he could link the most serious moral to trivial circumstances, he soon left the insignificant subject from which he had started, to expatiate over the whole field of moral sentiment and picturesque description. It is painful to think, that the jealousy of Mary Unwin compelled him to renounce the friendship of Lady Austen. The Task was finished in 1783, and he had scarcely finished it when he commenced translating Homer into blank verse, which was finished in 1791, and published by subscription. After this he accepted of a literary engagement from Johnson the bookseller, to make a version of Milton's Italian poetry, and write a commentary on his whole works. To this engagement he had, unfortunately, for the rest of his life but little serenity of mind to apply. His mental depression returned in 1792, and continued severely during the following year. As Mary Unwin had now become paralytic, Cowper's kinswoman, Lady Hesketh, undertook, with great kindness, the management of his household. In 1794, Mr Hayley, a friend in whom the poet had much delighted in the days when he possessed his faculties, came to visit him; but Cowper was now so sunk in melancholy torpor, that he expressed no joy at the sight of him; and when the news of his Majesty having settled a pension on the unhappy sufferer was announced, it gave him no visible pleasure. In 1795 he was removed from Olney, together with Mrs Unwin, to the house of his relation at Tuddenham, the Rev. Mr Johnson. Stopping on the journey at the village of Eaton near St Neot's, he walked with his young kinsman in the church-yard by moonlight, and talked of the poet Thomson with more composure than he had shewn for several months. Soon after he visited his cousin Mrs Bodham at Mattishall, when he saw in her house his own portrait by Abbot; he clasped his hands in an agony of grief, wishing that his present sensations could be what they were when that picture was painted.

Some dawnings of restoration shewed themselves in the summer of 1796, but disappeared again in the autumn. Mrs Unwin expired at the house of Mr Johnson at East Dereham in the December of that year. Cowper had seen her about half an hour before her expiration. In the dusk of the evening he accompanied Mr Johnson to survey the corpse; but after looking at it a few minutes, started away with an unfinished exclamation of grief, and either from fear to trust his lips with her name, or forgetting her from mental alienation, never afterwards spoke of her. In 1799, he resumed some power of exertion; he revised his Homer, made some translations, and composed his last and affecting original poem the Cast-away. The dismally despondent tone of that effusion shews that his melancholy was not abated by the last blaze of his intellectual faculties. In 1800 the dropsy, which had before appeared, shewed fatal symptoms of progress in his constitution, and he expired, after a rapid decline, on the 25th of April of the same year.

Cowper's publication of the Task, set him at least upon a par with any of his contemporaries in poetry, and perhaps superior to them all except Burns. Though he has not aspired to the first rate powers of poetic creation, in inventing incident and embodying characters, his pages are full of scenery and pictures of life and manners, dignified by the highest sentiments, and made interesting by the most tender touches of the social affections. If we miss in him the fairy enchantment of colouring which Thomson throws over the face of Nature in his descriptions, we have a plain fidelity to those minute features which are lost in the dazzling halo with which the former poet surrounds her. All is rapture and enthusiasm with Thomson. The result of Cowper's views is a calmly pleasing entertainment. Before Cowper, the English poets leant to the side of excessive embellishment in describing nature, and seemed to be shy of approaching rustic and ordinary life, except to burlesque it on the stilts of mock heroic, or to mask her homeliness either under Gothic antiquity of language, or the still more disgusting form of Arcadian pastoral. Cowper making an irresistible appeal to the interest which the human heart feels in whatever is human, took for subjects those humble and homely circumstances which create a pleasant association throughout the whole range of life and manners, with a gravity which gave them due importance, but with a familiarity of style also which suited their plainness. He reserved to himself, however, a chaste and sober dignity for higher subjects, in which there is a freer admixture of what is commonly called the language of poetry as distinguished from prose. This elevation, it is true, he but occasionally exercises; and we often find him in high regions of thought and sentiment, checking the sublimity of his flight by vulgar and familiar phraseology. In taking away the polish and colouring of poetical diction, he often leaves his style cadaverous and rugged. His sketches from humble nature are also frequently prolonged to tiresome minuteness, and lowered to objects with which poetry disdains alliance. His pictures of the Dung-bed, and the Gin Shop, and his Snoring Sick Nurse, are in this Dutch taste. A most unfortunate fault is, that the highest fire of his enthusiasm is so frequently mixed with the clouds of methodism and mysticism. The man was elevated and pure himself, but he assumes a character not his own, when he illustrates the depravity of the human race by the dressy propensity of a country girl wearing ornamental curls upon her head, for which she is "*indebted to some smart wig-weaver's hand.*" His contempt of what he calls the vanity of philosophy, also betrays an illiberality inexcusable even in a visionary recluse. His lighter pieces evince the finest conformation of social and domestic feelings which probably human beings ever possessed, and an exquisite talent for humour. His great translation has something of the bony and muscular greatness of the Grecian bard, but it is, in general, less like *Homer revived* than *Homer dug out of his grave.* (*n*)

COWPOX. See VACCINATION.

CRACKS. See VETERINARY MEDICINE.

CRACOW, CRACOVIA, *Carrodunum*, the ancient capital of Poland, is now a town of Austria, and the capital of West Gallicia. It is situated on an extensive plain upon the Vistula, near its confluence with the small river Rudowa. The city and the suburbs occupy a large tract of ground, but the houses are thinly scattered, and contain few inhabitants. Many of the streets are wide and handsome, and the great square, which contains several well-built houses, is very spacious; but, in consequence of the devastations which this city experienced from the Swedes at the beginning of the last century, and more recently from the Russians, it has the appearance of a magnificent capital in ruins. The number of uninhabited houses, the effects of cannon, grape, and musket shot on the walls, and the marks of ruined grandeur which everywhere appear, form a striking contrast with the splendour and beauty of the churches, which seem to have escaped the general ruin. The lofty brick walls with which Venceslaus surrounded the town, are defended by round and square towers of the most ridiculous shapes, and in the old style of fortification.

The principal public buildings are the palace or citadel, the university, the cathedral church, the palace of Casimir the Great, the observatory, the botanical garden, the library, and the hospital.

The palace or citadel, which was built by Ladislaus Jaghellon, and was the residence of the Polish king, is situated on the summit of a rock towards the southern part of the town near the Vistula, and is encircled with brick walls and old turrets. The greater part of it was destroyed by Charles XII. after the battle of Clissow. The few rooms which remain are very large and magnificent, but without furniture. The apartments are principally remarkable from their commanding an extensive view of the surrounding country. Two large barrows are particularly visible, and are supposed to be the sepulchres of Cracus, duke of Poland, and his daughter Venda. The fortress of Landskron, situated upon a rock, is also visible from the palace.

The university of Cracow was founded and endowed in 1342 by Casimir the Great, and was completed by Ladislaus Jaghellon. In 1778, the number of students was 600. The library presented nothing remarkable but a Turkish book found among the spoils of the battle of Chotzim, and presented by John Sobieski.

The cathedral, which is a fine building, contains an immense number of monuments erected to the memory of the Polish kings. A number of bones, which the vulgar believe to have belonged to giants, are suspended from the roof of the cathedral. The sepulchres of the kings of Poland are not remarkable for their magnificence. Some of them are without inscriptions, and in general the figure of the king is carved in marble, of very common workmanship. The mausoleum of John Sobieski, and the tomb of S. Stanislaus are particularly interesting. The cloister of the Franciscans is deserving of notice, and the wainscoating of the choir, which is incrusted with mother-of-pearl, is reckoned a piece of beautiful workmanship.

The palace of Casimir the Great, which is an old ruined structure, is in the neighbourhood of Cracow. "In the inner court," says Mr Coxe, "are the remains of a corridore, with pillars of the Doric order; and upon a side wall, I observed the white eagle of Poland carved in stone, and around it an inscription so much defaced that I could only make out ANN. DOM. M.CCCLXVII, which answers to the æra of Casimir, who died in 1370. Several marble columns were scattered around, which shewed the ancient magnificence of the building. The greater part of the fabric was evidently of later date than the reign of Casimir, and probably constructed by succeeding sovereigns upon the foundation of the ancient palace; perhaps by Stephen Bathori, from the inscription, STEPHANUS DEI GRATIA, which I traced; and also by Sigismund III. as I discovered his cypher, with the wheat sheaf, the arms of Gustavus Vasa, from whom he was lineally descended." In the garden is a barrow, which is said to be the tomb of Esther the Turk, who was Casimir's mistress. Casimir made this palace his principal residence.

The most interesting objects in the vicinity of Cracow, are the chateau and park of Pulawy, belonging to the Princess Czartoriska, and the salt mines of Wielitzka. The mines, which are only an hour and a half's ride from the town, are 743 feet deep, 1115 feet broad, and 6691 long. Visitors descend upon a number of seats made of girth attached to a large rope. At the end of 2½ minutes they reach the first stage, and the other three stages are descended by wooden ladders, or by steps cut out of the salt. The guides point out as the greatest curiosity several small chapels formed out of the rock salt. One of these is 30 feet long, and 25 broad, and the altar, the crucifix, the ornaments of the church, and the statues of several saints, are all formed out of the salt. Several of the excavations are of an enormous size, and have their flat roofs supported either with beams of timber or pillars of salt. Guettard informs us, that the uppermost stratum is sand, the second clay occasionally mixed with sand and gravel, and containing marine petrifactions, the third calcareous stone, and the rest salt. These mines have been wrought for more than 600 years, and before the partition of Poland, the profits which belonged to the king amounted to L.97,222 sterling annually. These mines are excavated in a ridge of hills at the northern extremity of the chain which joins the Carpathian mountains.

The population of Cracow in the 14th and 15th centuries was about 80,000. In 1778, when Mr Coxe visited it, the town contained 16,000 inhabitants, but it appears from very recent accounts, that its population is now 24,000. East Long. 19° 56′ 0″, North Lat. 50° 3′ 52″. See Coxe's *Travels in Poland*, &c. vol. i. p. 124—153, 5th edit. *Briese uber Schlesien, Krakau, Wieliczka, im Jahr* 1791 von J. F. Zollner, Berlin, 1792, 8vo; and *Mem. Acad. Par.* 1762. (π)

CRAMBE, a genus of plants of the class Tetradynamia, and order Siliculosa. See BOTANY, p. 260.

CRAMP. See MEDICINE.

CRANE, in mechanics, is a most useful machine for raising and lowering heavy bodies and large weights, and removing them from one situation to another within the sweep of its arm, which revolves upon a center. Cranes are most commonly applied on quays and wharfs for loading and unloading vessels, also to ware-houses, and in the erection of massy buildings, such as bridges and locks, and to many other purposes. The parts of a crane are denominated the *post* or upright, which is either immovable or turns upon pivots, according to the construction; the *gib*, an arm extending from the upper part of the post; and the *stay*, which is intended as a support to the gib, and is fixed in a diagonal direction from the gib to the bottom of the post. These, with the mechanical combination of wheels, pulleys, and levers to give the requisite power for raising the weights, complete the crane.

The most simple form of the crane, is that commonly used in stone and timber wharfs for unloading ves-

Crane.

Simple windlass crane.

sels, for which purpose it is well adapted, its power being very great. It has a frame, consisting of a strong beam, supported horizontally at 10 or 12 feet from the ground, on the top of several vertical posts, very firmly fixed in the ground, and securely braced with stays in every direction. At the extremity of the horizontal beam, the upper pivot of the gib is supported, the lower pivot resting on a post in the ground. This gib, or gibbet as it is called, from a resemblance to that machine, is a triangular frame of wood, one side being perpendicular, and supported on pivots at the top and bottom, so that the whole moves round on those as a vertical axis of motion. Near the upper end of the perpendicular post, a beam proceeds, forming the upper side of the triangle; while the third side is a brace, extended from the foot of the perpendicular to support the upper piece. From the extremity of the latter, the burden is suspended by a rope passing over a pulley; the other end of the rope is coiled round a vertical roller or capstan, turning on pivots, one supported by the horizontal beam first mentioned, and the other on a post in the ground. The capstan is turned round by means of long horizontal levers fixed to it, at which a great number of men may be employed to push them round; or in some cases they are drawn by horses. As the levers admit of a very great length, in proportion to the diameter of the windlass on which the rope coils, the power of this simple crane is very considerable, and may be doubled by a pair of blocks or pullies at the gib. When the burden is raised to a sufficient height, by turning the capstan, the gib, being swung round on its pivots, will convey the load into a cart or waggon placed on shore by the side of the crane.

Walking wheel crane.

Another kind of crane, which is equally common with the above, but used for lighter burdens, has the same gib, as indeed most cranes have; but the windlass, or barrel for the rope, is placed horizontal, and has a large vertical wheel fixed upon it. This is made of two wheels fixed on the axis at a distance apart, and united by boards, so as to form a large hollow cylinder or drum. Several men get into this wheel, and by constantly walking upwards on the inside, give it a tendency to revolve, and wind up the rope on the barrel. See Carriage, vol. v. p. 546, and Plate CXXXI. It is surprising, that so imperfect a machine as this should have been so universally adopted as it was, till within these few years. Even when the wheel is sixteen feet diameter, the labourers within cannot walk so far up it, from the perpendicular, as to have any effective leverage to turn it round. Though they are always exposed to extreme danger, and frequently meet with most shocking and fatal accidents, from slipping down in the wheel, or from being overpowered by the load; in this case, the wheel runs back with an accelerating velocity, and the people are thrown about within it in a most dreadful manner. From these defects of the common construction, skilful mechanicians have devised cranes that are not only more safe, but more powerful in their operation than the common walking crane. Some of the best of these will be described in the present article.

Mr Padmore's addition.

Mr Padmore, many years ago, contrived to prevent the dangers attending the use of the construction last described, by putting a ring of cogs all round the outside of the great wheel, and applying a trundle provided with winches to turn it. By this addition, the power was increased in the proportion of the number of cogs in the wheel to the number of staves in the trundle; and in order to prevent the wheel from running back by the force of the weight, should the man within it slip, or leave off walking, he added a ratchet wheel to the axis of the trundle. Two winches being fixed to the ends of the axle of the trundle, gave the people attending the crane the means of assisting the men in the wheel, when the load rendered it necessary. On the axle of the trundle, he likewise fixed a wooden wheel, provided with a brake or gripe, which could be forcibly pressed on the circumference of the wheel by a lever, to cause such a friction as would prevent the weight from descending too rapidly. By this means heavy goods may be either raised or let down at pleasure, without any danger of injuring the men who work the crane. This contrivance is ingenious, but the rapid motion of the circumference of the large walking wheels, in most cases, renders it inapplicable, unless a smaller cog wheel was fixed upon the same axis with the walking wheel.

Mr Ferguson's crane.

A crane, to be turned by winches, was contrived by the late Mr Ferguson, which has three trundles with different numbers of staves. Any one of these may be applied to the cogs of a horizontal wheel, mounted on an upright axle, round which is coiled the rope for drawing up the weight. This wheel has 96 cogs; the largest trundle 24 staves, the next 12, and the smallest 6; so that the largest revolves four times for one revolution of the wheel, the next eight, and the smallest 16. The winch is occasionally fixed on the axis of either of these trundles for turning it, and is applied to one or the other, according as the weight to be raised is smaller or larger. There is also a fourth trundle acting in the teeth of the great wheel; and on its axis is a brake and ratchet wheel. While the load is drawing up, the teeth of the ratchet wheel slip round below a catch which falls into them, and prevents the crane from turning backwards; thus detaining the weight in any part of its ascent, if the man who works at the winch should accidentally quit his hold, or wish to rest himself before the weight is completely raised. Making a due allowance for friction, a man may raise, by such a crane, from three to twelve times as much in weight as would balance his effort at the winch, viz. from 90 to 360lbs. taking the average labour. See Ferguson's *Lectures*, vol. ii.

Crane with cog wheels.

Many other constructions of wheel-work are in common use for cranes. When they are turned by a winch, it is proper to apply a fly wheel to the axis of it, both to equalize the efforts of the labourer who turns it, and in case he accidentally lets go the handle, to prevent the load from running down so quickly as to endanger any thing. It is convenient to have several different powers to a crane of this kind, to adapt it for the different burdens to be raised. This is best done by employing a train of several wheels, each turned by a pinion smaller than itself. Thus, suppose the barrel on which the rope or chain winds be 12 inches diameter, and has a cog wheel of 96 teeth fixed upon the end of it, this is turned by a pinion of 12 leaves; on the same axis with this is a wheel of 32 teeth, moved by a pinion of eight, situated on a third axis, which should carry the fly wheel. A winch of one foot radius can be applied to any of these three axes in the crane, and will give three different powers. Thus, if it is applied to the gudgeon of the barrel, it will double the power of the labourer, because the winch describes a circle which is twice as large as the barrel on which the chain winds. If the winch is fixed on the end of the axis which carries the pinion of 12, and wheel of 32, it will give the labourer a purchase of 16 times. And lastly, when the

Of three powers.

winch is applied to the pinion of eight, his efforts will be multiplied 64 times. This simple mechanism is rendered very complete, by fixing a fly wheel upon the axis of the pinion of eight, to prevent all danger of accidents; for which purpose it is more effective than a ratchet wheel, and requires no attention. The spindles of all the wheels are made capable of sliding endwise, for the purpose of disengaging the wheels from each other at pleasure, that when the wheels are not employed there may be no unnecessary friction in turning them round.

Mr White's inclined walking wheel.

Plate CCXV. Fig. 4.

To remedy the inconveniences and defects of the common walking-wheel crane, Mr James White, of Chevening in Kent, proposed the construction shewn in Fig. 4. which is described in the Transactions to the Society for the Encouragement of Arts. BB is an inclined axis or spindle, turning on pivots at c and b, which are supported in the different floors of the warehouse where the crane is erected: on this axis the rope of the crane is coiled, and, passing over a pulley at D, is conducted to the gib. The motion is given by people walking on an inclined wheel AA, which is strongly framed upon the axis, and revolves with it: it is inclined to the horizon about 20 degrees, and works in an opening in the floor $m\,m$. Now, it is plain that a man walking upon this wheel will, by his weight, give it a tendency to revolve, and the power will depend upon his distance from the centre of the wheel; but to increase his effort beyond his mere weight, he applies his hands to a rail F, extended across the wheel about breast high, and pushes the wheel round beneath his feet. By this combined action of his weight and muscular action, the inventor supposes a labourer will work to a greater effect than in any other manner. To render it quite safe from accidents, a brake is thus applied: the rail F is fixed at one end to an upright axis EG, so that it acts in the manner of a lever; G is a shorter lever fixed on the same axis, and connected by an iron rod H, with a gripe K, which embraces part of the circumference of the wheel, to prevent its turning unless the brake is first removed by pushing the rail F; g is a chord fastened to the extremity of the rail F, and, going over a pulley in the floor, has a weight suspended from it. This always gives the rail a tendency to draw the gripe close, and stop the wheel; and by the weight coming up to the pulley, it stops the rail from going too far, when pressed by a man walking on the wheel. The stationary end of the gripe is jointed to a stout upright beam, going from the floor to the ceiling; and to prevent the gripe falling down, and getting from its work, the intermediate part of it is suspended by cords from the ceiling. The safety of this crane is its greatest recommendation; for it is obvious that it cannot move but during the pleasure of the workman, and while he is actually pressing upon the rail F; and if he should slip down, or the crane rope break, the gripe stops the wheel the instant he ceases to press on the rail. Mr White's crane admits of an almost infinite variety of

Its powers.

different powers within its limits; and this variation is obtained, without the least alteration of any part of the machine; if, in unloading a vessel, there should be found goods of every weight, from a few hundreds to a ton and upwards, the man who does the work will be able so to adapt his strength to each, as to raise it in a space of time proportional to its weight, he walking always with the same velocity, as nature will teach him. It is a great disadvantage in some cranes, that the smallest weight must be as long in raising as the largest, unless the man turns or walks with a greater velocity, which tires him in still greater proportion. In some cranes, two or three different powers may be procured, to obtain which some pinion must be shifted, or a fresh handle applied and resorted to. In this crane, on the contrary, if the labourer finds his load so heavy, as to permit him to ascend the wheel without its turning, let him move only a step or two towards the circumference, and he will be fully equal to the task. Again, if the load be so light, as scarcely to resist the action of his feet, and thus oblige him to run through so much space, as to tire him beyond necessity, let him move laterally towards the centre, and he will soon feel the place where his strength will suffer the least fatigue by raising the load in question.

Crane gibs.

The gibbet of a crane is a very principal member, as we have before explained; but, in its common construction, it has some defects. The rope by which the burden is raised, passes exactly over the upper gudgeon of the vertical beam of the gib, and is confined between two small vertical rollers, in order that it may constantly lead fair with the pulley or sheave at the extremity of the gib. According to this construction, whenever the gib turns round its axis, the rope is bent so as to form an angle more or less acute, which causes a great increase of friction, and produces a continual effort to bring the arm of the gib into a parallel position to the inner part of the rope. These inconveniences may appear to be trifling, but, in actual practice, they are of no small importance; for they necessarily require a much greater exertion of power in raising goods, and the application of a constant force to keep the gib in the position that may be requisite; while the partial stress which is exerted on only a few strands of the rope, whilst bent into an acute angle, destroys it in a very short time.

Mr Bramah's gib.

A simple construction of the gib, invented by Mr Bramah, obviates all these defects, and at the same time possesses the very desirable property of permitting the gib of what is termed a wharf, or landing crane, to revolve wholly round its axis, and to land goods at any point of the circle described by the arm of the gib.

Plate CCXV. Fig. 1.

The simplest form of this contrivance is shewn in Fig. 1. in which AA represents the gib of a warehouse crane projecting from a wall. It has, as usual, a pulley at the extremity, from which the goods are suspended. The improvement consists in placing a pulley at S, to conduct the rope down through the axis of motion of the gib, the collars or rings, $a\,a$, on which it swings, being perforated for that purpose. The rope afterwards passes under a pulley b, which conducts it into the house to the crane or machine, by which the weight is elevated. The pulley b may be placed between the two collars $a\,a$, and then there will be no necessity for a perforation of the lower pivot of the gib. When the gib is required to describe a complete circle, instead of the two brackets at $a\,a$, fixed to the wall, a cast-iron pillar is used to support the gib, the collars $a\,a$ fitting upon it. The pillar is hollow, to admit the rope through it, and is firmly fixed in a vertical position, by a plate cast on the lower end of it, and screwed down upon the timber of the wharf. Beneath these beams there is another pulley, in place of b, to conduct the rope to the crane.

In many cranes, the whole machinery turns round together upon the pivots of the gib, which method answers extremely well, as it simplifies the machine, takes up less room, and admits of its reaching all round in a

3

Crane.

Mr Gilpin's crane. Plate CCXV. Fig. 5.

circle. Plate CCXV. contains two of the best constructions on this principle. Fig. 5. is one invented by Mr Gilbert Gilpin, who presented it to the Society of Arts. It is particularly adapted for the use of a foundry, where heavy articles are required to be lifted in every part of the circle that the crane describes. The whole machine consists of a gib, the wheel-work being attached to it. The perpendicular, AB, is formed of two oak planks, only one of which can be seen in the Figure; they are eighteen inches wide, four thick, and sixteen feet long. These, at the top and bottom, are let into cast-iron mortise pieces CD, which retain the planks at ten inches asunder. E is the barrel for the chain, which has a spiral groove turned in its circumference, for the reception of the links of the chain: it turns in the space between the two uprights AB. The top mortise piece C, as shewn by the dotted lines, has in the middle a dovetailed mortise, into which the stock H for the gib is fixed, and three bolts shewn at *k* secure the planks H fast to the uprights. These planks are of the same dimensions as the uprights, and the space between them forms a groove or opening for the top block K to slide in. The block is made of cast-iron, and has two grooves, which slide upon the upper edge of the planks H, only one of which is seen in the Figure. The block K carries the pulley *m*, over which the chain passes. The diagonal stay M is formed in a similar manner, and of the same dimensions as the other parts of the gib: it is connected to the perpendicular, by being received into the lower mortise piece D. N is the handle or winch to work the crane; it has a small pinion O fixed on the same axis: this pinion works in the teeth of the wheel P, on the same axle as the chain barrel E. S is the running block and hook, by which the goods are raised. Fig. 6. is an edge view of the lower part of the perpendicular, shewing the handle N, the pinion O, the great wheel P, and the barrel E, placed betwixt the two uprights AB. The whole of this crane is moveable on the pivots of the gib, the lower one of which is supported on the groundsil R, and the other by a beam F, extended across the building in which it is placed, so that the gib has liberty of traversing all round, to take up a burden at any part. The block K also slides along the upper beam H of the gib, and can be fixed at any place, which admits of the block S being brought perpendicularly over any spot. This is of very great importance in an iron foundry, for lifting heavy castings, cannon, &c. out of the moulds. We have seen one of these, in which the sliding block K had a long toothed rack attached to it. This was worked by a pinion, the axis of which carried a pulley for the reception of an endless rope, hanging down in reach of the workmen, who could therefore, by means of it, turn the pinion, and move the rack with the block to the desired spot, so as to give the crane any range within its reach; and it would take up a weight as well at six feet from the centre as at ten, which rendered it a most useful implement in such a situation, where the crane is frequently used to lower down moulds upon one another in a perpendicular direction. Mr Gilpin's crane shews a very good mode of construction for the gib, scarcely any part of the timber being cut away, and the strength of the materials, so far from being diminished, is augmented by the cast-iron mortise pieces. The upper beam of the gib is brought much closer to the upper gudgeon, and the centre lines of the perpendicular and the diagonal stay crossing each other at the top of the lower mortise piece, places the whole strain as near as possible in a line with the gudgeons. The business of the perpendicular becomes in consequence little more than that of a mere prop, and consequently requires no greater strength of materials than the diagonal stay. The barrel E, for the chain, is, as before mentioned, formed with a spiral groove, for the reception of the lower halves of those links which stand upright, the intermediate links lying flat on the surface of the barrel, as is shewn on a cross section, Fig. 7. By this means the chain leads extremely fair, and will work with far less friction than ropes, or any other contrivance. The pulleys S and K are grooved in the same manner. Fig. 8. by way of contrast, shews the awkward manner in which the links of a similar chain arrange themselves on a common pulley, tending to rend open the links as much as to resist the strain. This method of reeving chains, and substituting them for ropes, has, within these few years, become very general, as well in cranes as in the engines for drawing coals out of mines. It was, we believe, first adopted by the ingenious Mr Smeaton, in a crane he erected at the custom-house, about thirty years ago.

Fig. 6.

Crane.

Chain barrel.

Plate CCXV. Fig. 7.

Fig. 8.

Mr Kier's moveable crane. Fig. 9.

Fig. 9. represents a crane mounted on four trucks, to be capable of removal from place to place. It is employed on Ramsgate pier, for lifting stones used in the building, and is extremely well adapted for such a situation, as it requires no fixture, and will take up a weight of 4 tons with four men, without any danger of upsetting, which is a sufficient power for such purposes. It was designed and executed by Mr Peter Kier, by order of the trustees for the management of the harbour at Ramsgate. Its base consists of a cast iron frame marked AB, 9 feet 7 inches square, and two tons weight, supported on four cast iron wheels *b*, *b*, one pair of which is fixed on a common axle, which moves round on a centre fixed to one side of the frame. This axle has an arm projecting across beneath the frame to the opposite side, where a rack, or segment of a wheel, is fixed on it, as shewn at *c*, engaging a pinion *r*, shewn before the rack, on the top of whose axis a winch is applied at *d*. Now by turning this pinion, it twists the wheels round upon their centre, to steer the crane when moving from place to place. A vertical cast iron shaft DF, weighing 23 cwt. is erected on the centre of the iron frame, and is supported by oak braces E, E, stepped into boxes cast out of the iron frame AB at its angles, so as to form a very strong perpendicular column, round which axis the whole crane traverses. The weight of the framing and wheelwork, is supported by a steel pivot or gudgeon on the top of the shaft at F, and is guided by a collar embracing the shaft at I. The framing of the gib, or moveable part of the crane, consists of a long beam GH, bearing the pulley G at the extremity, resting on the pivot of the upright pillar in the middle, and the other end supporting the frame for the wheelwork LMN. Into this beam are framed two uprights Q, Q, suspending the platform IK, on which the men who work the crane stand. It is braced by a diagonal stay IP, and a cross piece R to prevent its bending.

Bramah's hydrostatic crane.

Mr Bramah's ingenious hydrostatic principle of gaining a great power, is applicable in several ways to the raising of heavy weights, and has been frequently employed in powerful cranes. In these, the power is not obtained by wheelwork, pulleys, or any other of the ordinary mechanical powers, but on the principle of the experiment called the hydrostatic paradox, which has been known for ages; but the application of its powers to useful purposes is due to Mr Bramah.

The simplest form is, for a machine to raise a heavy

Bramah's hydrostatic crane.

weight to a small height. A metallic cylinder sufficiently strong, and bored truly cylindrical within, has a solid piston fitted into it, which is made perfectly water tight, by leather packing round its edge, or other means used in hydraulic engines. The bottom of the cylinder must be made sufficiently strong with the other parts of the surface, to resist the greatest strain which can ever be applied to it. In the bottom of the cylinder is inserted the end of a small tube, the aperture of which communicates with the inside of the cylinder, and introduces water or other fluids into it. The other end of the pipe communicates with a small forcing pump, by which the water can be injected into the cylinder beneath its piston. The pump has of course, valves to prevent the return of the water. Now suppose the diameter of the cylinder to be six inches, and the diameter of the piston of the small pump, or injector, only one quarter of an inch; the proportions between the two surfaces, or ends of the said pistons, will be as the squares of their diameters, which are as 1 to 24. Therefore the areas will be as 1 to 576; and supposing the intermediate space between them to be filled with water, or any other dense and incompressible fluid, any force applied to the small piston will operate on the other in the above proportion of 1 to 576. Suppose the small piston, or injector, to be forced down when in the act of forcing, or injecting with a weight of 20 cwt. which can easily be done by means of a long lever, the piston of the great cylinder would then be moved up with a force equal to 1 ton multiplied by 576. Thus is constructed a hydro-mechanical engine, whereby a weight amounting to 576 tons can be raised by a simple lever, in much less time through equal space than could be done by any apparatus constructed on other known principles of mechanics, because it has so little loss from friction; and it may be proper to observe, that the effect of all other mechanical combinations is counteracted by an accumulated complication of parts, which renders them incapable of being usefully extended beyond a certain degree; but in machines, acted upon or constructed on this principle, every difficulty of the kind is obviated, and their power is subject to no finite restraint. To prove this, it will be only necessary to remark, that the force of any machine acting upon this principle, can be increased *ad infinitum*, either by extending the proportion between the diameter of the injector and the great cylinder, or by applying greater power to the lever actuating the small pump.

Plate CCXV. Fig. 1.

Fig. 1. Plate CCXV. represents a crane constructed on the hydrostatic principle, that is, by the injection of water from a small pump into a large cylinder, which is fitted with a piston, having a rack attached to it for the purpose of turning a pinion upon the axis of a large drum wheel or barrel, round which the rope is coiled, and from thence passes to the gib. In the Figure, AA represents the gib made of iron, and supported upon two brackets *a*, *a*, projecting from the wall of the warehouse in which the crane is supposed to be erected. The rope passes over the pulley S, and down through holes in the brackets *a*, *a*, then turns under the pulley *b*, and comes to the lower side of the great drum wheel B. The pinion C is fixed on the same axis with this, and its gudgeons turn in small iron frames *d*, bolted down to the floor of the warehouse. The pinion *c* is actuated by the teeth of the rack D, and a small roller, whose pivot is shewn at *e*, presses against the back of the rack, to keep its teeth up to the pinion. The rack is attached to the piston D of the cylinder L, in which the power for working the crane is obtained. This piston passes through a tight collar of leather in the top of the cylinder at E, which does not admit of any leakage by the side of it, and therefore if any water is forced into the cylinder, it must protrude the piston from it. The cylinder is supported in a wooden frame FF, and has a small copper pipe *g g* proceeding from the lower end of it, communicating with a small forcing pump at *h*. This stands in an iron cistern H, which contains the water, and sustains the standard *ii* for the centre of the handle G, with which the pump is worked by one or two men. The upper extremity of the standard *ii*, guides the piston rod *k* of the pump, to confine it to a vertical motion. *l* is a weight for counterbalancing the handle G of the pump. From what we have said before, the operation of this machine is evident. The power of the cylinder D is, in proportion to its size, compared with the size of the pump; but as it acts only through short limits, the pinion and drum B are necessary to lift the weight a sufficient height. The operation of lowering goods by this crane is extremely simple, as it is only necessary to open a cock at *m*, which suffers the water to escape from the cylinder into the cistern H, and the weight descends, but under the most perfect command of the person who regulates the opening of the cock; for, by diminishing the aperture, he can increase the resistance at pleasure, or stop it altogether.

Another kind.

Plate CCXV. Fig. 2.

Fig. 2. is the section of a cylinder for a crane, which is only adapted to raise weights to a small height, but possesses a great power; O is the chain, which is conducted over pulleys to the gib; CC is the cylinder, having a lid screwed on the end, with a stuffing box *m* in the centre, which makes a close fitting round the rod *l l*; this, at the other end, has a piston *k* fixed on it, which accurately fills the cylinder, and has leather all round to make it water tight. The other extremity of the cylinder has an eye cast on it for the reception of a hook, by which the cylinder is made fast. The pipe from the injecting pump is marked *i*. This cylinder may be placed horizontally beneath the floor, or suspended vertically by the side of the wall, and forms a most excellent and convenient crane for lifts of not more than 6 or 8 feet, though it may occasionally be used for a much greater height. Thus the rod *l* terminates in a large eye, through which the chain O is conducted; and a peg or pin being put through one of the links, gives a hold on the chain to draw up the weight, which being raised till the piston *k* reaches the bottom of the cylinder, the chain is to be made fast by a pin put through the links, and stopped against any fixture; the piston rod drawn out, and a new part of the chain taken through the eye at the end of it, to take a second lift; and so on of a third if required.

Application of the hydrostatic crane

The greatest advantage of the hydrostatic principle, is, that its power can so easily be transmitted to any distance, and in any direction, by means of pipes, conducted along in situations where all other means of conveying the motion would be complicated and expensive in the extreme; thus, in an extensive range of warehouses for a dock or depot, an injecting pump may be kept in constant action by horses, a water-mill, or steam-engine, and may inject water into an air vessel, from which pipes are conducted to cranes in all parts of the works; and by simply opening a cock at any crane, the required load will be instantly raised by the elasticity of the confined air operating on the enlarged surface of the piston of the crane. The air vessel has of course a safety valve, to allow the escape of the water when the pressure becomes so great as to endanger the rupture of the vessels; for it is to be observed, that the power of this principle is irresistible when the

Crane.

pump is worked by a mill, and will burst any vessels without the appearance of strain on the moving parts of the pump.

With an air vessel. Plate CCXV. Fig. 2.

The construction of a pump and air vessel of this kind is explained in Fig. 2. A represents the piston of the pump moving in a tight collar of leather at *a*, and is worked from the beam of a steam-engine, or other convenient power; *b* the suction valve of the pump, and *e* the forcing valve; *d* a small copper pipe communicating from the pump to the air vessel BB, and conducting the water into it; *l i* is one of the pipes proceeding from the air vessel to one of the cranes, and may be of any length, according to the distance of the crane. Near the cylinder of the crane, which may be either like Fig. 1. or Fig. 2. the pipe is provided with a stop valve *e*, formed on the end of the screw *g*, by turning which the valve can be opened or shut to admit the confined water from the air vessel into the cylinder, and thus raise the weight required: *h* is a similar valve, for lowering the weight, by permitting the discharge of the water at the opening *t*; for it is plain, that by shutting the valve *e*, and opening the discharge valve *h*, the water will return from the large cylinder of the crane along the pipe *i*, and rush out at the aperture *t*, and by that means permit the descent of the weight. On the other hand by keeping the discharge valve *h* shut, and opening the other at *e*, the water will have free passage from the air vessel to the great cylinder, which has been before described. The air vessel in this crane being charged with a great pressure by the pump, becomes a common reservoir for the supply of any number of cranes; and by opening the valve *e*, the water enters the great cylinder, and takes the weight up at once without loss of time. A safety valve, such as that shewn in Fig. 3. must be placed in some convenient part of the pipe *d*, to prevent the air vessel from being burst by overstraining it.

Lowering apparatus by Mr Hardie.

The common method of lowering goods, in wheel-cranes, by a brake and wheel, even with the advantage of a counterweight, is liable to injurious accidents to the men, as well as the goods, when they consist of damageable articles, such as wine, spirits, glass, &c. and sometimes from the rapid motion of the crane, parts of it fly off with violence, killing or wounding the persons near it; at other times the brake-rope becomes entangled by turning off the pullies or otherwise, or the rope may slide out of the hand of the man who conducts it; in either of which cases, the goods descend with all the accelerated velocity of a falling body, receiving damage, and killing or hurting the men, horses, &c. which happen to be beneath them; but these evils are completely removed by a lowering cylinder invented by Mr Hardie, and explained in Figs. 10. and 11. AA is a cast iron cylinder, bored true within, and screwed down to the iron bottom BB; by the side of this cylinder a pipe C is cast, communicating with it at the top and bottom at *c d*; the pipe C has a cock D in the middle, shutting off, at pleasure, the communication between the top and bottom of the cylinder A A; the spindle of this cock passes through a stuffing-box at *a*, and has a rack or sector *b*, fitted on it, to confine the cock in any position by the claw *e*, which drops into the teeth of the sector, at the same time showing the extent of the apertures which is opened. The large cylinder AA, has a tight piston E, sliding up and down in it, and its rod F slides through a stuffing box G, packed with leather to prevent leakage; the connecting rod H is jointed to the piston rod, at bottom, and to the crank I at the upper end. This crank is formed on the axis of the chain barrel, or any other convenient spindle of the crane, so that the burden cannot descend without turning the crank, and giving the piston a reciprocating motion up and down in the cylinder.

Plate CCXV. Figs. 10, 11.

Operation. Plate CCXV. Figs. 10, 11.

To explain the operation of this cylinder, suppose the piston pushed down to the bottom, and the cock D opened, it must be filled with oil, water, or any other liquid not likely to freeze or change by the weather, and the lid of the cylinder screwed fast down. Now, if the cock is quite shut, the oil or other liquid confined between the bottom and top of the cylinder, and the piston, will prevent it from moving, consequently the crank I, and chain barrel, or other part of the crane connected with the crank, stand at rest, suspending the weight of the goods hanging from the crane; but if the cock is opened a very little, the oil passes slowly through its aperture, and allows the piston E to move up and down slowly, and compelling the crane to move so too, regulates the descent of the goods. Thus the cock, by being more or less opened, regulates the precise velocity of the crane, or descent of the goods to be lowered, whatever their weight may be. (J. F.)

Cast iron cranes.

Cranes have been generally constructed of timber, but cast and wrought iron have been lately introduced, and, we think, with advantage, as they are generally exposed to the variations of the weather, which must soon injure the mortises and joinings of a wooden crane; besides, cast iron offers all the advantages of a judicious combination of its parts in having the strength duly proportioned, and in adapting its formation to any situation or circumstances.

Plate CCXVI. Fig. 1.

Plate CCXVI. Fig. 1. is a small cast iron crane: the post is made to turn in a collar fixed level with the ground's surface, and the bottom part is fixed on a wall or an iron cylinder. The gib and stay are in one casting, and joined to the post by screw bolts. This crane will carry one ton weight with safety. Fig. 2. is a similar crane, of greater strength and power. The collar is here drawn to revolve on a number of balls to lessen friction, but we think this unnecessary. It has a double gib and stay, which screw on each side of the post, and admit the pulley between them. The thickness of the plates of the gib may be $1\frac{1}{4}$ inch each, and will carry three tons with safety at the extremity of the gib. Fig. 3. and 4. are side and front elevations of a crane; the post is immoveable, and is fixed on an iron frame with arms extending in the form of a cross; the extremities of which are bolted down by strong screws to large blocks of stone sufficiently heavy to more than counterpoise the weight to be raised by the crane. In the top of the post is fixed a wrought iron pivot, by which the weight is supported, and a strong cast iron cap bears on the pivot, and has attached to it two iron frames, one on each side, that receive the pressure from the stay, as well as support the pull of the gib, which is formed of two bars of wrought iron. The lateral pressure is borne by the bottom of the post, round which two friction rollers turn to facilitate its motion. The Figures will sufficiently shew the construction of its parts. This crane will carry five tons with safety. Fig. 5. is another crane nearly similar to the last in construction, but the gib and stay are of cast iron in one piece or frame, two of which are used, (one on each side of the post,) and are supported by the cross cap at top and friction rollers at bottom. Here the wheel work is supported between the frames, which extend sufficiently wide to-

Fig. 2. Figs. 3, 4. Fig. 5.

wards the post to leave space for the barrel, and are brought so nearly together at the extremity to admit only the pulley between them. Chains are generally used to cranes exposed to the weather; and it is a considerable improvement to the barrels on which they wind, to have a spiral groove or hollow to receive them, as it prevents snapping and jerks from the climbing of the chain. This crane, with the frames $1\frac{1}{2}$ inch thick, will lift five tons with safety.

Plate CCXVI. Fig. 6.

Fig. 6. is a crane suitable for an iron foundry, the top pivot being supported by the roof: it is here introduced to show one of the methods of moving the pulley block, so useful in many cases. The gib is formed by two iron plates, between which the pulley block slides, being supported by the top edges of the gibs; to the pulley block is attached a moveable rack into which a pinion works; on the same axis with the pinion is fixed a larger wheel, into which another pinion works to give power to slide the block when a considerable weight is appended. These are turned by pulling a chain which works into an angular groove of a wheel placed on the same axis with the latter pinion. The plan will show the other parts of the crane, which will raise a weight of ten tons with safety; the plates of the gibs being two inches thick.

Fig. 7.

Fig. 7. is a barrel fixed between two iron frames, and a wheel and pinion to increase the power of a man at the winch: this is called a crab, and is most useful as a portable machine where mechanical power is required.

For the drawings and descriptions of these cast iron cranes, the Editor has been indebted to Mr Jessop, junior.

Plate CCXVII. Figs. 1, 2.

Figs. 1. and 2. are a side and back view of a pit crane erected in Messrs Sargent and Rutty's wharf, on the Grand Junction Canal at Paddington. It is composed of a cast iron frame shaft, with an oak gib and brace. It has three different powers, and each power is a double purchase. The height of the shaft is 20 feet, of which 11 feet is below the surface of the ground; it rests on a gudgeon about 6 inches diameter, and turns in a brass pot. At the surface of the ground two plates are fixed to the shaft about $4\frac{1}{2}$ inches asunder, between which are five rollers; when the crane is turned, these rollers move round the inside of a cast iron ring, which is fixed to timbers secured on the top of the wall of the pit; the disposition of these rollers will be seen in Fig. 3. The ends of the gib and brace are received into sockets cast in the shaft, and secured there by wrought iron straps. The gib is about 21 feet long, 12 inches by $10\frac{1}{2}$ at the shaft, and 16 inches by 12 at the outer end; the brace 10 inches square. The frame which composes the shaft is three inches in thickness; 1 foot 4 inches in breadth at the surface of the ground, and diminishes to 6 inches in breadth at the top, and to about seven inches at the bottom.

The diameters of the wheels and pinions are taken at the pitch line.

This crane was made by Messrs Lloyd and Ostell, London, and is warranted by them to carry eight tons with safety. It has occasionally been loaded with ten tons without appearing in the least strained. It cost, (1813,) including brickwork, timber, and fixing, L.350.

Plate CCXVII. Fig. 4—8.

The remaining Figures of Plate CCXVII. represent the double crane now in use (1813) for constructing the breakwater for protecting the entrance to Aberdeen harbour.

Fig. 4. represents a transverse view of the crane, working gear, and rollers for moving the crane forwards.

Fig. 5. is a longitudinal view of the crane and part of the breakwater, with one gib laying a stone on the building, and another lifting a stone from the waggon, which, with the railway, comes under the crane.

Fig. 6. exhibits a plan of the crane, with waggons and railways, as they are laid on when the work advances.

Fig. 7. shews an enlarged side view of the sliding carriage at *m* and *n*, Fig. 5, for laying the stones either close to the shaft, or as far out as the gib will reach. It is worked by a sheave and rope passing over the point of the gib, and down by the side of the spindle.

Fig. 8. is a plan of the sliding carriage and the sheave, over which the principal working chain or rope passes, and is attached to the working gear, which is placed in the middle to save room.

For the drawings and description of this crane, the Editor is indebted to Mr Gibbs, who superintends the improvements of the harbour at Aberdeen.

The cranes used for building the locks, &c. on the Caledonian canal, have a shaft about 40 feet high and one foot square; they turn upon a gudgeon at the bottom. At the top is a similar gudgeon, and a plate with four arms, and a hole in the centre is dropped upon it; to each of these arms is fixed a guy rope, which is carried to such a distance from the shaft, that when the crane turns round, the gib may keep clear of it. The lower end is thus connected with a pair of pulley blocks previously fastened to a pile driven in the ground for that purpose, and then drawn tight and secured. The gib is 26 feet long and 10 inches square, fixed a little higher than the middle of the shaft, supported from below by a brace, and suspended from above by a wrought iron bolt one inch square. It is worked by a common wheel and pinion.

It is advisable that the axis of the winch should be three feet from the surface of the ground, this being the height at which a man can most conveniently work it; its radius should be 1 foot 6 inches, which is as large as an ordinary man can conveniently turn, and by making it less, power is lost.

intellectual powers. See CRANIOMETRY, CRANIOSCOPY, and CRANIUM.

CRANIOMETRY, (from κρανιον, *the skull,* and μετρέω, *to measure,*) the art of measuring the skulls of animals, so as to discover their specific differences. It is of late only that this subject, which opens an important and most interesting field of investigation, has been examined with that attention which it deserves. The first attempt at any general remarks on the subject is contained in a paper entitled, "*Sur la difference du grand trou occipital dans l'homme et les autres animaux,*" by Daubenton, in the Memoirs of the French Academy of Sciences, for 1764. In this paper he endeavours to point out the differences existing between man and other animals, without any definition of the characters separating the races of mankind from one another; and nothing farther was done until the time of Camper, who, in 1791, attempted a more systematic arrangement of the national forms of the cranium; but unfortunately he did not possess a sufficient collection of skulls for this purpose. The differences he has pointed out regarding the degrees of prominence of the jaws, therefore, afford very insufficient criteria for determining the numerous points of distinction which characterise the *crania* of different nations.

It is very obvious, that a very close connection exists between the bones of the skull, and the features, or external parts of the face which they support; therefore a careful examination of the crania of the different species, will throw considerable light on the subject of varieties of the human race; for when freed of their soft parts, which are inconstant and less regular in their formation, they exhibit the firm and solid foundation of the head, they can be conveniently handled and examined, considered in various points of view, and compared with one another. Such a comparison shews us that the different races are no less distinguished by form of head, than by colour and features. Hence anatomists and naturalists have attempted to lay down some scale of dimensions to which the various forms of the skull might be referred, and by means of which they might be reduced into certain classes: how far they have succeeded, we shall endeavour to point out. Of these, the *Facial Line* or *Angle* of Camper first claims our attention.

FACIAL LINE OF CAMPER.

Facial line of Camper.

The cranium being placed laterad, two imaginary lines are drawn on its surface to meet each other at a particular point. The one proceeds horizontally through the meatus auditorius externus and the floor of the nostrils; the other from the most prominent portion of the forehead above the nose, to the front of the alveolar margin of the upper jaw-bone. The angle formed by the junction of these two lines is termed *Camper's facial angle,* which this illustrious anatomist conceived would point out the specific differences in the crania of men and other animals. By this measurement,

The angle of the European forms an angle of . .	80°
of the negro, ...	70
of the orang-outang, ...	58
of some monkeys, ...	42
of some mammalia, only	20

The boundaries of the facial line in the genus HOMO, are 70° and 80°; a smaller angle than the former constitutes an approach to the monkey. It may, however, be extended far beyond the latter, and still have a pleasing, nay fine effect. Thus in the Grecian statues we find the angle 100°; when beyond this the face appears monstrous; when below 70°, it is that of a brute.

This criterion of Camper's, is subject to some very essential objections. It is sufficiently obvious, that this line is only applicable to such varieties of the human race, as differ from each other in the various degrees of prominence of the jaws; and that it will not at all exhibit the characters of those which vary in the opposite way, viz. the greater or less breadth of the face and cranium. For it frequently happens, that crania of the most distinct nations, which differ *toto cœlo* from each other on the whole, have the same facial angle; and on the contrary, that skulls of the same nation, which agree in general character, differ very much in the direction of this line. Thus in the *Decades of Blumenbach,* we have represented the crania of a Negro and of a Pole, in whom the facial angle is exactly the same; and yet the general characters of the two skulls are widely different. In the former, the skull is narrow and almost keel-shaped; in the latter, broad and square. In the same work, two negroes skulls of very different facial angles, when viewed in front, most incontestibly betray their Ethiopic origin, by the same characters of a narrow and compressed cranium, and arched forehead. Camper himself, too, has employed his two lines, in the plates subjoined to his work, in so arbitrary and inconstant a manner, changing frequently the point of contact, on which their whole utility must depend, that he clearly appears to be hesitating and uncertain in their employment. This is not all; did Camper foresee that this line might change its position while the form of the head continued the same? "In the young skeleton," (says the celebrated anatomist Dr Barclay, in his *Anatomical Nomenclature,* page 150.) "where the bony meatus is entirely wanting, and where the line must consequently be drawn from the middle of the ring to which the membrana tympani is attached, will its direction be found the same, with regard to the face, as in the adult? Certainly not. The membrana tympani, or bottom of the external meatus, is more forward, inward, and downward, than the orifice where it is joined to the concha; and therefore the direction of this line, with regard to the head, must vary with the changes and relative situation of the meatus; a situation which is known to be different in different animals. In the cat, for instance, it enters horizontally; is more basilad than the zygomatic arch; and its basilar margin is more basilar than the base itself, or advances farther in the basilar direction. In the babyroussa, the meatus is long; runs from the tympanum in the coronal, lateral, and inial directions; or rises upwards, outwards, and backwards, supposing the erect posture of the animal, and the base of the head, to be at right angles to the vertebral column. In this animal, the external orifice of the meatus is more coronal than the zygoma, or more towards the crown of the head. If in these two instances, therefore, we were, in the manner of Camper, to draw the horizontal line from the middle of the orifice of the meatus, we should draw it from different points of the head, or from points that do not correspond in relative situation. The other point to which it is drawn is likewise variable with respect to position. In man and quadrupeds it is found near the maxillary curve. In birds it is often at one extremity of the maxilla, sometimes in the middle. In cetaceous animals, the spirucula, or breathing holes, run in a direction obliquely from the base towards the corona, and terminate in the face near the glabellar part of the cranium." The angle would, in such cases, be larger than

Craniometry.

human, approaching nearer to the Grecian divinities. To obviate this in some degree, Dr Barclay, and at the same time Cuvier, proposed two lines, which we shall call

Dr Barclay's Basi-facial Lines.

Dr Barclay's basi-facial lines.

The first, or *superior basi-facial angle*, is formed by drawing a line along the basilar surface of the palatine process of the superior maxillary bone, to meet the facial line; where this line is interrupted by the alveolar process, a line may be drawn from the dermal side, on the supposed continuation of the palatine plane. When the palatine plate is concave or convex, the line is supposed to be drawn on a plane that passes through its inial and antinial extremities. To measure this angle, an instrument, termed a *Gonio-craniometer*, has been invented by Dr Leach, Plate CCXVIII. Fig. 7, of which an explanation is given at the end of this article.

The second, or *inferior basi-facial angle*, is formed by drawing a line along the base of the lower jaw, until it meets the facial line. If the basilar side be either concave or convex, it is supposed to be drawn on a plane that proceeds from the angles to the basilar or lower side of the curvature. There is still another method of measuring, or rather viewing, the skull, which is termed

The Norma Verticalis of Blumenbach.

The Norma verticalis of Blumenbach.

Blumenbach states, that in the examination and classification of his immense collection of the crania of different nations, he finds it every day more and more difficult, amidst such numerous differences in the proportion and direction of various parts, all of which contribute more or less to national character, to reduce these to the measurements or angles of any single scale. Since, however, in distinguishing the characters of different crania, such a view will gain the preference over all others, as offers at one glance the most numerous and important points, and such as contribute especially to the comparison of national characteristics; he has found, from experience, that to be the best adapted to this purpose, which is obtained by placing the different crania, (including the lower jaws, if possible) with the zygomas, in the same perpendicular line, on a table in a row, and contemplating them from behind. When crania are thus arranged, those circumstances which contribute most to the formation of the national character, the direction of the jaws and cheek-bones, the proportional breadth or narrowness of the head, the arched or flattened form of the glabella, are all distinctly seen at one glance. This method of considering the cranium, is called by Blumenbach *Norma verticalis*. It is shewn in Plate CCXVIII. Figs. 3, 4, 5. Fig. 3. the skull of a negress from the coast of Guinea; Fig. 4, of a Georgian female, distinguished by the symmetry and beauty of all its parts. It is in the collection of Professor Blumenbach, from whose work the annexed outline is taken. The form of this head is of such distinguished elegance, that it attracts the attention of all who visit the collection in which it is contained. It corresponds exactly with the marble statue of a nymph in the collection of the late Mr Townley, of which Blumenbach possesses a plaster cast. It is rendered doubly interesting, as it tends to confirm the testimony of the numerous travellers who have unanimously concurred in extolling the beauty of the inhabitants of Georgia and the adjoining country.

Plate CCXVIII. Fig. 3, 4, 5.

Fig. 5. represents the cranium of a Tungoose, from the north-east of Asia. The margin of the orbits and zygoma are elegantly contrasted in the Georgian; and the jaws are hidden by the beautiful expansion of the glabella. In the Negro, the maxillary bones, and indeed the whole face, are compressed laterally, and project in front. In the Tungoose, on the contrary, the ossa malæ, ossa nasi, and glabella, are situated on nearly the same horizontal level, and are enormously expanded on each side.

Craniometry, Cranioscopy.

Whilst we are on the subject of the *Norma verticalis*, it may be proper to mention an instrument invented by Dr Barclay, for measuring the various diameters of the cranium, Plate CCXVIII. Fig. 6. By a combination of all these characters, viz. *basi-facial angles, norma verticalis*, and the different *diameters*, we can, with unerring certainty, discover the nation to which the skull belongs.

For a description of the *occipital angle*, see the article Cranium.

Explanation of Plate CCXVIII.

Plate CCXVIII. Fig. 1—6.

Fig. 1, Exhibits the facial angle of Camper, or an outline of the cranium of a Negro, whose angle is 70°.

Fig. 2, Shows the inferior basi-facial line of Dr Barclay on the skull of the Babarossa *Vulgaris*, (Sus *Babarossa*, Lin.)

Figs. 3, 4, 5, are copied from the Decades of Blumenbach.

Fig. 3, Skull of a Negress from the coast of Guinea.

Fig. 4, Skull of a Georgian female.

Fig. 5, Skull of a Tungoose.

Fig. 6.

Fig. 6, represents the craniometer invented by Dr Barclay for measuring the diameter of the skull. The instrument consists of two thin slips of brass AA, separated from each other at their extremities by two little bits of brass or iron. Between these slips, so put together, is a groove through which other slips of brass BB and CC are passed; BB moving backwards and forwards like a shoemaker's instrument for measuring the foot, being kept steady by a spring D. It has likewise the power of being moved upwards and downwards, which latter is the only movement allowed to the slip CC, which is also steadied by a spring. These different slips are divided into any number of inches and tenths. The application needs no description, it being precisely that of a shoemaker's instrument.

Fig. 7.

Fig. 7, exhibits Dr Leach's craniometer for measuring the superior basi-facial angle of Dr Barclay. This angle is described above. AA represent two rods of brass, one turning on a pivot B. The skull is placed in the instrument, the teeth and alveolar processes being received into the notch F, by which contrivance an imaginary line is carried through the alveolar processes parallel with the palatine plate: (This notch may be closed by the slider E.) When the skull is in this situation, the rod AC is made to rest on the bones of the nose and forehead, (or on the junction of the nasal and superior maxillary bones); the end C showing the degrees of the angle on the semicircle D, without farther trouble. (W. E. L.)

CRANIOSCOPY, (from κρανίον *the skull*, and σκοπέω *to speculate*) is a science which teaches us to investigate the eminences produced in the cranium by the brain, and to discover, by such examinations, the particular part of the brain in which the individual organs, influencing our passions or economy, reside.

1. History of the Science.

This science is of very recent date, but as it is a subject which has excited a considerable interest, not in the public mind alone, but amongst the most eminent philosophers, we conceive it highly deserving a place in the present work. It was first proposed as a science by Dr Gall, a German physician of very considerable abilities, who, in the early part of his life, is said to have paid great attention to the study of natural history, employing his spare time in collecting animals and plants, and arranging them from their external characters, regardless of the systems of others, (of which he was probably ignorant). From these early habits of investigation, he very soon noticed a general form in the heads of such of his fellow-students as resembled each other in disposition and pursuits, which suggested the possibility of discovering the intellectual characters of individuals from an examination of the cranium. On minute investigation, however, he found the fallacy of his opinions, in consequence of which he retracted his general inferences, and directed his attention to the individual parts of the skull; at the same time calling in the aid of comparative anatomy; losing no opportunity of collecting skulls of every description, both of men and animals; and obtaining casts in Paris plaster of living characters of eminence. As his knowledge increased, he delivered lectures on the subject, until his fame reached the ears of the Austrian government, who, under the fatal administration of bigotted priests, thought proper to prohibit him from lecturing, because his doctrines were supposed to lead to materialism and atheism. He was, therefore, compelled to travel to the northern parts of Germany, and, in his route, he lectured at Dresden, Berlin, Halle, Jena, Gottengen, &c. and as his partizans were very numerous, and much in his interest, he was welcomed to the first tables, which enabled him not only to extend his observations, but to converse with learned men on the subject of his doctrines. He is now in Paris, where his abilities are duly appreciated, and he meets with the most liberal encouragement, not from scientific men alone, but from the French government; and, after a long series of years spent in laborious investigation, and in the collection of facts, he thinks himself justified in submitting the result to the public, which he is now doing in a most splendid work in the French language, entitled, *Anatomie et Physiologie du Système Nerveaux en général, et du cerveau en particulier; avec des Observations sur la possibilité de reconnoître plusieurs Dispositions Intellectuelles et Morales de l'Homme et des Animaux par la Configuration de leurs Têtes*, par F. J. Gall et G. Spurzheim. Vol. 1. *Anatomie et Physiologie du Système Nerveaux, en général, et du cerveau en particulier in quarto avec 17 planches in folio, et in duodecimo point planches.*

2. Gall's Opinions on the Anatomy of the Brain.

Before entering into a minute detail of particular organs, it may not be improper to give a slight sketch of the opinions entertained by Dr Gall, respecting the general anatomical structure of the brain. He is of opinion, that the encephalon, or brain, is not, as has generally been supposed by anatomists, a pulpy substance, but a membrane; and he infers this, from observing the unimpaired state of the intellectual faculties in the disease called *hydrocephalus internus*, where the brain is sometimes so much compressed, as to be scarcely a line in thickness. The spinal marrow too, which is generally said to be an elongation of the brain, he imagined must have an uninterrupted communication with it, from observing paralysis of the extremities from injuries of the hemispheres, and he was fortunate enough to verify this hypothesis, and to trace the connection. This is declared to be false by Professor Walter; but the writer of this article, in a recent brain, once saw this connection traced, and has no doubt that, under favourable circumstances, it may always be made out; but the brains we meet with in our dissecting rooms, are in too bad a state to admit of any accurate or useful investigation. The medulla spiralis is composed of nerves, and, like the brain, is divided into two equal halves, which again may be subdivided into fasciculi, separated from one another by a grey substance, which probably is appropriated to nourish and strengthen the nerves. This nervous stem grows stronger and larger as it proceeds upwards, until it terminates within the skull, and then the whole expands like the branches of a tree; thus, the nerves originate where anatomists have supposed them to terminate; the nerves being formed before the spinal marrow; the medulla spinalis before the brain; hence nerves are found where there is no spinal marrow, and in new born infants, the latter was observed to exist, by Gall, whilst there was no appearance of brain. Gall commenced his examination of the encephalon at the base, beginning with the cerebellum and spinal marrow, employing a blunt instrument, by this means unravelling the convolutions of which it is composed; and never using a knife or sharp instrument, which destroys its beautiful texture, and renders it one mass of confusion. The general results of his examinations tend to show, 1st, That the whole of the medullary substance of the brain and cerebellum consists of nervous fibres, which are nourished, intimately connected, and strengthened by the cortical substance, which is composed of ganglia. 2d, That the nerves, which constitute the essential part of the encephalon and spinal marrow, are of two kinds: 1. the excurrent; 2. the recurrent; all of which take their origin from the spinal marrow, and terminate in it; consequently, the medullary part of the encephalon is derived from the spinal marrow, and the cortical part is the superficial ganglion of the brain and cerebellum; and that all the excurrent nerves terminate in the outer surface of the cortical substance on which the tunica arachnoides rests, while all the recurrent take their rise at this place.

3. Physiology of the Brain.

The brain is universally allowed to be the organ of thinking, but thought is but a general term, including a vast number of intellectual phenomena, and the brain is a very complicated organ. Shall we then, says Gall, rest contented with the general assertion, that the brain is the organ of mind? He considers it as a congeries of distinct organs, the existence of which distinguish the different individuals hardly less from one another, than man is himself distinguished from other animals. Amongst various proofs of the real existence of separate organs in the brain, are the following: 1. The sense of fatigue, arising from the mind having been long employed in one subject of contemplation; and the relief and delight we experience in variety: this cannot have escaped the observation of the most cursory observer. 2. The degrees in which the different

Cranioscopy

faculties are possessed by the same individuals; and the evident superior strength of certain organs, which causes one man to be a poet, another a statesman, or a general, &c. 3. The loss of certain faculties and powers of mind, from wounds, diseases, &c. affecting certain parts of the brain. The functions of the brain are threefold; 1. organic life; 2. sensitive life; 3. intellectual life Gall to each of these assigns a particular organ: it is in consequence of the size of the hemispheres (the part appropriated to intellectual life) that man has the largest brain: and not because the size of the human brain is greater in proportion to the rest of his body, nor on account of the comparative thickness of the nerves, as Soemmering has observed. The hemispheres of the brain are developed, in different classes of animals, in proportion to their intellectual faculties, and they are more perfect in man than in any other animal hitherto discovered. This assertion, that man is endowed with the largest brain, ought not to be mistaken; for the elephant and several other animals, have a much greater brain than man; Gall only asserts, that the hemispheres in man are larger in proportion to his size; and that the nerves are always in proportion to the economy of the animal to which they belong; thus the optic nerve is much larger in graminivorous than in carnivorous animals, whereas the olfactory is much stronger in the latter; hence it appears, that animals are furnished with such organs as are necessary or best suited to their mode of life, and are consequently born with certain dispositions and inclinations, for the exertion of which they have received certain instruments, by means of which they hold an intercourse with the external world; these organs reside in the brain, the place of rendezvous of all the single organs; each innate disposition having an organ of its own, which is increased in proportion to the power residing in the disposition, and are expressed in the surface of the brain, and form certain protuberances in the exterior osseous cover of the cranium, by which the existence of these organs may be ascertained under certain restrictions; and from these observations the system of *cranioscopy* arises. These dispositions may, in some measure, be further developed by education and connection with the world, but can by no means be created by them; or certain organs which would be productive of evil to the individual possessing them, may in a great measure be repressed; for instance, if a young man has a melancholy turn of mind, full of nervous sensibility, conscious, and scrupulous, in whom also the organ of theosophy is found, Gall would recommend him not to follow the bent of his inclination, the profession of divinity, but to lead an active life, and to mix much with gay society; and this he asserts, would in a short time effect a change and permanent cure.

Organs peculiar to the human cranium.

The organs peculiar to the human cranium are, according to Gall, twenty-seven in number. These he divides into three classes.

I. Those by which man is enabled to enter into connection with the external world.

II. Those by which we are enabled to acquire a more intimate acquaintance with the world, or with certain objects which are made known to us by means of the external senses.

III. Those which constitute the peculiar prerogative of the human race, and which raise man more eminently above all other animals in the creation. All these lie on the vertex and glabellar portion at the os frontis, that feature considered by the poet as the glorious characteristic of humanity. The forehead rises in animals as they are advanced in the scale of intellect; but it is in some species of men alone that the glabella assumes that graceful swell, which Blumenbach observes *is no less beautiful to the eye of taste, than significant to the physiognomist.*

Particular Organs of the Brain.

Particular organs of the brain.

1. *The impulse to propagation, or organ of sensual love;* which is the most important, resides in the cerebellum, and comprises that part of the occipital bone, which lies below the linea semicircularis inferior, towards the great occipital hole: it is discoverable in living subjects by the thickness of the neck, and is always more prominent in the male than in the female. As the sensual passion arises, this part is developed; and when by castration the purposes of nature are defeated, this organ ceases to grow. In such as undergo the operation at an early age, the back of the head ceases to grow; the neck is narrow, and the voice looses its manly vigour. The thickness of the neck, in consequence of the large size of the cerebellum, is particularly observable in the bull and stallion. It is farther observed, that ossification increases as the brain diminishes; thus, if the horns of a stag be cut off in the rutting season, the animal loses its power of procreation, in the effort of nature to reproduce this substance; and it does not recover its generative power till the antlers are reproduced. Many phenomena, in cases of disease, tend to prove the existence of this organ: wounds of the back of the head will produce inflammation, and sometimes impotence; and in hydrops cerebri the power of generation remains undisturbed, whilst all the other functions of the brain are deranged; from a very natural cause, the cerebellum suffers least in this disease. Cretins, who are notorious for their lasciviousness, but scarcely possess the common intellectual powers, have their cerebellum remarkably large. The bust of Raphael, which was made from an impression in Paris plaster, has a very large protuberance behind, announcing that tendency of his constitution, to which he fell an early victim. Gall relates the case of an insane man who had a fixed idea that he had six wives, and his cerebellum was found remarkably distended at his death; and states, that on entering an hospital in which he had never been before, he heard a woman uttering the grossest obscenities: he desired his assistant, Dr Spurzheim, to examine her head, declaring that he would relinquish his doctrines, if her head was not found remarkably large behind, and he was not deceived.

2. *The organ of parental love and filial affection,* is placed at the upper part of the occiput, and is most intimately connected with the impulse to propagation, and hence the organ of parental love is situated immediately above it. It is found in all animals that are fond of their young, but is always more apparent in the female than the male. It is so evident in the human species, that the sex of a child at birth may be known by this single criterion. This organ is also expressive of filial love, and is in some measure developed in boys: it however dwindles away in time, in the same proportion as the affection of parents decreases for their children.

We now leave the inial part of the head, and proceed by the lower plane of the brain to that part of it which is situated in the glabella, where nature has placed those organs which the new-born animal needs, to get more immediately acquainted with exterior objects. These organs are placed near each other, and the inclinations combined with them, produce the possibility of first knowing things at large, then to compare them with one another, the relations of space, persons, colours, sounds, and numbers.

3. *The aptness to receive an education,* situated on the middle of the glabella, immediately above the nose. It exists in all animals that can be tamed.

4. *The organs of locality,* are situated on the superciliary ridge of the forehead, on each side of the organ of aptness to receive an education. It is observed in the heads of astronomers, in whom it is particularly conspicuous, and is generally attended with a prominent organ of numbers. It denotes an aptness of apprehending the proportion of space, and an inclination to all those arts and sciences, which chiefly depend on the perception, measurement, and proportion of space. Is often found in the heads of good landscape painters and surveyors of land; also in such as are said to possess an acute eye or good look, that is to say the skill to survey a bit of ground with quickness and precision. It further shews a disposition for wandering from one place to another, and is particularly prominent in the stork and other birds of passage. The capacity which animals have of following their masters, as well as of returning to their home, seems to depend on their influence, and not to scent alone, as many facts are known which do not admit of that explanation Gall relates an instance of a dog which was taken to England from Vienna, which soon escaped from its new owner, went alone to the port, contrived to get on board a vessel, accompanied a gentleman to Mentz, whom he there deserted, and took his course alone to Vienna. In men this organ operates variously; but in every instance is connected with a disposition to observe the relations of space. It generates a love for travelling; and all persons thus organised have a most surprising skill in finding their way in strange places. The portraits and busts of the most eminent travellers and navigators are marked by this organ.

5. *The recollection of persons.* This organ is placed within the cavity of the eye, and is much wrapped in obscurity. Gall observes that it is seldom very visible, because in the forehead are many more organs which counteract its effects.

6 *The disposition for colouring.* This organ forms a protuberance in the middle of the eye-brow, immediately by the side of the organ of locality. When much enlarged, it gives the eye-brow a peculiar arch. This is particularly evident in the skulls of eminent painters. The skill of colouring, says Gall, does not depend on the eye alone; for if that were the case, all such as have a good sight would be possessed of it.

7. *The organ of sounds,* appears above the exterior arch of the eye-brow, and sometimes extends backwards immediately over the organ of mechanical skill. It likewise includes a sense for time and rythmus.

8. *The organ of arithmetic,* is situated on the exterior angular process of the os frontis, immediately above the cavity of the eye; bounded on the inside by the organ of colours, and behind and above by the organ of sound. Whenever it is found in a high degree, there arises a swelling by the sides of the eyes towards the temples, giving a square form to the head. It is confined to man; hence the skulls of other animals are not so broad in front as those of man.

9. *The organ of words, or memory,* is situated on the upper and hinder part of the cavity of the eye, and proves its existence in the living subject, by forcing the eye downward and forward.

10. *The organ of languages,* or aptness to penetrate quickly into the genius of a language, or of stating our ideas in a clear and precise manner, is situated interiorly above the eyes, and shews itself by pressing the eye deep under the eye-brow downwards, and often occasions a swelling underneath the eye towards the nose. It exists in animals who have the power of making themselves understood to individuals of the same species by language.

11. *The organ of mechanical skill* occasions an arched elevation on the os frontis, below the place where the organs of thieving meet.

12. *The organ of friendly attachment* has its residence by the side of that of parental affection, and is expressed by two protuberances on both sides, towards the ear, where the parietal bones meet in the middle with the occiput, close by the sutura angularis.

13. *The organ of valour* is found in those most apt to fight and quarrel, forming an hemispherical protuberance on the lower and hindmost angle of the parietal bone, behind and above the ear.

14. *The organ of murdering* is situated about an inch behind, and a little above the zygomatic process of the temporal bone in man. It is found protuberant in all carnivorous animals, but is never visible in such as live on vegetables.

15. *The organ of cunning* is found on the lower angle of the parietal bone, about the breadth of three fingers above the meatus auditorius, and is confined anteriorly by the organ of larceny, and above by the organ of circumspection, behind and below by the organ of murder.

16. *The organ of larceny* is bounded on one side by the organ of sounds, below and before by the organ of mechanical skill, above by the organ of inference, behind by the organ of cunning. It denotes a propensity to utter cunning, and by means of it to deprive others of their property.

We are now come to those organs which are placed in the back of the skull.

17. *The organ of height* is situated between the inial and coronal aspects of the head, about the middle of the sutura sagittalis, behind and underneath the organs of perseverance, and between the organs of ambition: it is of an oblong shape, and was first observed by Dr Gall in a beggar, who lived upon begging, from a conviction that he was above receiving any instruction; he afterwards found it in children who mount chairs and tables, that they may appear as tall as others, also in such animals as live in cliffs and mountains; he called it the organ of height, to indicate at once all the inclinations dependant on it.

18. *The organ of ambition or vanity,* is situated by the side of the organ of height, in the inial angles of the parietal bones. It is more often distinctly expressed in women than in men, and is always found in the skulls of ambitious or vain persons.

19. *The organ of circumspection* is placed in the middle of the parietal bone, and imparts an aspect to the corono-inial part of the skull. These organs are found in all animals that act with particular caution. It is very evident in the deer, more so in the wild goat, and in rooks it is particularly prominent. In such men as are entirely destitute of this organ, that part of the skull where it resides is sloped back; it then indicates giddiness and thoughtlessness.

All the organs hitherto enumerated, are common to those animals known under the general title of quadrupeds. There are others, however, which are peculiar to man alone, which indicate more exalted faculties of mind, and distinguish him from all other animals; these organs must, therefore, reside in a part of the brain of which inferior animals are deprived; and it is that mass of brain which lies behind the upper front part of the forehead, which, as we have before observed, is peculiar to some species of man alone. This spot may be considered as the partition between man and all other creatures.

20. *Comparative perspicuity.* This organ is found in the middle of the glabella, immediately above the organ of memoria realis, or aptness to receive education; being bounded on each side by the organs of metaphysical perspicuity, and behind by the organ of good nature. It is found in the skulls of eminent lawyers, and in those men who have the skill of convincing people by similes. Gall observed it in several ecclesiastics that were known as popular preachers, who knew to persuade their audience by imagery, comparisons, and paraboles.

21. *The organ of metaphysical perspicuity,* was observed on the skulls of Socrates, Kant, Mendelsohn, Fichte, and many more deep thinkers, over the whole forehead, not quite on the top, being situated on each side of the organ of comparative perspicuity.

22. *Wit.* This organ is situated between the organs of metaphysical perspicuity, theosophy, of theft, and of sounds.

23. *Organ of inference* exists in such great men, as are enabled to arrange their ideas with precision and ease. It arises from the confluence of the organs of perspicuity, deep thinking, and wit. It causes the whole upper part of the forehead to bulge forward. It has been observed by Dr Gall in the heads of Boerhaave, Haller, &c. and by the writer of this article in the skulls of Hunter, Burke, Fox, Stewart, and other great men possessing capacious and comprehensive minds.

24. *Good nature* is placed on the corono-glabella portion of the middle of the os frontis. It is very conspicuous in the heads of good-natured persons and domestic animals, as the greyhound, &c.

25. *Theosophy,* or *godliness,* is placed on each side of the organ of good nature. It is of rare occurrence. When found, it causes a swelling in that part of the cranium, often combining with the organ of good nature, causing the hair to divide, and fall down on each side of the head. Gall observed a tendency to baldness in such as possessed this organ, of the existence of which he has no doubt.

26. *Perseverance,* resides on the coronal, on the angles formed by the junction of the coronal and sagittal sutures.

27. *Mimicry,* is placed on the coronal aspect, on the inial portion of the os frontis iniad of the organ of perseverance. It is always found in the skulls of mimics and eminent comedians. It is very conspicuous in the busts of Garrick and others.

We have now enumerated the organs supposed by Dr Gall (at the time he lectured at Dresden) to belong to the human cranium; on the truth of which we shall not hazard an opinion, but refer such of our readers, as wish a more minute account, to the following works: *Anatomie et Physiologie du Systême Nerveaux en general, &c.* par F. J. Gall et G. Spurzheim. *Lettre de C. Villers a G. Cuvier, sur une Nouvelle Theorie du Cerveau,* Mentz 1802. *Edinburgh Review,* No. iii. Art. 15. *Representation of Gall's Theory of the Brain and Cranium,* by C. H. Biscroff, professor of anatomy at Berlin, with remarks by Dr C. W. Hufeland, director of the Medico-chirurgical College, Berlin, octavo, in German. *Some Accounts of Dr Gall's new Theory of Physiognomy, founded on the Anatomy and Physiology of the Brain and form of the Skull,* London, 8vo. 1807. An analysis of this pamphlet may be seen in the *Edinburgh Medical and Chirurgical Journal* for July 1806. An anonymous work entitled, *Dr F. J. Gall's System of the Functions of the Brain, extracted from Charles Augustus Blode's Account of Dr Gall's Lectures held at Dresden, translated from the German, to serve as an explanatory attendant to Dr Gall's figured Plaster Skulls.*

We cannot conclude, without noticing some of the objections urged against this hypothesis of Gall. He has been accused of describing prominences on those parts under which there is no brain. Thus the root of the nose and eye-brows assume a shape of greater or less prominence, according to the size of the frontal sinuses, which vary greatly in different individuals; yet over these cavities he places the organs of memory and colours; and over the spine of the frons, the organ of aptness to receive an education; and his organ of music, on the external angular process of the same bone. It is farther asserted, that, on contemplating the surface of the hemispheres in the situation pointed out by Gall, we meet with no prominences where he describes these organs to exist, but find the brain to present an uniform and general convexity. We have now given the opinions of Dr Gall, and the principal objections brought against them by his opponents. Our limits, however, will not allow us to discuss the point, as we could wish. Indeed we are very unwilling to say more on the subject, until we have perused his last work, and heard his last opinions, which would have considerable weight in terminating the dispute. (W. E. L.)

CRANIUM, from κρανιον, *the skull,* is that division of the head which contains the brain. Some derive the name from κρανος, a helmet, because it protects the brain as a helmet does the head. In different authors the following synonymes occur, *Calvaria, Cerebri galea, Testa,* or *Scutella capitis;* κογχος, κυτος, and σκαφιον.

For an anatomical account of the cranium, see ANATOMY; and for an account of the national varieties, see MAMMALIA. We shall now make some general remarks on the skulls of animals in general. An obvious and very striking difference exists between the heads of man and all other animals, consisting principally in the relative proportions of the face and cranium, which are made obvious by the facial, and basi-facial angles. The facial angle (as we have before observed in the article CRANIOMETRY) is greatest in man. The face of animals is situated more antiniad than in man; and the cavity of the skull is so diminished in size, that its anterior or glabellar portion is soon lost as we recede from man. Hence the facial line is oblique, aud the facial angle is acute, and it becomes more so as we descend in the scale from man; and in some birds, and most reptiles and fishes, is lost altogether, as the cranium and face are completely on a level, and form parts of one horizontal line. The idea of stupidity is always associated with an elongation of the face, which lowers the facial line; hence the snipe and crane have become proverbial. When, on the contrary, the facial line is increased, with no expansion of the cranium, as in the elephant and owl, by the cells which separate the two tables, the animal acquires a particular air of intelligence, and gains the credit of qualities which he does not possess. Hence the latter animal is selected as the emblem of Minerva, and the former is distinguished (as we are told) in the Indian language, by a name which indicates an opinion that be participates with man in his most distinguishing characteristic, the possession of reason. The ancients (as we have already mentioned under CRANIOMETRY) were well acquainted with these circumstances, and have extended the facial angle of their heroes and philosophers to 90°, and that of their gods to 100°.

The foramen magnum occipitale in man, is placed in the basilar aspect of the head, near the middle, being but little iniad of the middle part of the base, and its direction is nearly horizontal. As we descend in the scale of beings it recedes iniad, and in the lower animals we find it situated in the inial aspect. This was first noticed by Soemmering. The situation of this foramen is admirably adapted to the economy of the animals, and the positions they assume in walking. In proportion as the volume of the brain increases in comparison to the whole body, so does the occiput become more convex and prominent; and the foramen magnum is removed farther from the inial aspect, and the level of this opening approaches the horizontal direction. This position of the opening, which places the head in a state of equilibrium upon the neck, and brings the face forwards in the natural erect position, would, if man went on all fours, prevent him from elevating the head sufficiently to see before him, because the motion of the head would be stopped by the projection of the occiput meeting the cervical vertebræ.

As the situation of the occipital hole differs very considerably in various animals, it has become a matter of importance to distinguish by some determinate rule its variation; for this purpose let a line be drawn along the level of this opening; it will pass from the inial edge of the foramen, along the surface of the condyles, and if continued anteriorly, will terminate just under the orbits. It forms a short and almost horizontal line, which intersects, nearly at right angles, the vertical line of the body and neck, when the head is held straight, being neither inclined backwards or forwards.

The difference in the direction of the foramen may be estimated by noting the angle formed by the union of a line drawn in the manner above-mentioned, according to the direction of the opening, with another line passing from the posterior edge of the foramen to the inferior margin of the orbit. Their angles is of 30° in man, and of 37° in the orang-outang. The same angle which is termed the *occipital angle*, is 47° in the lemur, and 90° in the horse.

Other differences, existing in the teeth, upper jaws, &c. are noticed as characters by which man is distinguished from other animals. For a more particular account of these distinctions, see ANATOMY, MAMMALIA, and TEETH. (W. E. L.)

CRANMER, THOMAS, archbishop of Canterbury, was born at Aslacton, in Nottinghamshire, July 2, 1489. His father, who bore the same name, was a gentleman of a family which for many ages possessed Cranmer Hall in Lincolnshire, and is said to have been able to trace his pedigree to the time of the conquest. The advantages of a well-directed education, which young Cranmer improved, formed at a very early period his manly character, and laid the foundations of his future fame. His admittance into Jesus College, Cambridge, when only 14 years of age, opened up a wide field for the exertion of his keen and piercing intellect; but though the range of his understanding was only bounded by the whole circle of science, yet religious, and, in particular, biblical knowledge, was his favourite pursuit. A fellowship, and a degree of master of arts, were the honourable rewards of his abilities and industry; but the former he forfeited by marrying a lady to whom he was tenderly attached; and he immediately after became reader in Buckingham College. The happiness which he enjoyed in the fond affection of a kindred spirit, was cruelly terminated by the death of his wife, which took place a short time after his marriage; but if his affliction could have been soothed by the love and esteem of the good, he must have found some consolation in the admiration of his friends, who again dignified him with his fellowship in the university, an honour almost unprecedented. Refusing a fellowship at Oxford, which Cardinal Wolsey offered him, he took the degree of doctor in divinity, 1523, and, in consequence of his integrity and learning, was appointed to give lectures on theology, and to examine the candidates for academical honours. Even in that age of comparative darkness, the penetrating mind of Cranmer, though still entangled with the bewildering dogmata of papal superstition, had learned, from an intimate acquaintance with the scriptures in their original language, not merely to despise as useless, but to detest as destructive of the beauty and the power of religion, all those distinctions without difference, all those technical phrases without meaning, and all those definitions of things undefinable, which composed the lifeless body of school divinity, and which, in some degree, are blended with the systematic religion of the present day. Hence, as he refused degrees in divinity to every person who was ignorant of the language and doctrines of scripture, he became, at first, obnoxious to the ignorant and the ambitious; but, in a short time, many of those who most bitterly reproached him, were filled not only with admiration of his virtues, but with gratitude for the happiness which he had conferred upon them.

To fulfil Cranmer's future destiny, he was forced by the plague, which broke out at Cambridge, to visit a Mr Cressy, an intimate friend of his, who resided at Waltham Abbey. Whilst he enjoyed there the pleasures of literary friendship, Henry VIII. who, in 1529, sought to divest his mind from the disappointment which he experienced in his divorce from Catharine of Arragon, took a tour through part of his kingdom, and happened on his return to stop at the house of Mr Cressy. Here Dr Fox, the king's almoner, and Dr Gardiner, then secretary, afterwards bishop of Winchester, met with Cranmer at supper, and as the king's divorce became the subject of conversation, Cranmer, from that acute discernment which he naturally possessed, observed, that whilst they paid such unlimited regard to the ecclesiastical law, the business would never be terminated: the question was simply, "whether a man may marry his brother's wife?" This could be decided by scripture only; and if the universities of Europe were consulted respecting the doctrine of scripture on this point, the affair would soon be over; for if the scriptures permitted it, the conscience of the king would be at rest; and if they did not permit it, the authority of scripture, supported by the suffrages of all the learned bodies in Christendom, would compel the pope to pronounce a definitive sentence agreeable to scripture. Fox and Gardiner, struck with the force of the observation, resolved to communicate the information to the king; and justice requires that we should state, that whilst the latter invidiously proposed to conceal the author, and take the merit of the discovery to themselves, the former generously rejected the unmanly proposal, and fairly revealed the scheme and its author to Henry.

From this moment, Cranmer's history becomes, in a great measure, identified with the history of England. As the narration of public events belongs much more properly to the annals of the kingdom, than to the biography of the man, we shall touch but slightly upon those circumstances which must compose a prominent part of the history of that important period, and confine ourselves chiefly to the private events of the individual.

Cranmer had left Waltham, before Henry was informed of his advice; but the king was so enraptured with the design, that he sent an express for him to Nottinghamshire. He, with that modesty which was natural to him, reluctantly obeyed; and soliciting in vain to be excused from appearing before the king, had an interview with his majesty. Pleased with his candour and discernment, the king made him one of his chaplains, requested him to write upon the divorce, and desired the father of Anne Boleyn, now Earl of Wiltshire, to allow him, at Durham Place, to pursue his design. From every source of legitimate reasoning, Cranmer established the important truth, that the pope possessed no power to dispense with the word of God, and not only by the unanswerable work which he published, but by public disputations, he gained almost every person of discernment to his opinion.

When the English universities had declared the marriage unlawful, an embassy, composed of the most learned men of the nation, among whom was Cranmer, was sent to Rome, to obtain, if possible, the pope's consent. This proved unsuccessful, from the political views of his Holiness, who, however, to conciliate all parties, as far as his double policy could go, bestowed upon Cranmer the office of penitentiary. From Rome, Cranmer went through Italy, France, and Germany, where, according to the custom of the age, he maintained the cause of his master in many public disputations. At Nuremberg, he married a second wife, the sister of the famous Osiander. On his return, March 13, 1533, the king conferred upon him the archbishoprick of Canterbury, and procured from the pope the bulls necessary for his consecration; but as he now began to embrace the opinions of the reformers, he refused to take the customary oath of obedience to his Holiness. He was at last, by the importunity of the king, prevailed upon to comply, by adopting an expedient which had been proposed to him, doubtful, at least, in principle, and dangerous in practice, but an expedient to which his mind perhaps was the more easily reconciled by the sentiments of the age, as well as by the common practice of that church which he wished to abandon. This was nothing else, than to enter a solemn protest, before he took the oath, that he did not intend by it, to restrain himself from any thing that he was bound to, by his duty to his God, his king, or his country. On the 23d May of the same year, he pronounced the sentence of divorce between the king and queen. The pope, upon this, threatened him with excommunication. He, in return, promoted the reformation to the utmost of his power; and was the principal mean of abolishing the pope's supremacy, by act of parliament—of procuring a new and more correct translation of the scriptures—and of suppressing the monasteries. In 1536, he, in compliance with the will of the king, dissolved the marriage of Henry and Anne Boleyn; but though at her death the hopes of the Catholics revived, yet the means which they employed to counteract the reformation, and to withdraw from Cranmer the affection and confidence of the king, had a contrary effect. Hence the *constitutions*, which were enacted this year by the convocation, corrected many errors respecting purgatory and images; but they determined a point of still greater importance, when they declared the scriptures to be the standard of faith. But the triumph of truth was soon blasted, by an act of parliament in 1539, for abolishing diversity of opinion in religion—an act which, by its being sanctioned by the gibbet and the flames, was emphatically called the *bloody statute*. This, though approved by the king, was framed by the artful and insidious suggestion of Gardiner, bishop of Winchester, whose spirit it breathes; and which, by denouncing all who denied transubstantiation, the celibacy of the clergy, &c. must have fallen chiefly upon the reformers. With a modest, but manly fortitude, which must exalt the dignity of Cranmer's character in the eyes of all capable of appreciating truth and freedom, he opposed the enactment of this statute with all his eloquence and authority. Even when required by the king to leave the House, he refused, by declaring, that he was bound in conscience to vote against it,—a declaration which his enemies fondly hoped would for ever ruin him with the king; but which, in reality, gave the king such a high idea of his integrity, that he respected and trusted him the more. But though he opposed the law in the House, yet he complied with it so far, when passed, as to send his wife to her friends in Germany, till better days should arise. In 1540, he received the royal commission to provide for the advancement of religion, by explaining its principal doctrines, which he performed by the publication of a work entitled, "A necessary Erudition of any Christian Man;" a work which the votaries of Rome endeavoured in vain to answer.

We cannot refrain from bringing forward here an event, which will shew the malevolence of the primate's enemies, and the affection of the king. It is well known, that Henry persecuted, with the same severity, the opinions of reformers and Catholics, when they differed from his own; and that every person who would not subscribe his creed was a heretic. The natural consequence of free inquiry, was a variety of opinions; and Gardiner and his adherents, taking advantage of this, endeavoured constantly to impress the king with the belief, that Cranmer was the sole cause of the growing mischief. To repress at once their insinuations, which continually teazed him, he appeared to enter into their views, and permitted them to summon the archbishop to appear before them next day. At midnight, however, he sent Sir Anthony Denny to request Cranmer's immediate attendance in the gallery, and in all the confidence of friendship informed him of their machinations, and advised him not to commit himself to their mercy by any unguarded concession; "for he would not have any better luck with the false knaves than his master, Christ, had." At parting, he gave him a ring from his finger, as a pledge of his protection; and Cranmer retired, so deeply affected with the king's goodness, that he scarcely refrained from tears. When summoned next morning to attend, he obeyed, and his enemies were so confident of success, and so insolent in their malice, that they refused him admittance to the council-chamber, till Dr Buts, the king's physician, informed his majesty that the primate of England was thus degraded like a foot-boy. When admitted, he was charged with heresy, and with protecting heretics; and was ordered to be committed to the Tower. The production of the ring was a stroke of thunder to his enemies. Equally abject in adversity, as proud in prosperity, they first broke out in reproaches against each other, and then in apologizing to the king; who told them, that he thought his council had been composed of wiser and better men, than to persecute the only person of integrity among them. After the death of Cromwell, Earl of Essex, whose execution the generous friendship of Cranmer laboured in vain to prevent, he retired to the duties of his clerical office; and left the court to those who, by their ambitious and crooked policy, were better calculated for rooting in that polluted soil. The king, however, not forgetful of his integrity and moderation, appointed him one of his executors; and in his last illness sent for him from Croydon to assist him in his preparation for eternity. Before he arrived the king was speechless; but as a proof that he knew him, he pressed his hand and expired.

Though Cranmer placed the crown upon the head of Edward VI. and was nominated one of the regents, yet he interfered in civil affairs only when they were connected with religion. But as the mind of the prince had fully imbibed the principles of the reformed, the designs of the Archbishop were no longer impeded by the caprice of royal authority; yet, as he had many and powerful enemies, he proceeded in the work of reformation with a firm and steady pace, but at the same time, with a prudence which the more ardent of his party blamed. It is with real pity, and even indignation, that we see a mind, naturally mild, generous, and intelligent, still so embittered with the unrelenting spirit of bigotry, as to wield the sword of persecution, and to imprison Gardiner, Bonner, and some others, for their attachment to Popery. But what must be our feelings, when we contemplate him directing the secular power against Joan Bocher, commonly called the Maid of Kent, who denied the divinity of Christ. Her moral conduct was irreproachable, and with a constancy and courage which ought to have commanded the admiration of her persecutors, she refused to purchase life, by abjuring what she believed to be the voice of revelation, but what her enemies denominated a damnable heresy. She was sentenced to the flames; but to the eternal honour of Edward, his mind revolted against signing the warrant for her execution, declaring, that to burn any for conscience sake was a piece of cruelty too like that which the reformers condemned in Papists; and when Cranmer urged him to comply, "What, my lord!" was his animated and emphatic question, "Will you have me send her quick to the Devil in her error?" By the persuasion of the primate, in an hour fatal to his fame, the generous feelings of the prince were overcome, and he signed the warrant with tears, protesting, that if he did wrong, his advisers must answer for it to God.

In 1551, Cranmer followed the example of other reformed churches, and under his direction, if not with his assistance, a Confession of Faith was prepared, the new liturgy was corrected, and the articles of the Church of England, forty-two in number at that time, were established by law. But the hopes of the reformers were soon disappointed by the premature death of Edward, in 1553, who, however, in his last illness, in order to secure the ascendancy of the reformers, was prevailed upon to devolve the crown upon Lady Jean Gray. Cranmer refused to sign this settlement as a counsellor, but did it as a witness; a distinction of doubtful interpretation, though it is probable that he acted in this manner, not so much from an aversion to the deed itself, as from the fear of its consequences, as he afterwards composed one of her council. The accession of Mary, and the change of religion which immediately followed, banished, with respect to the reformers, mercy and even justice from the throne. Cranmer had now nothing to expect but the most unrelenting persecution; and, with a fortitude and a dignity, which, though seldom found with such moderation and prudence, he knew upon great occasions to display, refused, at the earnest solicitation of his friends, to seek his safety in a foreign country. The honour of his own character, the interests of truth, he said, imperiously commanded him to remain firm at his post; and to vindicate the changes which he had adopted in religion, he determined to wait the consequence. To deprive him not merely of life, but even of reputation, was resolved upon by his enemies. For this purpose, Bonner, bishop of London, degrading himself more than the victim of his resentment, burst out every where in spiteful railleries against Mr Canterbury, as he was pleased to call him, and published a report that the archbishop, in complaisance to the queen, had promised solemnly to abjure his errors. Into a snare thus cunningly prepared, and dexterously concealed, the wounded indignation of Cranmer betrayed him; and the refutation of this calumny which he published, and in which he called upon the queen to attest his innocence, sealed his doom. He was cited before the star-chamber; he owned the publication, and, contrary to the expectations of all, was pardoned by the queen. This lenity strikingly discovers the casuistry of Mary. Cranmer had generously interposed with her father, when he had resolved to put her to death for her adherence to her mother, and as she owed her life to him, she thus discharged her debt of gratitude, with the fixed resolution of afterwards demanding from him her full debt of vengeance, which she well knew she could enforce. Three days after his liberation, he was committed to the Tower, where he remained till 1554, when, with his fellow-prisoners, Ridley and Latimer, he was conducted to Oxford, to dispute publicly with the leaders of the Catholics, at whose head was Weston, prolocutor of the convocation. The court party, by this exhibition, designed to expose and degrade the three venerable reformers; and this they accomplished by shutting their ears to truth, and silencing their opponents by insult and tumult; and they terminated this solemn mockery of truth and justice, by pronouncing them heretics, commanding them to abjure their heresy, and excommunicating them upon their refusal. But, as the power of this court extended no further, in September 1555, Cranmer was brought to a second trial at Oxford, before Dr Brooks, bishop of Gloucester, and sub-delegate to the Pope, Dr Martin, proxy to the king, (Philip of Spain,) and Dr Story, proxy to the queen. That he had been twice married; that he had published heretical books; that he had forsaken the church of Rome; and that he denied transubstantiation, were the horrid crimes which were laid to his charge, which he confessed; and to answer for which he was cited within eighty days to appear before the Pope. When we say, that he was immediately remanded back to prison, it will not be necessary to add, that he did not obey the citation; but without recollecting the spirit of his persecutors, posterity will scarcely believe, that on the 14th February, Bonner and Thirleby were sent to degrade him for non-obedience. Though he defended himself with great eloquence and spirit, and protested against the injustice of a sentence condemning him for not appearing at Rome, whilst they detained him in prison, Bonner proceeded to the work of degradation with unrelenting cruelty. To expose him to ridicule, the archbishop of Canterbury was arrayed in pontifical robes made of coarse black canvass; these were taken off him piece by piece, according to the ceremonies appointed in such cases by the church of Rome; and a sentence adjudging him to the flames was pronounced. The patience and fortitude which he displayed, contrasted with the insolence and cruelty of Bonner, not only melted Thirleby into tears, but will transmit to posterity the name of the former with deserved infamy!

His immediate execution would have prevented Cranmer from clouding the evening of his days by an unavailing dereliction of principle. Unfortunately for his fame, he was remanded to prison: there he was assailed by the treacherous promises of his enemies, who assured him of pardon upon his gratifying the wishes of the queen; and by the no less urgent solicitations of his friends, who conjured him to relax his unbending spirit, and to yield to the storm, with which it was in vain to contend. In the gloom of confinement and of solitude, the dread of perishing amid the flames shook his virtuous resolution; the love of life, and the hope of being useful to his country, awakened in his bosom; and in an evil hour he signed that recantation of his religious principles which has to the present moment inspired men with grief or with exultation, according as they have been the friends or the foes of the reformation. The victory which the treachery of his enemies had gained, their malice knew how to improve. His recantation was printed and circulated with the utmost assiduity; the queen, that he might not have time to return to a better mind, resolved upon his immediate execution; and a warrant, to that purpose, was signed on the 24th February. This his enemies designed to conceal from him, but he suspected their design, and prepared for the consequences. On the 21st March, he was conducted in solemn procession to St Mary's church, Oxford; he was placed upon a platform raised opposite to a pulpit, where Dr Cole, provost of Eton, was appointed to preach before him a sermon suited to the occasion; and whilst the preacher deferred his appearance, that the fallen victim of superstition might be fully exhibited to the mockery of his enemies, he turned his venerable face to a pillar that was behind him, in all the wretchedness of degraded dignity. The mean and the tattered garments which covered him; the agony of his soul, which appeared in every feature of his countenance; the silent prayer which, in the bitterness of his spirit, he poured out to the Friend of the afflicted; and the awful circumstances in which he was placed, exhibiting an affecting instance of the instability of human greatness, might have softened the heart even of his persecutors. Dr Cole, however, at last ascended the pulpit, and after expatiating, with insulting malignity, on the errors and the punishment of the enemies of religion, he turned to the wretched victim of his cruelty, and thanking God for his return to popery, which he attributed to the agency of the divine Spirit, he assured him that his death should not be comfortless, as the priests there present would pray for his departing soul; but as a proof of his sincerity in returning to the bosom of the church, he commanded him to read aloud the abjuration of his errors. The aged primate, who stood an image of sorrow and contrition during this scene of insult and cruelty, with a firm and manly voice, professed his belief in all that the scriptures reveal to man; but, added he, "that which I wish chiefly to mention, that which wounds my conscience more than all the sins of my life, is, that, contrary to truth, and the dictates of conscience, I abjured the religion which I had embraced from the deepest conviction; and to repair, as much as is in my power, the majesty of truth which I have shamefully violated, I now renounce all the errors, which, in opposition to my better judgment, my hand has subscribed; and, as a mark of my detestation of my crime, the hand which committed the deed shall be first consumed in the flames which you prepare for me!" The spectators, who imagined that the sorrow which he displayed had arisen for the crime of apostatizing from popery, no sooner heard this declaration, than they loaded him with the most barbarous execrations. Dr Cole, with the wildest fury, cried out to stop his mouth! to pull him down! to drag him to the flames! His commands were obeyed with the most savage inhumanity. When he was chained to the stake, he bade the multitude, who reproached him, farewell; and perceiving one Ely, formerly an intimate friend, and a fellow of the same university, standing near, he offered him his hand, but he refused to touch so vile a heretic. He then stretched his right hand amid the flames that now rose around him, exclaiming, This is the hand that did it! Once only he removed it, and drew it across his forehead; and returning it again, he held it firm till it dropped from his shoulder. Unmoved like a statue, he stood with unshaken fortitude, and when the fire seized upon his vitals, he raised his eyes to heaven, and uttering the words of Stephen, "Lord Jesus, receive my spirit!" sealed his testimony by his death.

Such was the fate of Thomas Cranmer, Archbishop of Canterbury, in the 67th year of his age. Had he fallen in better days, his life would have exhibited every virtue which can adorn the man, or dignify the Christian; and he would have descended to the grave without those shades, which circumstances of peculiar difficulty threw upon the fulness of his fame. The praise and love of his friends are not a more decisive proof of his distinguished learning and abilities, than the reproach and hatred of his enemies; and the arts and labours which the votaries of Rome have employed to blacken his character, evince how skilfully he wielded the powers of a superior mind against the foundations of their church. Mild, modest, temperate; he conciliated the affection, without rousing the envy of those whom he surpassed in the race of civil or ecclesiastical preferment; and the noble stand which he made in defence of the Duke of Norfolk, his constant and determined enemy, when attainted by Henry contrary to justice, raised a column to his integrity and generosity which will never be shaken. With a mind patient in the investigation, piercing in the discovery, and ardent in the love of knowledge, he was admirably qualified to detect error, and to appreciate truth; and the intimate friendship which he cultivated with men of learning, as well as the patronage and protection which he extended to every branch of science, proved, that he beheld in others with pleasure those qualities upon which depended his own fame. But, whilst we love and admire the mild and splendid virtues which he possessed in an eminent degree, we are not blind to the failings and weaknesses which attended them. That he uniformly employed his influence to moderate the passions and soften the asperities of Henry's temper, will not, at all times, justify his complaisance to the wishes of that monarch. That he was open and sincere in his attachment to truth, will hardly excuse the manner in which he took the oath of allegiance to the pope, and signed the will of Edward; though it must be confessed, that had he made no scruples upon these occasions, we perhaps would never have blamed him, though his candour and integrity would have been less. The prudence, moderation, and generosity, which never failed to shed a dignity over his political conduct, will not atone for the imprisonment of the Catholics, far less for the death of Joan of Kent. His acts of persecution, however, must, in some measure, be imputed to the age in which he lived, and the church in which he was educated; and we cannot suppress a remark, which forcibly struck us when recording his interview with Edward, when he signed the warrant for Bocher's execution, that the youthful mind of that prince, who had imbibed without mixture the pure doctrines of scripture, felt the generous and liberal spirit of Christianity more than the learned and venerable Archbishop, whose mind still retained the traces and the temper of opinions, which had been deeply impressed upon it in a darker age. We can enter too into all his feelings, and sympathize with the weakness of human constancy, yet when we consider the distinguished eminence on which he stood in society, we are astonished that he could stoop to purchase the very dregs of life by an abjuration of principle; and we turn with a melancholy triumph to the noble and undaunted fortitude, which his closing scene presented to obliterate the remembrance of his fall. CREDITON, commonly called *Kirton*, is a market town of England, in Devonshire, situated on the river Crede or Creedy, in a rich soil between two hills, the southernmost of which overlooks the tops of the houses. The town is about a mile long, and is divided into the east and west parts, the latter of which was nearly destroyed by fire in 1743, and also in 1769, when several new buildings, and the market house and shambles, were consumed. The church, which was once a cathedral, is a fine and spacious Gothic building, about 150 feet long and 44 broad. It has the form of a cross, with a tower 100 feet high, rising from the intersection of the nave and transept, and standing upon a semicircular arch, supported by four enormous pillars. The tower contains eight bells, and a clock with chimes. The east and west windows are very large, and ornamented with tracery, and the interior of the church is neatly finished. The altar piece, which is esteemed an exquisite piece of painting, represents Moses and Aaron sustaining the decalogue, and extends through the whole height and breadth of the chancel. Over the south porch there is a small library, and there is a Sunday school connected with the chancel.

There is a good free school at Crediton, founded by Queen Elizabeth, and also a charity school for 40 poor boys and girls. The principal manufacture is that of serges, which are sent to Exeter to be finished and exported. Great quantities of wool and yarn are sold at the weekly market, which is held on Saturday.

The population of the burgh, in 1811, was,

Inhabited houses	425
Number of families	464
Ditto employed in agriculture	44
Ditto in trade and manufactures	369

CREED. See CONFESSION.

CREEKS. See GEORGIA.

CREMATION, is a term generally applied to the ancient custom of burning the dead. In our article BURNING, where we have given a full account of this custom, we have referred to the present article for an account of the ceremonies which accompany the burning of the living; but this subject will be more properly treated in our article INDIA, where we shall have occasion to treat at considerable length of the manners and customs of the Hindoos.

CREMONA, a town in the kingdom of Italy, and principal place in the department of the Po, is situated in a beautiful plain watered by the Oglio, and about a quarter of a mile from the north bank of the Po. The city is large and well built, and occupies a space about five miles in circumference. The principal streets are straight and spacious, and the town is adorned with some small squares, and several palaces.

The principal public buildings are the cathedral, St Peter's church, the Dominican church, the Augustines church, the town hall, or the public palace, and the university. The cathedral, which is of Gothic, or rather mixed architecture, was begun in 1107, but was not wholly completed till the 14th century. The front is lined with red and white marble, and is highly and fancifully ornamented. The chapel appropriated for the relics of the primitive martyrs, is a small though perfect edifice. It is simply and chastely decorated, and contains the urns and sarcophagi in niches regularly arranged on each side of the chapel, like the ancient Roman sepulchres. The cathedral contains several fine paintings and altars, and a handsome monument erected to the memory of Cardinal Francesco Sfondrato, decorated with fine bas reliefs. Before the entrance of the cathedral are two lions, each supporting a pillar. The baptistery, which is separate from the cathedral, is a large and lofty octangular edifice with two galleries round the upper part of it. It contains, in the centre, a curiously wrought font cut out of an immense block of party-coloured marble. The tower, which is very high, of a singular style of architecture, is ascended by 498 steps, and commands a fine view of the town, the various roads that cross the country, the Po intersecting the extensive plains of the Milanese, the Alps to the north, and the Appennines to the south west, covered with snow. Among the paintings in the cathedral, the crucifixion, by Pordemoni, is particularly admired. The principal paintings, however, were carried off to Paris when the town was taken by the French.

St Peter's church, which belongs to the canons regular, is a handsome edifice, adorned with many elegant paintings. The Dominican church contains a superb altar made of *lapis lazuli*, agate, and beautiful marble; and in the area before the church is a statue of St Dominic holding a cross in his right hand, and in his left a dog with a lighted torch in his mouth. This church contains likewise some fine paintings. The convent of the Augustines has a good library, and their church possesses some valuable paintings. The university of Cremona was long ago in a declining state.

A canal, which passes through the town, forms a communication between the Oglio and the Po, over the latter of which rivers is a bridge of boats, defended by a fort. The fortifications of this town consist chiefly of a wall with some bastions, and surrounded with a ditch, which is filled with water from the canal.

Cremona was once celebrated for its knives; and its violins and other musical instruments, which are held in high estimation, form a considerable article of commerce. Its principal exports are silk, corn, flax, oil, honey, wax, brandy, and Parmesan cheese, and its imports are linen cloth, silks, sugar, coffee, &c. Population 21,000. East Long. 10° 2′ 12″, North Lat. 45° 7′ 43″. See Keysler's *Travels through Germany*, &c. vol. iii. p. 337. Denina's *Tableau de la Haute Italie*, p. 249; and Eustace's *Classical Tour through Italy*, vol. i. p. 115, 118. (π)

CREMONA STOP, in music, is a simple reed stop, or consisting of only one range of pipes, that are tuned to their own or to the diapason pitch, the same as the finger-keys indicate, which is not the case with several even of the simple stops on the organ: its name is supposed to be a corruption of the ancient instrument krum-horn, which this stop, when first introduced, was said to imitate. CRETE, one of the islands in the Grecian archipelago, and renowned in ancient times for the fertility of its soil, the number of its inhabitants, and the wisdom of its laws. Under CANDIA, its modern appellation, we have given an account of its geography and present state; and in this article, we propose to confine ourselves entirely to a view of its ancient inhabitants and history. In entering upon this subject, however, we do not pretend either to reconcile the discordant accounts of ancient authors, or to unravel the mythological fables by which the early history of this island is so completely obscured. This would be a task more arduous even than to trace the windings of its famed labyrinth without the clue of Ariadne; and would lead us into disquisitions neither very interesting nor instructive.

At an early period of the world, Crete had made great advancement in civilization, while the other states of Greece were immersed in ignorance and barbarism. It possessed a free and regular government; and a system of laws which has been the admiration of succeeding ages. But what were the steps by which this island had arrived at such an extraordinary superiority over the surrounding nations, it would be in vain to enquire. Every account that has been received from the ancients, is completely involved in allegory and fable. Written records at that early period were unknown, and consequently all our information respecting it rests entirely upon vague and uncertain tradition. Most of the absurdities that have been embodied into the Heathen mythology had their origin here; and Crete may be justly said to have been the cradle of the gods. Such of their princes, as were distinguished for their wisdom, their valour, or their beneficence, were after their death raised to the rank of deities; and the high esteem in which the Cretans were held among the other inhabitants of Greece soon gained them admission into the worship of their more barbarous neighbours. Indeed it may be safely affirmed, that there is scarcely a divinity in the whole system of Grecian theology that did not receive his title and his honours in the island of Crete. It is to be regretted, however, that so little is known with certainty concerning this civilized people. Before the Trojan war, when they were in the height of their glory, their history is dark, and unintelligible; and since that time they have never been considered as of any weight among the Grecian states. Except in the war of Troy, the Cretans took no interest in the general affairs of Greece, nor do they seem to have been influenced by the many memorable events that were transacted in that country.

The original inhabitants of this island, according to the traditions preserved by Diodorus Siculus, were the Idæan Dactyli, who are supposed by some authors to have come from Mount Ida in Phrygia. They had also the name of Curetes, says Strabo, from their being entrusted with the care of Jupiter when an infant; and are said to have discovered the use of fire, and the art of working metals. They also taught men to dwell in houses, instead of the forests and caverns of the mountains; and to tame wild animals, and make them subservient to their wants. They instructed them in the use of the bow and the sword, and were the inventors of military dances. But the most famous were the Titans, who, according to ancient fable, were descended from Uranus and Terra, or, as some say, from one of the Curetes and Titæa, from whom they derived their name. Many of them were renowned for their wisdom and warlike achievements; and from them sprung a race of gods, goddesses, and heroes, an account of whose virtues and crimes constitute almost the whole of the Grecian mythology; or, what is more properly termed by some, the fabulous history of Crete. But whether any of these were the aborigines of the island, or whether Crete had any other inhabitants distinct from them, has not been decided by historians. Indeed, the whole seems to be little better than merely matter of conjecture; and Strabo, after a learned disquisition on the inhabitants of Crete, says, "I am not fond of fables, yet I have entered into a long detail of these, because they have a relation to theology."* However this may be, we are told that they were in after ages called Eteo-Cretans, to distinguish them from foreigners, who, invited by the fertility of the soil and

* Strabo, lib. x.

Crete.

the beauty of the climate, had settled here from all parts of the Grecian continent. Homer, in the Odyssey, enumerates four distinct nations inhabiting Crete besides the natives, all using different dialects, and all apparently free:

> There is a land amid the sable flood
> Called Crete; fair, fruitful, circled by the sea,
> Numerous are her inhabitants, a race
> Not to be summ'd, and ninety towns she boasts.
> Diverse their language is; Achaians some,
> And some indigenous are; Cydonians there,
> Crest-shaking Dorians, and Pelasgians dwell.
>
> Cowper's *Homer's Odyssey.*

According to Eusebius, the first king of the island was called Cres, from whom it received its name. He is said to have been one of the Curetes, and was the author of many useful discoveries, which contributed to the happiness of his people. Of his successors, however, little is known. Their names and their actions are equally lost in allegory; and it would be but unprofitable labour to attempt to draw them from their obscurity. Rhadamanthus and Minos alone deserve to be named; the former as being the first legislator of the Cretans, and as having laid the foundation of their admirable polity; and the other as having many ages after raised the superstructure with such wisdom and success.

The system of laws, of which they are supposed to have been the authors, are well-known through the fame of Sparta; and while the history of the Cretans has been lost, a general account of their polity has been handed down to us by the most respectable authorities. It is considered as the general fountain of Grecian jurisprudence and legislation; and, according to Plato, "was founded upon those solid principles which cannot but render the people who are subject to them flourishing and happy." † The Cretan laws had all a reference to war. To cultivate among his subjects a spirit of unanimity and patriotism, and to inspire them with a love of liberty and military glory, seem to have been the principal objects of the legislator. Courage and noble actions were the only road to honour, and vice was invariably stigmatised with hatred and disgrace. It was not, however, by a multitude of legal enactments, or by the arm of power, that Minos attempted to accomplish his purpose. He had too just a knowledge of the human heart to suppose that these were sufficient to restrain the heedless impetuosity of youth, or the confirmed depravity of manhood; and he therefore endeavoured, by a wise system of education, to destroy the very knowledge of vice, as an object that was to be shunned and despised, by training the infant mind to the love and the practice of virtue.

The Cretans were divided into two classes; that of the youths who had attained their seventeenth year, and were called *Agetas* (companies), and that of the men of mature age, named *Andreia.* As freemen, they were all considered as equal. A community of meals was established at the public expence, where they all partook of the same diet, and were habituated to sobriety and temperance. There the rich and the poor were seated together. They knew no distinction but that of virtue; and we are told that a woman presided at each table, and publicly distributed the best of every thing to those who had distinguished themselves by their courage in war, or their wisdom in council. This honour from the hand of beauty was greatly prized by all, and excited emulation in every breast, to render themselves worthy of the same reward. When the repast was finished, the old men discussed the affairs of the state, discoursed of the history of their country, celebrated the actions and virtues of their great men, recounted the battles in which they had been engaged, extolled the exploits of the brave, and exhorted the youth to similar deeds. It was in those assemblies that the young men were first inspired with the love of virtue and fame. The Cretan boy, at seven years of age, was admitted into the society of the men: and seated on the ground, and clad in a simple garb, he listened in silence to their conversation and counsels. There the patriot and the hero were depicted in such glowing colours, as excited his youthful admiration. He longed to emulate their conduct; and having the most eminent examples of wisdom, justice, and moderation continually before his eyes, he was led to cherish the love of virtue before he had contracted any of the habits of vice. From their infancy the Cretans were inured to deprivations and hardships. They were accustomed to be content with little, to suffer hunger and thirst, and to disregard the rigour of the seasons—to climb mountains and precipices, to bear with resolution the blows or wounds they might receive in the gymnastic exercises; and to make a dexterous use of the bow, the sling, and the sword. They were also taught to commit to memory, and to sing to a particular air, the laws of Minos, which were written in verse, and to repeat hymns and poems in praise of their heroes, or in honour of their gods. At seventeen they were received into the class of the youths, whose exercises were more difficult and severe. They now employed themselves in running, wrestling, and fighting in mock combat, while martial airs were played upon the lyre, to which they were obliged to keep time. These combats, according to Strabo, ‡ were not without danger, as they often made use of iron weapons. But the most common exercise, and in which they were most ambitious to excel, was the Pyrrhic dance. The dancers wore the warlike dress, which consisted of a light jacket that descended to the knee, and was fastened with a girdle that went twice round the waist; and completely armed, they imitated various military evolutions to the sound of instruments. This exercise, which was strictly enjoined by the laws, they considered almost as dishonourable to neglect as to quit their post in the day of battle.

When their young men had completed their education, and had attained the proper age, they were received among the Andreia, by which they became entitled to vote in the national assemblies, and might be chosen to any employment of the state. At this period they were obliged to marry; and even this institution was regulated by the laws. The Cretan married not for himself, but for the state. His bride was chosen by the magistrate, who was guided entirely by a reference to the security of the nation. The stout and handsome youths were joined to young women who resembled them in constitution and figure, without any regard to passion, opulence, or poverty, but merely that a robust race might be produced, that would defend and do honour to their country. Thus by making every institu-

† Plato *de Legibus*, lib. i.

‡ Strabo, lib. x.

tion have a relation to war, a nation of soldiers was formed, all exercised and expert in the use of arms, and capable of defending their property and independence. They were particularly distinguished for their skill in archery; and "the arrows of Gortyna," (a city of Crete) says Claudian, "when happily directed, carry certain wounds, and never miss their aim." Crete at last became so famous among the Grecian states, that it was considered as the best school for learning the military art; and many foreigners resorted thither for that purpose. "Philopœmon," says Plutarch, "being ardently desirous of acquiring knowledge in the profession of arms, embarked for Crete; where having exercised himself among that warlike people, well versed in every military art, and accustomed to lead a frugal and austere life, he returned to the Achæans, and so much distinguished himself by the knowledge he had acquired, that he was appointed commander of the horse."

Minos has been greatly blamed for making war the principal object of his institutions. But it should be remembered, that as he considered liberty to be the best foundation of a nation's happiness, it was necessary that his subjects should be formed capable of maintaining it against every opponent; and it may be observed, that though the system of his laws throughout breathe a martial spirit, yet no prince could be more averse to foreign conquest. Unprovoked warfare, he considered as a system of violence and injustice, which, instead of aggrandising or promoting the happiness of the victorious nation, tended rather to enfeeble it, by wasting its resources and corrupting its morals. Minos, therefore, endeavoured to keep his people continually employed in gymnastic exercises, in the pleasures of the chace, and in public shows; and thus by banishing idleness, he prevented the wish of seeking imaginary glory by foreign conquest. But in the midst of warlike exercises and athletic amusements, the fine arts were not forgotten; but appear rather to have been encouraged and cultivated with great success. Ptolemy* says, the Cretans were even more anxious to cultivate their minds, than to exercise their bodies; and they displayed their munificence to Homer, by giving him a thousand crowns. Thales of Gortyna, the instructor of Lycurgus, was an eminent philosopher and poet; and so great was the effect of his poetry, as we learn from Plutarch,† that when exhorting the people to unanimity, they found their understandings, hearts, and ears, equally persuaded and charmed; and enamoured with the blessings of peace, which he painted in the most lively colours, gradually suffered their animosity to subside. The poet Epimenides, who was so highly esteemed at Athens in the time of Solon, was likewise a Cretan, as were also Ctesiphon, and his son Metagenes, who displayed such admirable skill in building the celebrated temple of Diana at Ephesus. The Cretans regularly frequented the solemnities of Greece, and some of them are immortalized by Pindar‡ as victors in the Olympic, Nemean, and Pythian games.

Minos, like many other ancient lawgivers, pretended that his laws were not the dictates of men, but the suggestions of the Deity, and consequently ought to be received with the utmost submission and respect. He often retired into a cave in Mount Ida, where he boasted of having familiar conversations with Jupiter; and one of his institutions, which Plato considered as the most admirable, was, that young men were not to indulge an indiscreet curiosity respecting the laws; nor examine whether he did right or wrong to enact them, but were to obey them because they proceeded from the gods. If any defects should be observed in them by the old men, they were commanded to address themselves to a magistrate, or to discuss the subject with their equals; but never in the presence of young people.

It is, however, rather a reproach to this wise legislator, who in his institutions studied so much the happiness of his subjects, and put such a high value upon liberty, that while the Cretans lived in honourable freedom, a larger portion of mankind was for their sakes doomed to irredeemable slavery. All the labours of agriculture were performed by slaves and mercenaries, who were obliged to pay a certain annual tribute to their masters, from which were first deducted the sums necessary for the exigencies of the state. They were called *Periœci*, "apparently," says Mr Rollin, "because they were taken from the neighbouring people whom Minos had subdued." But Mr Mitford is of a different opinion, and says, that "it is difficult to account for the first establishment of such a system, but upon the supposition that an Egyptian or Phœnician colony, seizing the lands, like the Spaniards in the West India islands, deprived the inhabitants of arms, and compelled them to labour." We are assured, however, that they were treated with mildness and humanity; for it was an ancient custom in Crete, which was afterwards followed by the Romans, that, at the feast of Mercury, the masters waited upon their slaves at table, and rendered them the same service as they received from them the rest of the year;—"precious remains and traces of the primitive world," says M. Rollin, "in which all men were equal, that seemed to inform the masters, that their servants were of the same condition with themselves, and that to treat them with cruelty or pride, was to renounce humanity."

The monarchical form of government in Crete after the Trojan war, gave place to a republic. Idomeneus the grandson of Minos, who, together with his cousin Merion, conducted eighty ships to the siege of Troy, was probably the last of its lawful kings. At his departure, he is said to have committed the government to Leucus his adopted son, with the promise of his daughter Clisitheia in marriage, if he ruled with wisdom until his return. But Leucus, taking advantage of his long absence, seized upon the throne, after having murdered Queen Mida and her daughter, as the only impediments to his advancement; and when Idomeneus landed in Crete after the destruction of Troy, the usurper, at the head of his partizans, compelled him to return to his ships.§ It is probable, however, that Leucus did not long enjoy his exaltation, for soon after the flight of Idomeneus, we find the monarchy at an end. A republic succeeded, which consisted of ten magistrates and thirty senators. The magistrates held their office only for one year, and were elected in an as-

* Ptolem. *in Tetrab.* lib. ii. † *In Vita Lycurgi.* ‡ Ode xii.

§ Servius, *in Eneid*, lib. iii. who is followed by Fenelon, relates the expulsion of Idomeneus in a different manner. He states that the king had vowed, during a violent tempest, that he would sacrifice to Neptune the first head he should meet on his arrival in Crete; and that his son being the first, he slew him, which so enraged the Cretans, that they drove him from his kingdom. Herodotus, lib. vii. says, that he brought the plague with him in his ships, and that Leucus availed himself of this pretext to procure his banishment.

sembly of the people by a plurality of voices. They were called Cosmi, and had the management of the most important public business, and also the command of the armies in time of war, with absolute power, but were liable to be called to an account for their conduct at the expiry of their authority. The senators were chosen from among those who had passed the office of cosmi, and retained their dignity for life. To them were submitted all state affairs; but nothing was finally determined upon without receiving the approbation of the people. To provide for the expenses of the state, every citizen was obliged to bring into the common stock the tenth part of his revenues. Part of this was applied to the uses of religion and the salaries of the magistrates, and the rest allotted for the public meals. So that all the inhabitants were fed at the expence and in the name of the republic. This form of government was highly extolled by Plato. "The republic," says he, "which approaches too near to a monarchy, and that which admits too unrestrained a liberty, are equally remote from the just medium. O Cretans! O Lacedæmonians! ye have avoided these two rocks, and established your states on the most solid foundation." *De Legibus*, lib. iii.

The republican form of government continued in Crete as long as it remained a distinct nation; and the laws of Minos subsisted in all their vigour in the time of Plato, more than nine hundred years after their first establishment. But though the Cretans retained their freedom, and were so far true to their laws as never to attempt foreign conquest, yet they were continually distracted by internal dissensions. Many of its principal cities had early formed themselves into so many independent republics, who were jealous of each other, and constantly at war. Of these, the most powerful were Cydon, Cnossus, and Gortyna. The two latter, sometimes at variance with each other, wasted the flower of their youth in unavailing contests, and sometimes in alliance attempted to subjugate the neighbouring cities. Cydon alone opposed a determined resistance to their ambition; and, after the greater part of the island had submitted to their power, successfully withstood their united forces. By one of their laws, however, the Cretans were enjoined to unite all their strength whenever a foreign power should attempt a descent upon their coast; and it has been remarked, that they never agreed but when they went to beat off a common enemy. On such occasions, all private animosities were suspended; and being convinced, that victory depended upon the unanimity of their troops, they magnificently adorned the most beautiful young men of the army, and made them sacrifice to friendship before they engaged in battle. In this manner, the republic of Crete had maintained her liberty for ten centuries against every foreign invader. The manners of the Cretans, however, had greatly degenerated from their ancient probity and simplicity. The love of justice had given place to that of gain; and knavery and piracy had become their only occupations. Their character, indeed, had become proverbially infamous, and Κρῆς πρὸς Ἀιγινητην, had nearly the same import as our "set a thief to catch a thief." But the Romans were now extending their conquests over the world; and the Cretans having been accused of favouring the enemies of Rome in the war against Mithridates, their subjugation was determined upon, and war was immediately declared. Marcus Antonius (the father of the triumvir,) was accordingly appointed to conduct an expedition against this island, but he and the greatest part of his fleet were cut off by the Cretan pirates, who hung up their prisoners to the masts, and returned triumphant into their harbours. On the following year, however, Quintus Metellus landed a formidable army on their shores, and after an obstinate and bloody struggle, which continued for three successive years, and in which many of the Romans and the bravest of the Cretan warriors fell, he reduced them to submission, when the laws of Numa were immediately substituted for those of Minos. "From that period to the present time," says M. Savary, "the Cretans have ceased to be a nation, and have gradually lost their courage, their virtues, their sciences, and their arts. So true is it that man is born for liberty, that, deprived of this support, which he has received from nature to sustain his weakness, his genius expires, and his courage languishes, till he sinks to the lowest point of degradation."

The island of Crete was celebrated in ancient times as containing a hundred cities, whence it was called *Hecatompolis*. Forty, however, are only mentioned by Ptolemy; and of these the most distinguished were Cydon, Cnossus, Gortyna, Lyctos, Hiera-petra, Eleuthera, Præsos, Rithymna, Heraclea, Apteron, and Arcadia. See *Ancient Universal History*, vol. viii. p. 212; Rollin's *Ancient History*, vol. v. p. 204; Mitford's *History of Greece*, vol. i. p. 13—176; Savary's *Letters on Greece*, p. 144, &c.; Sabbathier's *Institutions, Manners*, &c. *of Ancient Nations*, vol. i. p. 235. CRETINS. See COMPLEXION.

CREWKERNE, a market town of England, in Somersetshire, is situated in a pleasant wooded valley, on the branches of the rivers Parrot and Axe. The town consists of five principal streets, the houses in which are old and irregular, and its chief buildings are the church, the market house, two alms houses, and two charity schools. The church is an elegant and highly ornamented Gothic structure. It has a body and transept, with a handsome embattled tower sustained by huge pillars. Behind the altar is a room which was formerly a confessional, but is now used as a chancel house. It has a door on each side for the ingress and egress of the penitents, and over the entrance door is a swine, to denote the polluted state of the sinner before his confession, and over the other door are two pigeons, emblematical of the purity with which they go out. The market house, which is large, stands in the centre of the town. It has some manufactures of sailcloth, stockings, dowlass, and girt-web.

In 1811, the town and parish contained,

Houses,	589
Families,	618
Ditto employed in trade and manufactures,	308
Ditto in agriculture,	281
Total population in 1811,	3021

See Collinson's *History of Somersetshire*. (*j*)

CRICHTON, JAMES, a celebrated Scotch author, who, from the extraordinary nature both of his mental and corporeal endowments, obtained the name of the *Admirable* Crichton. He was born in the year 1551, or, according to some, in August 1560, and was descended from respectable parents, who resided in the county of Perth. After receiving his grammatical education in the town of Perth, he was sent to St Andrew's to study philosophy, in which he made rapid progress, under the able direction of Rutherford, Buchanan, Hepburn, and Robertson; and before he had reached his

Crichton.

twentieth year, he made himself master of the sciences of the times, he was able to write and to speak ten different languages, and had attained the greatest skill in the more showy accomplishments of riding, dancing, singing, and playing upon musical instruments.

Having thus completed his education, Crichton set out upon his travels, and paid his first visit to the French metropolis. Conscious of the superiority of his attainments, and eager to display them to the world, he publicly challenged all the celebrated men in Paris to dispute with him in the college of Navarre that day six weeks, at nine o'clock in the morning, when he should answer any question in the arts and sciences, either in prose or in verse, and in any of 12 languages, viz. the Hebrew, Arabic, Syriac, Greek, Latin, French, Italian, English, Spanish, Dutch, Flemish, and Sclavonian. During this interval of six weeks, while his antagonists were preparing for the contest, Crichton amused himself either in hunting, hawking, tilting, &c. or spent his time at balls and concerts; and yet, when the day arrived, he acquitted himself to the astonishment of his auditors, in a disputation which lasted from nine o'clock in the morning till six at night. The president of the assembly then rose from his chair, and, attended by four professors of the university, presented Crichton with a diamond ring, and a purse full of gold, in token of their admiration and esteem. On the following day he attended a match of tilting at the Louvre, and, in presence of a brilliant assembly, he carried off the ring 15 times in succession.

From Paris, Crichton went to Rome, where he exhibited himself, with equal success and applause, before the Pope and the most distinguished characters in that renowned metropolis. *

His next exhibition was at Venice, about the year 1580, where he conciliated the affections of the people by a Latin poem in praise of the city, which he presented to Aldus Manutius, and other Venetian literati. He made a brilliant speech before the Doge, and sustained disputations on various subjects with his usual success. As soon as he had recovered from an illness with which he was here attacked, and which lasted five months, he set out for Padua, and on the 14th of March 1581, he disputed with the most celebrated professors in that university, and particularly exposed the errors of the Aristotelian philosophy. The fame of this exhibition was so widely extended, that he was earnestly solicited to repeat the performance by numbers who were not able to attend before. Manutius informs us, that this second display never took place; but if we believe Imperialis, who speaks on the authority of his father who was present, Crichton did make his appearance, and disputed with Archangelus Mercenarius, who had the reputation of being a profound philosopher. In consequence of some attempts to detract from his merits, Crichton again offered to display his powers in the refutation of Aristotle and his followers, and on other controversial subjects. The disputations which took place on this occasion are said to have lasted three days, and Crichton is reported to have sustained his part with such readiness and ability, as to have extorted acclamations from the whole assembly.

Hitherto Crichton was chiefly called upon to exhibit his mental qualifications; but at Mantua, which he next visited, he had to encounter an enemy more formidable than any of the champions of Aristotle. A gladiator, who had overcome the most celebrated fencers in Europe, was living under the protection of the Duke of Mantua, and had already slain three individuals who had accepted of his challenge. As soon as Crichton heard of this prodigy, he offered to fight him for 1500 pistoles, and though the Duke remonstrated with him on the danger to which he exposed himself, and was unwilling that society should lose such an ornament, he at last agreed to the proposal, and appointed a day when the champions should fight in presence of the court. The skill and cool intrepidity of Crichton were an overmatch for the eager impetuosity of the Italian, who was at last thrice run through the body. The prize of 1500 pistoles, which the victor thus acquired, was generously divided among the widows of the three individuals whom the gladiator had slain.

Crichton.

Astonished at the qualities both of mind and body which he had witnessed, the Duke of Mantua chose Crichton as preceptor to his son Vincentio di Gonzaga; and out of gratitude for this appointment, Crichton is said to have written a comedy satirizing the various professions in which men are engaged, and to have supported 15 characters in the representation of his own play.

During the time of the Carnival, when Crichton was playing on his guitar in the evening through the streets of Mantua, he was assailed by several persons in masks. Having repelled all their attacks, he disarmed their leader, who pulled off his mask, and begged his life as being the prince, his pupil. Upon this discovery Crichton fell upon his knees, apologised for his mistake, and assured the prince that if he had any design upon his life, he might take it when he pleased. He then took his own sword by the point, and presented it to the prince, who barbarously run him through the heart. This event is said to have happened in July 1582 or 1583.

Such are the wonderful feats which our countryman is said to have performed; and if we were even so credulous as to believe them all, we should not be disposed to rank him among those men who have done honour to their country by advancing the interests of literature or science. Various circumstances, however, which it would be unprofitable to enumerate, concur in throwing a suspicion over the whole of Crichton's exploits; and we think that we are sufficiently liberal in our praise when we reduce his pretensions to those of an accomplished scholar. Versed in the ancient and modern languages, which he retained by the aid of a powerful memory, and possessed of great fluency of utterance, and confidence in his own powers, it was no difficult matter to astonish the learned pedants of the 16th century; while the elegance of his person and manners, and his other dazzling accomplishments, captivated the affections of the gay crowd, who are the dispensers of contemporary fame. The award of posterity, however, generally reduces the extravagant encomiums with which living merit is too often flattered; and he who during his lifetime has been elevated with the praises of fashionable admirers, often sinks into oblivion with the dull crowd by whom they were conferred. National partiality, and individual affection, may avert for a while the extinction of a dying name; but the impartiality of

* Boccalini, who was at Rome when Crichton visited it, states, that having been ridiculed in a pasquinade, as an empiric, he left the city in disgust.

Crichton, Crimea.

a new generation cherishes the memory only of those who have enriched literature and science with their genius, or who have enlarged the comfort and happiness of their species. The reputation of the Admirable Crichton is, we fear, of this perishable kind. The works which he has left behind him, and which have been long forgotten, exhibit no marks either of taste or genius. His accomplishments as a scholar have already received their full reward, and impartial justice has no demands upon posterity for a prolongation of his fame. The following is a list of his works: 1. *Odæ ad Laurentium Massam plures.* 2. *Laudes Patavinæ, Carmen extempore effusum, cùm in Jacobi Aloysii Cornelii domo experimentum ingenii coram tota Academiæ frequentia, non sine multorum stupore, faceret.* 3. *Ignorationis Laudatio, extemporale Thema ibidem redditum, post sex horarum disputationes.* 4. *De Appulsu suo Venetiis.* 5. *Odæ ad Aldum Manutium.* 6. *Epistolæ ad Diversos.* 7. *Præfationes solemnes in omnes Scientias sacras et profanas.* 8. *Judicium de Philosophis.* 9. *Errores Aristotelis.* 10. *Arma an Literæ Præstant, Contraversia oratoria.* 11. *Refutatio Mathematicorum.* And, 12. A Comedy in the Italian language. Several of these poems are published in the *Biographia Britannica,* to which we must refer our readers for farther information respecting the subject of this article. (*w*)

CRIEFF. See PERTHSHIRE.

CRIMEA, anciently *Taurica Chersonesus,* a peninsular province of European Russia of recent acquisition, in the new government of Taurida, formerly called *Crim Tartary.* The name of Crim, or the Crimea, has been by some derived from the ancient *Cimmerii,* but is supposed by John Reinhold Forster to have originated from the city of *Krim,* now called Stara-crim, or Eskikyrim, signifying the old citadel, denominated *Cimmerium* by the ancients. In some middle age travels, the Crimea is denominated the island of Caffa.

Name.

Situation and extent.

This peninsula is situated between the latitudes of 44° 40′ and 46° 5′, both N. and the longitudes of 32° 45′ and 36° 30′, both E. reckoning from Greenwich. It is of an irregular rhomboid or lozenge shape, lengthened out to the west, and more especially to the east, every where surrounded by the waters of the Black Sea and sea of Azof, except at its northern angle, where it joins the continent of Europe by the isthmus of Precop, otherwise Perecop, and Or-Capi, only four miles wide. From this isthmus in the north to its most southern cape or promontory, denominated *Krin Metopon* by the ancient Greeks, the extent is 124 English miles; and measuring from the western cape to the eastern promontory of Yenikale, it extends 208 miles from W. by N. to E. by S. The entire area, therefore, making every allowance for the irregularity of its shores, cannot be less than 5600 square miles, or 3,584,000 statute English acres; but the far greater proportion of the surface consists of extensive *steppes,* or comparatively desert plains.

Boundaries.

Beginning on the north at the isthmus, the north-western side of the Crimea is bounded by the gulf of Perecop, a large bay of the Black Sea or Euxine. The north-east side, from the isthmus eastwards to opposite Yenitche in the continental desert of the Nogays, is bounded by the Sivash, or Mud Sea, an extremely irregular and shallow gulf of the *Palus Mæotis,* or sea of Azof, called also Ischaback-Denghissi, and sea of Tabachi, or of Zabachi. This gulf of Sivash was denominated *Putris Palus,* or Putrid Gulf, by the ancients. It also covers most of the eastern side of the Crimea, cutting deep into its shores by many irregular shallow bays and salt marshes; and is itself singularly bounded and divided from the sea of Azof on the east, by the peninsula, or long narrow stripe of Arabat, which projects from the Crimea in the S. E. not exceeding a mile or a mile and a half in breadth, but extending north, or rather north-by-west, for seventy miles, and is only separated from the continent at Yenitche by a strait of a mile and a half broad.

Below, or to the south of this singular spit of land, a considerable projection of the Crimea, called the promontory or peninsula of Kertsch, anciently the kingdom of *Bosphorus,* extends to the east, having the sea of Azof on the north, the Black Sea on the south, and the Straits of Yenikale or Taman, anciently the Cimmerian Bosphorus, on the east, which divides it from the Isle of Taman, beyond which is Kuban Tartary. The whole southern and western coasts of the Crimea are washed by the Euxine or Black Sea.

Divisions.

This province may be divided into the Crimea Proper, the eastern subordinate peninsula of Kertsch, and the Island of Taman. The climate is subject to considerable variation, the winters being sometimes extremely severe, with intense and long-continued frost, especially in the extensive *steppes* or northern plain, which is much exposed to the north-east winds, while the season of spring is pleasant and moderate, with cool nights and serene weather. The summer is often excessively hot, and droughts of considerable endurance frequently prevail. The autumnal season is sultry, moist, and unhealthy.

More than three-fourths of the Crimea Proper, to the north, are occupied by a vast undulated plain, called the Steppes, of varying soil, without trees, being mostly composed of sand, more or less mixed with clay, and affording pasture to numerous flocks belonging to the Nomadic Tartars. This large plain or steppe abounds with salines, or salt lakes and marshes, from which abundance of salt is procured in the dry season, for supplying the inhabitants of the peninsula, and the Nogays, who wander through the steppes on the continent between the Nieper and the Don; as also for the neighbouring governments of Russia, and for Anatolia, Bessarabia, and other countries around the Euxine. So great is the abundance of this salt, which is procured without the trouble of any process, except gathering it from the dried up ponds, that two hundred vessels load with it yearly from the single port of Caffa, besides immense quantities carried inland in waggons. This salt is easily obtained, as the conductors of the immense numbers of *Kibitkas,* that resort to Perecop for this indispensible necessary, have only to drive axle deep into the shallow water, and load as fast as they please, the salt lying in heaps like sand. They are to be seen at this work to the number of hundreds at a time, the driver of each waggon, or kibitka, paying a tax of ten roubles to the crown for his load of salt. It is sent by the Black Sea to Constantinople and the Archipelago, and by land to Poland and all Russia, even as far as Petersburg and Riga. Even in the earliest periods of history, Taurica was, as now, the emporium of this commodity to all the surrounding countries.

Salt.

Soil.

The soil of this extensive flat consists partly of a white sandy clay, and partly of a black vegetable loam, and near the southern hills is mixed with chalk and limestone. It had formerly a great number of Tartar villages, wherever water could be procured for irriga-

Crimea. tion; and for this purpose the Tartars were at great pains to procure water from the distant heights, by means of canals and tunnels of clay below ground, discharging themselves into stone reservoirs, to serve the inhabitants and their cattle, and to water their cultivated land, orchards, and gardens, during the dry season. Since the Russian conquest, the Tartar population has greatly deserted the country, and the Russians have unaccountably suffered the excellent system of canals, tunnels, and reservoirs to fall to ruin, by the most culpable neglect. This comparatively level tract is said to abound in petrifactions, and the remains of marine productions of various kinds; and, though now considerably elevated above the level of the Black Sea, is said to afford strong indications of having once been entirely covered over by the waves, in which case, the Euxine must anciently have been of much greater extent, especially to the northwards. This was the opinion of Pliny, founded upon the authority of more ancient writers, who, in his account of the Chersonesus, has the following passage: " From Carcinitis begins Taurica, once surrounded by the sea, which covered all of its champaign part."

Mountains. The mountainous southern portion of the Crimea extends along the shore of the Black Sea, from Aktiar, or Sevastapol, in the S. W. to Caffa, or Theodosia, in the S. E. The principal ridges extend from east to west, their southern declivities being much steeper than their northern slopes. These hills are chiefly composed of calcareous rocks, covered by a clay soil of some depth and fertility, in some places mingled with gravel and round stones, rendering it particularly suitable for cultivating the vine, while the other parts grow wheat, rye, barley, millet, flax, hemp, and tobacco in considerable luxuriance. Some of these hills are said to have all the appearance of being formed by alluvion, while others bear the marks of having been produced, or altered at least, by the operation of fire; especially two in the subordinate peninsula of Kertsch, which are denominated volcanoes. The most elevated of these mountains are covered with snow till the end of May, and their sides are clothed with extensive forests, yielding excellent ship timber. Some of the summits in this mountainous chain are estimated at 1200 feet above the level of the Euxine, having plains on their tops, partly composed of bare rock, and partly covered by a thick stratum of earth. From Tschadir-daghi, or the Pavilion Mountain, the *Trapezus Mons* of the ancients, the prospect extends almost over the whole peninsula. Many petrifactions are found even on the tops of the mountains, and numerous caverns penetrate their sides, as is usually the case in calcareous districts; and in one of these of vast size ice remains unmelted during the whole year. No traces of metals have hitherto been discovered; but in several places they dig up a species of marle, or rather a kind of fullers earth, which is said to serve all the purposes of soap.

Productions. The lower edges of the hills, and the intermediate vallies, are productive of all kinds of grain, together with flax, hemp, and tobacco, and are beautifully diversified with gardens, orchards, and vineyards; these last more especially in the neighbourhood of Sudak, where they make an excellent wine, resembling champagne in colour, strength, and flavour. In these places, the cultivated soil consists of a thick bed of gray fertile loam resembling potter's earth, mixed with small stones and gravel. This southern tract is beautifully diversified among the mountains, with elevated plains and fine vallies, covered by the richest verdure, and interspersed with almost perpendicular calcareous rocks. Among these, the valley of Baidari, which was given to Prince Potemkin at the Russian conquest, is extolled by all travellers as peculiarly interesting and beautiful. It abounds in fine woods, especially composed of large oaks and walnut trees, interspersed with open and well cultivated fields, gardens, and orchards. In one place, an oak is mentioned as measuring thirty feet in circumference, six feet from the ground. The celebrated professor and traveller Pallas, who has enumerated a great number of plants indigenous in the Crimea, describes the vegetation of this country as being extremely luxuriant. The *crambe orientalis*, or wild horse radish, is peculiarly abundant in that part of the country which lies between the rivers Salgir and Karasu, and is often thicker than a man's arm. This is extolled by Lady Craven, as the strongest and best flavoured horse radish she ever tasted.

Locusts. The Crimea, at certain seasons, is much infested by locusts of two species, the *gryllus tartaricus* and *migratorius*, which often do much injury, by eating up the whole vegetable productions wherever they settle. The fields, the vineyards, gardens, and pastures, are all laid waste; and sometimes the only appearance left upon the naked soil is their putrefying bodies, the stench of which is enough to breed a pestilence. The large black tarantula is found of a fearful size. The phalangium arachnoides, also, an insect allied to the spider, whose bite is said sometimes to prove fatal. Centipedes likewise, the *Scolopendra morsitans* of the naturalists, are very common; and scorpions are found in the mountains.

Rivers. The principal river in the Crimea is the Salgir, with its feeders the Great and Little Karasu, or black-waters; besides which it has many smaller streams, as the Alma, Belbeck, or Kabarta, Byuk, or Kasikly-useen, Aithoder, Balganack, Badraka, Katsha, Dasta-su, Burultsha, &c. all rapid and dangerous torrents after heavy rains, but mostly rivulets only in the dry season.

Ancient kingdom of Bosphorus. The eastern promontory, or subordinate peninsula of Kertsch, anciently the kingdom of Bosphorus, differs considerably in appearance and soil from the rest of the Crimea. It measures about eighty-four English miles from west to east, by about twenty-four at a medium from north to south. The isthmus by which it is connected with Crimea Proper, of about ten miles broad, is a level plain, to the east of which the country rises into gentle eminences; and at the eastern end near Kertsch and Yenikale there are hills of some elevation. The shores of the Euxine, and Sea of Azof, all around this peninsula, are high, steep, and of difficult access. Between the hills there are several salt lakes, some of which are separated from each other by beds composed of shells and sea sand. The few and scanty rivulets of this peninsula are dry in summer; and, although there are many springs of excellent water among the hills, that which is procured by digging pit wells in the lower grounds is mostly brackish. Though destitute of natural wood, this peninsula has abundance of fruit trees in its gardens and orchards; and the soil in general, except around the saline lakes and salt marshes, is fertile and productive.

The singular stripe or spit of land, stretching from Arabat towards Yenitche, and separating the Mud Sea, Sivash, or Putrid Gulf, from the sea of Azof, formerly mentioned, is composed of shells and sand, and is most-

Crimea. ly level, with a few small eminences, being covered with rich pasture. Near an elevated sandy promontory projecting into the sea, called Kamesch-bourne, great numbers of petrified shells are found, as also a singular mineral, said to be native prussiate of iron, or Prussian blue. Salt springs are found in the hills near Yenikale, as also a spring of petroleum or rock oil. Also, on the summit of a hill in this peninsula, there is a marsh containing bitter salt water, emitting a disagreeable smell, and resting upon a black sulphureous slimy bottom; and on the leaves and stems of the vegetables growing around this marsh, liver of sulphur, sulphuret perhaps of soda, is found deposited.

Isle of Taman. The island of Taman, though not actually a part of the Crimea, is included in the same government. It is separated from the peninsula of Kertsch by the straits of Yenikale or Taman, anciently the Cimmerian Bosphorus, which bounds it on the west. The north side of this island is washed by the sea of Azof, and the south side by the Black sea, while the eastern end is separated by an irregular congeries of small saline lakes, with narrow interposed isthmuses, from Kuban Tartary. The breadth of the straits of Yenikale is from seven to twelve miles. The length of this island from west to east is about forty miles, and its breadth from north to south twenty-six. Its surface is considerably elevated above the surrounding waves, the shores being generally upwards of seventy feet high, and very steep; while at its western extremity there are several hills, two of which are said to be volcanic. The soil is in general a sandy loam, but is of clay in some places; the sloping sides of the hills and intermediate vallies being fertile, and well cultivated in some places. Though this island does not naturally produce either trees or shrubs, yet, in the vicinity of Taman, at its western extremity, there are many large orchards, in which fruit trees have long flourished in great luxuriance and productiveness. It has many springs of fresh water, but no running streams. In some places there are saline pools and salt springs, containing petroleum; and the interior of the island is said to abound in a resinous combustible substance, supposed to be composed of, or impregnated with, mineral oil or petroleum, that has been distilled or sublimed by means of subterraneous fire. Before the town of Taman there is a spacious bay of the same name, the *phanagoria* of the ancients, but too shallow to allow of being navigated by large vessels. The interior of the island is the most elevated and fertile; but some districts are represented as unhealthy, owing to thick fogs, the humidity of the soil, and the bad quality of the water.

A mud volcano. There is a volcano in the island of Taman, about 27 miles east from the fortress of that name, called Coocoobo by the Tartars, and Prekla, signifying hell, by the Tchernomorski, the present inhabitants of the country. Its eruptions, though accompanied by fire and smoke, have not hitherto been followed by any appearance of lava, its disjectitions consisting of vast quantities of viscous mud.

Geology. The following short account of the geology of the Crimea, from the pen of the celebrated Pallas, is all that our limits can afford. "In a country, containing mountains of such elevation, that snow and ice remain in some spots throughout the whole year, and which also is almost insulated, one would expect, conformable with the general laws of nature, to find the three different orders of mountains: The *primitive* or granitic mountains, as the center of elevation; the *secondary* or schistose; and the *tertiary*, composed of horizontal or flat strata, mixed with petrifactions; or at least, as in Sicily, a volcanic central nucleus, having secondary and tertiary stratifications around its skirts; but in Taurida neither of these arrangements are to be found, which are observed in all other mountainous countries. Throughout the entire maritime range of the Alpine chain of Taurida, nothing is to be seen but secondary strata of the latest order or formation, all inclined to the horizon at an angle more or less approaching to 45°, and all less or more parallel to each other, and in a direction between the south-east and north-west. All the strata, therefore, are cut off or laid open in the direction of the coast, and are all distinctly seen upon the maritime steep slopes of the mountains, like the leaves in a book, or the volumes in a library." The exterior or upper strata, consist of calcareous matter of very recent formation. The highest of the mountains afford no trace either of primitive granite, or of any regular schistose deposite, but are entirely calcareous. Beneath those enormous calcareous masses, pillars of marble, trap, clay, common limestone, and schistus, appear in parallel and almost vertical veins or strata, alternating with each other, and leaning from north-west to south-east, and their precipitous elevation in some places from the sea, bespeaks a corresponding depth below the surface of the water. Among the extraneous fossils of the Crimea, the *lapis nummularius* may be mentioned, which is there very common, though rare every where else.

Population. The population of the Crimea is said to have formerly amounted to a million and a half, but it was much diminished by the wars between the Turks and Russians; and in 1793, was only estimated at 157,125. Besides great numbers of Tartars of different descriptions, it was formerly inhabited by Turks, Greeks, and Armenians, especially in the towns along the coast; but since the Russian conquest, the Turks of course have all quitted the country. Many of the Tartars also have removed with their families and flocks to the steppes or deserts of the continent; and even the Armenians are said to have mostly abandoned the country, or rather to have been constrained by the Russians to emigrate.

According to the celebrated Pallas, the Tartars of the Crimea may be divided into three classes. The first are the Nogays, the least mixed of the Mongolian race or Moguls, who devote their attention to agriculture and the rearing of cattle. A second race of Tartars occupied the steppes or plain, from the edge of the hilly country to the isthmus of Perecop, who also resembled the Moguls. The third class, inhabiting the southern vallies of the mountains, is described as a mixed race, having a distinct physiognomy, with stronger beards and lighter hair than the other two, and were entirely stationary, devoting their attention to agriculture, and especially to the cultivation of hemp and tobacco.

The young Tartars of the plain, particularly those belonging to noble and rich families, dress nearly like the Circassians and the Cossacks, the sleeves of their coats being short and open; while the old Tartar nobles, and the common people, wear close sleeves. The old men allow their beards to grow, while young people wear only whiskers. On their heads they wear high caps, and their legs are covered with half boots. The Tartar women are generally small sized, wearing drawers, or long wide trowsers, shirts open before, an open gown of silk, with long narrow ornamented sleeves, and above all a great coat with short sleeves, and a belt round the waist. They plait their hair, which is generally covered by a small cap, or by a piece of linen crossed under the chin. They paint the nails of their hands and feet red, and stain their eye-brows black. A long narrow piece of cloth hangs down behind from the top of their heads, while tresses of hair, stained of a brown red colour, hang down on their cheeks. When out of their tents, they usually cover their faces with a fine veil of white linen. Their food consists of mutton and lamb, boiled or roasted, together with eggs, milk, butter, fruits, and vegetables, and the Nogays eat horse flesh. Their ordinary drink is water, and a kind of beer called Busa. They have few manufactures, the most noted being of leather, dressed and stained like what is usually called Morocco. The principal exports of the Crimea are wheat, salt, leather, soda, butter, fish, cordage, honey, and wax; and the chief imports are stuffs of silk and of cotton.

Towns.

There are a few indifferently built towns in the Crimea, and many villages. Perecop, or Or-capi, anciently *Taphræ*, situated on the middle of the isthmus of that name, is chiefly remarkable for its military lines for the defence of the isthmus against the roaming tribes of Scythia, consisting of a rampart and ditch, now fallen to ruin. It had been originally fortified by a Spartan general, in the fourth century before our Saviour; and the defences were restored by the Emperor Justinian, in the sixth century of the Christian era. This fortification was called *Neon Teichos*, or the new wall, by the Greeks. At Perecop there are only a very few houses, inhabited by the post-master and custom-house officers, and a small barrack. The famous wall is of earth, and very high, with an immense ditch, stretching in a straight line from sea to sea, without any remains of flanking towers; and the *golden*, or royal gate, as it is called, is narrow, and too low for the passage of an English waggon. Perecop, the Russian name of this place, means the trench or fortification; and Or-Capi, the Tartar appellation, signifies the gate.

For an account of BATCHESERAI, formerly the Tartar capital, see that article.—Before the Russian conquest, almost all the merchants and shopkeepers of the Crimea were Armenians, 75,000 of whom emigrated, or rather were driven out by the Russians, and all except about 7000 perished, from cold and hunger, in the *steppes* on the west side of the Sea of Azof. Of the present inhabitants of Batcheserai, above 1100 are Jews, of the sect of *Karaïtes*, who reject the traditions of the Talmud and Targum. About three miles from this Tartar capital is Dschoufout-Kale, or the fortress of the Jews, containing 200 houses, and about 1200 inhabitants. This sect of the Jews have the most unexceptionable character, and their honesty in the Crimea is even proverbial, their promises being considered as equivalent to a bond.

After the Russian conquest, the seat of government was removed to Akmetshet, or Sympheropol, the former being the Tartar, and the latter the modern Greek name; and it is reported, that, on this occasion, Prince Potemkin tossed up with his generals for the choice of the new capital. This is a small town about 20 miles from Batcheserai, situated upon an elevated plain, almost surrounded at irregular distances by calcareous hills, and having the principal stream of the Salgir to the east. The old Tartar town consists of a few narrow unpaved streets; and the new town, built by the Russians, is composed only of a few houses, already going to ruin.

Aktiar, or Sevastopol, in the south west angle of the peninsula, or what was anciently called the Heracleotic, or Minor Chersonesus, is built in the form of an amphitheatre, at the bottom of an excellent harbour, upon a neck of land, interposed between two bays. This town is composed of parallel streets on a declivity, divided into quarters by transverse streets, and is excellently situated for trade, which is rapidly on the increase. The harbour, which was named *Ctenus* by the ancients, and is now the anchorage of the Russian fleet, extends nearly four miles inland, is only two hundred yards wide at the entrance, which is defended by two forts and several batteries, and is nine or ten fathoms deep. In the neighbourhood of Atkiar, are the ruins of the ancient city of Chersonesus, on a bay now used as a station for vessels performing quarantine. This place was called in the middle ages Sherson and Schurschi, being the *Cherson Trachea* of the ancients, and was founded by the inhabitants of Heraclea, six hundred years before the Christian era. It is also termed in ancient writers Cheroneus or Chersonesus. In the older annals of the Russians it is named Korsun, and was called Karaje-burn by the Turks. This place must be carefully distinguished from modern Cherson on the Dnieper.

To the south-east of this Heracleotic Chersonesus, is the town and bay of Balaclava, the *Portus Symbolorum* of the ancients; and to the westward is a rugged cape, named Aya-Burun, or the Sacred Promontory, on which are the ruins of an ancient temple of Diana. Mankup, a fortress of the Genoese, now in ruins, is situated on the top of a steep rock, about eight miles inland, and E.N.E. from Balaclava.

The country included within the harbour of Aktiar, or Inkerman, called anciently *Ctenus* by Strabo, and the harbour of Balaclava, the *Symbolorum Portus* of the ancients, forms the *Minor*, or *Heracleotic Chersonesus*, which is accurately described by Strabo as a portion of the *Peninsula Major*, or *Taurica Chersonesus*. In this small district stood the three cities of *New* and *Old Chersonesus*, and *Eupatorium*, the temples of Diana, the promontory of Parthenium, celebrated as the scene of the story of Iphigenia, the famous mole of Chersonesus, with numerous ramparts, tombs, canals, and other works mentioned by historians, but which are all now in ruins, and their remains hastening to be annihilated by the Russians. The most remarkable curiosity in this neighbourhood consists of the ruins and caverns of Inkerman, or city of caverns, consisting of numerous chapels, monasteries, cells, sepulchres, &c. hewn out of the solid rock.

Karasu-bazar, or the market-town on the Karasu, is a mean irregular town of about 900 houses, yet has 23 coffee-houses, and 310 shops. The inhabitants of this town still amount to 3700 individuals, young and old of both sexes, including a curious mixture of Tartars, Russians, Greeks, Italians, Armenians, and Jews. Uskut, a populous village among vineyards, not far from the south coast of the peninsula, was anciently named *Athenion*; and a few miles to the eastward, on a steep narrow ridge, are the ruins of an ancient fortress called Tshoban-kalle, or the shepherd's hut, by the Tartars.

Sudak, or Sudagh, formerly Soldadia, Sogdaia, and Sudagra, the Sidegrius of the ancients, situated on a gulf near Cara-kaia, is chiefly remarkable for its beautiful vale, abounding in vineyards, and has the ruins of a Genoese fortress on a rock near the sea. This city rose to such celebrity for its extensive commerce, that all the Greek possessions in the Crimea were denominated Sugdania at one period.

Caffa, or Kaffa, formerly a place of great importance, but now fallen to ruin, has been already described in a separate article. See Caffa.

Kertsch, Kertchy, Cherz, Kars, or Kerez, on a bay in the straits of that name, is a small walled town on a projecting point of land, a few miles from the ruins of the ancient *Panticapæum.* The natives of the Crimea still call the town of Kertsch, and the straits, Vospor, though they write the word Bospor; and all the modern Greeks uniformly pronounce the letter β as our V. This town, though not long since of considerable importance, is now reduced to extreme wretchedness and insignificance. It was the regal seat of the Bosphorian kings, and once the residence of the great Mithridates king of Pontus.

Yenikale is a small town, with a strong fortress commanding the narrowest part of the straits of the Cimmerian Bosphorus, being the *Parthenium* of the ancients. Between this and Kertsch, on the shore of a considerable bay, are the ruins of the ancient city of *Myrmecum.* About four miles from Yenikale, towards the sea of Azof, on a rocky point advancing into the sea, stood an ancient pharos or light-house, said to have been built by Mithridates, and still called by the modern Greeks *Phanari Mitridati,* or the lanthorn of Mithridates.

Taman, on a bay in the island of the same name, anciently called *Phanagoriæ Sinus,* is a fortress of some importance, near which are the ruins of the ancient city of *Phanagoria.* There are several other towns, and many villages, particularly along the southern side of the peninsula, which it is quite unnecessary to particularize.

History. The ancient *Taurica Chersonesus* was so called from its inhabitants, the Tauri or Taurici, a Sarmatian tribe. It was also called *Chersonesus Scythica,* and *Chersonesus Magna,* to distinguish it from the Heracleotic Chersonesus, or Minor. The most anciently known inhabitants were the Cimmerians, a numerous and martial tribe of the Thracians, who long continued to defend this peninsula against the Scythians; but were driven from the plain by their more powerful adversaries, about 665 years before the Christian era, and forced to take refuge in the southern hills, where they maintained their independence under the name of *Tauri,* or mountaineers. About 550 years before Christ, the Greeks began to form colonies on the southern shores of the Taurica, at which time Panticapæum was built by the Milesians, and where they long carried on a flourishing commerce, having reduced the subordinate eastern peninsula, which formed the Greek kingdom of Bosphorus. About 100 years afterwards, the Scythians were almost extirpated by the Sarmates; after which the Tauri, called also Tauro-Scythæ, extended their dominion nearly over the whole peninsula, and pressed so hard upon the Bosphorian kingdom that it submitted, 112 years before the incarnation, to Mithridates, king of Pontus, who subdued the Tauri, and reduced the whole Chersonesus under his dominion. After the ruin of Mithridates by the Romans under Pompey, the kingdom of Bosphorus seems to have subsisted, but dependent upon the Romans, till the commencement of the Christian era, in considerable power and splendour; at which period the Alani drove out the Tauri from the greater Chersonesus, and forced the Bosphorian kings to become tributary.

About 150 years afterwards, the Alani were extirpated or driven out by the Goths, during whose dominion Christianity was first introduced into the Chersonesus, in the reign of the Roman emperors Diocletian and Constantine. The Goths were obliged, in their turn, to give way to the Huns, and took refuge in the mountains, where they defended themselves under several petty kings in strong forts, which were afterwards, by a singular corruption, instead of castles of the Goths, called castles of the Jews. The descendants of the Huns took the name of Aoultziagrians, who led a wandering life in the steppes or plain country of the Crimea, and were in the sequel reduced to subjection by the Khatyares, to whom also the Goths in the mountains, and the Greek cities on the coast, became tributary.

In 840, the emperor Theophilus subjugated the Crimea, the country between the Nieper and the Don, and Kuban Tartary, placing the seat of government at Cherson or Chersonesus. The whole of this country, or at least its steppes or pastures, was occupied by the Khatyares, under the acknowledged supremacy of the Constantinopolitan empire, and from them the flat part of the peninsula had the name of Khat, or Gatyria, corrupted into Gasaria, Chazaria, and Cassaria; the mountainous part being called Gothia from the Goths, and Tsikia from a remaining tribe of the Alani.

In 880, the Khatyrians were driven out by the Kanglians, or Petschenegers. About the year 1050, they had to fly before the Komanes or Comanians, called also Uzes, Butyres, Palatstzes, or Polouzes, to whom also the remaining Goths and Greeks became tributary. About this time, the town of Sougdia or Sugdaya, now Sudack, rose to such eminence by its commerce, that all the Greek possessions in the Crimea received the appellation of Sugdania; and in 1204 refused obedience to the empire of Constantinople. Even at a much later period, when the Turks became masters of the Constantinopolitan empire, there still remained two Greek principalities in the Crimea, one called Theodor, now Inkerman; and the other named Gothia, now Mangoute.

In 1237, the Komanes were subdued by the Mongols or Tartars, after which the Crimea became a province of the western Tartar empire of Kiptschak, the people being governed by princes of the different tribes, and roamed about the plains with their flocks and herds; and now the Greeks and Goths paid tribute to the Mongols. In the beginning of this Tartar empire, a number of Tcher-casses or Circassians established themselves in the western subordinate peninsula, and Kertsch was governed by a prince of that nation, probably taking its name from that tribe.

When the Latins became masters of Constantinople, the Venetians established an important commerce with the Crimea and the island of Taman; in which they were afterwards supplanted by the Genoese, their commercial rivals, who, by permission of the Mongoles, rebuilt Caffa, the ancient Theodosia, which they made their staple, or the centre of their commerce in the Black Sea. They also reduced Sudack and Cembalo, or Portus Symbalorum, now Balaclava. At this period a lucrative trade was carried on with India and China from the Crimea, by means of caravans in two different routes. One from Cathay or northern China across the Amour, and through central Asia, by the north of the Caspian, and Astrakan to Tanna, now Azof, in which the Venetians participated along with the Genoese.

Crimea, Crimes.

The other was across the Caspian by way of Trebizond, Taurus, and Bagdad, to the Persian gulf, and was established at Sevastapol or Atkiar in the Crimea.

In 1441, the Crimea became an independent Tartar monarchy under its own khans of the house of Zingis or Tschinghis; but was soon reduced under subjection to the Turkish empire, by which also the Genoese were expelled from the Crimea about the close of the fifteenth century. The Turks now placed garrisons in the principal cities and fortresses of the Crimea, setting up and deposing the Tartar khans at their pleasure; and, shutting up the entrance into the Black Sea, completely ruined the commerce of the peninsula. The Crimea continued under subjection to the Turks till 1774, when the Empress Catharine II. of Russia, by the peace of Kutschuk-Kainardgi, stipulated for the independence of the Crimea under its own khans. In 1781, a civil war broke out among the Crim Tartars, in which the Russians interposed; and in 1783, Sahim Gheray, the last khan, abdicated his power, which he transferred to Russia, and this acquisition was confirmed by a treaty with the sultan in 1784, since which Taurida has continued to be a province of the Russian empire. The abdicated khan retired into Moldavia, whence he was dragged to Rhodes, where he was assassinated by the Turks in the residence of the French consul, in which he had taken refuge.

Antiquities.

Among the most remarkable antiquities of the Crimea, are the military lines constructed in different parts by its ancient Grecian colonists, to defend their possessions from the depredations of the successive Nomadic tribes, who have infested its steppes in all ages. Besides the lines of Perecop already mentioned, there are vestiges of others for the defence of the Minor Chersonesus, said to have been erected by one of the generals serving under Mithridates the Great. There are also three series of similar field works of great extent, erected by the Bosphorian kings in different ages, to defend their eastern peninsula. It would, however, occupy too much space in this work to give an account of the numerous antiquities still visible in many parts of the Crimea, and of which ample accounts will be found in the works of various travellers, and particularly in he recent travels of Edward Daniel Clarke, LL.D. Part I. chap. xviii.—xxiii. See Tooke's *View of the Russian Empire*; Reully, *Voyage en Crimée*; Pallas, *Travels in the Southern Provinces of Russia;* Lady Craven's *Journey to the Crimea;* and Clarke's *Travels in Europe, Asia, and Africa,* Part First. (KK)

CRIMES, in a legal sense, are certain acts committed in violation of the public law of the country, and punishable by courts of justice. In common usage, the word "crimes" is understood to denote those atrocious offences, which have a more direct tendency to subvert the government or constitution, or to loosen the bonds of society; while the slighter transgressions, which do not so immediately affect the security of the public, are generally comprised under the denomination of *misdemesnors* or *delicts.* The different species of crimes, which fall under the cognizance of our courts of justice, will be found explained under their respective titles. Our object, in this article, is to give a general view of the nature and division of crimes; with a few observations on criminal law, in reference more especially to the institutions of our own country.

The difference between a crime and a civil injury seems to consist principally in this: the latter is only an infringement of the private rights of individuals, considered merely as individuals; whereas the former is a violation of the public rights of the whole community, considered in its social aggregate capacity. Civil injuries, therefore, may be prosecuted and redressed at the instance of the individual injured; but the prosecution of crimes belongs to the community, or to the person in whom the right of the community is vested. By the Roman law, the more atrocious crimes might be prosecuted by any individual member of the community; with us, all crimes are prosecuted at the instance of his majesty, through the medium of the law-officers of the crown. This distinctive character of crimes seems to be but imperfectly understood in the earlier stages of society; all offences being considered rather with a view to the immediate injury done and suffered, than to their consequences in regard to the public security. By the ancient Saxon laws, *weregilds* were allowed to compensate the crime of homicide, according to the degree of the person slain, (see APPEAL); and in England, until the reign of Henry VIII. the crime of murder was within the benefit of clergy.

Crimes.

Crimes may be divided generally into offences against the law of nature, *mala in se;* and offences against the laws of the community, *mala prohibita.* The former are clearly pointed out, and pretty universally acknowledged, by every people who have made any advances towards civilization; the latter are created by positive enactment, and depend, in a considerable degree, upon the particular genius, habits, and customs, of each country. Montesquieu divides crimes into four species. The first comprehends offences against religion; the second, offences against morals; the third includes offences against the public tranquillity; and the fourth, offences against the public safety. In the modern French criminal code, offences are classed according to their degrees of enormity. Offences of the first, or lowest class, are called *contraventions;* those of the second *delits;* and those of the highest class are denominated *crimes.* Each of those classes of offences is tried before a particular order of tribunals, and has a particular species of punishments annexed to it. With reference to the penal laws of England and Scotland, crimes may be divided into offences against God and religion, (atheism, heresy, witchcraft, &c.); offences against the government and state, (treason, sedition, &c.); offences against the public peace; offences against public trade; against the public police; against the persons of individuals; against private property. We shall afterwards, however, have occasion to shew, that these different species of crimes are not always very strictly defined; nor the punishments attached to them appropriated with sound legislative discrimination.

It is essential to the nature of a crime, that there be an intention on the part of the actor to commit it; for an involuntary act can neither lay claim to merit, nor induce guilt. Hence, if a person commit an unlawful act by chance, through ignorance or mistake, or by compulsion and unavoidable necessity, it is no crime, because there is no malicious intention. Hence, too, infants and idiots, or lunatics, are considered incapable of committing crimes; because, from the defect of understanding, they are held to be *incapaces doli.* By the civil law, minors under the age of ten and an half were not punishable for any crime; from ten and an half to fourteen they were punishable, if found to be *doli capaces,* capable of mischief; but with many mitigations, and not with the utmost rigour of the law.

From the age of fourteen, minors were liable to be punished even capitally. By the new criminal code of France, if the accused is under the age of sixteen, the judge is to call upon the jury to determine, whether it appears, from the circumstances of the case, that the prisoner acted with discernment. In the laws of England and Scotland, the precise age at which one becomes capable of malicious intentions is not fixed by any statute, but is left to the determination of the court and the jury, in each particular case. Under seven years of age, indeed, an infant cannot be guilty of felony; but at eight he may. A child under fourteen is presumed to be *doli incapax;* yet if it appear to the court that he was *doli capax,* and could discern between good and evil, he may be convicted, and suffer death. Where the guilt of the crime committed by the pupil arises chiefly from statute, so that its criminal nature is not so obvious, he ought not to be punished *nisi malitia suppleat ætatem,* unless he appear to have a degree of sagacity and judgment above his years; but where the deformity of the criminal act is discoverable by natural light, the pupil, if he be *proximus pubertati,* may be more easily presumed capable of committing it. In the annals of the criminal law of England, there are instances of minors being tried, condemned, and capitally punished, at the age of eight, nine, and ten years.

With regard to idiots, or lunatics, they are not chargeable for their own criminal acts, if committed when under the influence of these incapacities. But smaller degrees of fatuity or furiosity, which only darken reason without totally obscuring it, do not afford a total defence, but may operate in mitigation of punishment. If there be any doubt whether the party be *compos* or not, this fact shall be tried by a jury; and if he be so found, a total idiocy, or absolute insanity, excuses from the guilt; but if the insanity recur at certain periods, and the crime be committed during a lucid interval of understanding, the lunatic shall be answerable, as if he had no such deficiency. According to the English law, if a man in his sound memory commits a capital offence, and becomes insane during any stage of the trial, the proceedings shall be stayed, because the prisoner is then incapable of conducting his defence. On the subject of insanity, as a matter of defence against a criminal charge, and especially of crimes committed under the influence of a particular delusion, the reader will find a most profound and ingenious argument in Lord Erskine's speech for Hadfield.

The two great objects of all criminal legislation, are, in the first place, the punishment, and, in the second place, the prevention of crimes. The enormity of crimes being estimated according to the injury done to society, an ingenious writer on criminal law has suggested the possibility of forming a scale of crimes, with a corresponding scale of proportionate punishments; beginning with those which immediately tend to the dissolution of society, and ending with such as do the smallest possible injury to individuals. This idea is, perhaps, rather too refined; yet a wise legislator will endeavour to effectuate as near an approximation as possible to the general theory, by marking the principal divisions, and adhering to the order, at least so far as not to assign the highest penalties to offences of an inferior class. Upon the due distribution of adequate punishments, indeed, must the perfection of every criminal code depend. The right of inflicting capital punishments (although drawn into doubt by some writers of ability,) appears to flow directly from the principles of natural justice, and from the right of every community to protect the lives and properties of its citizens from ruffian violence. Capital punishments, however, ought not to be unnecessarily multiplied, by extending them to these offences, which do not seem to call for the *ultimum supplicium.* To shed the blood of our fellow creature, a very learned author observes, is a matter that requires the greatest deliberation, and the fullest conviction of our own authority; for life is the immediate gift of God to man, which neither he can resign, nor can it be taken from him, unless by the command or permission of him who gave it, either expressly revealed, or collected from the laws of nature or society, by clear and indisputable demonstration. It ought to be remembered, too, that of all punishments inflicted by human laws, that of death is the one by which the ends of justice are most imperfectly attained.

The principles which ought to regulate the enactment of penal statutes do not appear to have been sufficiently attended to in the criminal jurisprudence of England; and the frequency of capital punishment inflicted upon crimes very different in their nature and degrees of atrocity, has been mentioned as a subject of serious regret by many judicious writers. It is scarcely credible that, in the eighteenth century, it should have been made a capital felony to break down the mound of a fish-pond, whereby any fish shall escape; or to cut down a cherry-tree in an orchard: (Statute 9 Geo. I. c. 22. and 31 Geo. II. c. 42.) The sanguinary act of Queen Elizabeth, which made it a capital offence for any person above the age of 14 to associate for a month with gypsies, was executed in the reign of Charles I. and Lord Hale mentions 13 persons having, in his time, suffered death upon it at one assize. The writ *de hæretico comburendo,* one of the most arbitrary and oppressive laws that ever disgraced the criminal code of any country, was put in execution upon two Anabaptists in the seventeenth of Elizabeth, and upon the Arians in the ninth of James I.; nor was it totally abolished until the 29th Car. II. c. 9. Sir John Fortescue tells us, that in his day (in the reign of Henry VI.) more persons were executed in England for robberies in one year, than in France in seven; and Holinshed states, that no less than 72,000 persons died by the hands of the executioner, during the reign of Henry VIII. being at the rate of 2000 every year. It is surely most just and expedient, and necessary to the welfare and happiness of society, that some regard should be had to the nature and magnitude of the crime, in fixing the degree of punishment to be attached to its commission. Yet, by the criminal laws of England, to steal a handkerchief or other trifle, above the value of twelvepence, from one's person privately; to steal privately in a shop, goods to the value of five shillings, or in a dwelling-house, or on board a vessel in a navigable river, property of the value of forty shillings, are capital felonies, and consequently punishable in the same degree as murder, or any of the more atrocious crimes. It is a melancholy truth, Sir William Blackstone observes in his time, that among the variety of actions which men are daily liable to commit, no less than 160 have been declared, by act of parliament, to be felonies without benefit of clergy; or, in other words, to be worthy of instant death. This is surely extending the right of inflicting capital punishments much farther than is warranted by any principle of justice or expediency. The author last quoted maintains, that it is absurd and impolitic to apply the same punishment to crimes of different malignity. A multitude of sanguinary laws (besides the doubt that may be entertained concerning the right of making them) do likewise prove a manifest defect, either in the wisdom of the legislative, or the strength of the executive power. It is a kind of quackery in government, and argues a want of solid skill, to apply the same universal remedy, the *ultimum supplicium*, to every case of difficulty. It is, it must be owned, much *easier* to extirpate than to amend mankind; yet that magistrate must be esteemed both a weak and a cruel surgeon, who cuts off every limb which through ignorance or indolence he will not attempt to cure.

The disproportionate nature of the punishment attached by our penal laws to the commission of certain offences, appears to be indirectly admitted by the mode in which some of the criminal statutes are enforced. From the Tables kept by Sir Stephen Janssen, and published by Mr Howard, it appears that, in the seven years ending with 1756, there were convicted capitally in London and Middlesex, 428 persons, of whom about three-fourths, or 306, were executed; that, from 1756 to 1764, 236 were convicted, and 139, or above one half, executed; from 1764 to 1772, 457 convicted, and 233, or little more than an half, executed. During the interval between 1772 and 1802, the accounts have not been published; but from 1802 to 1808, the returns, printed by the secretary of state's office, afford very accurate information. In 1802, there were 97 convicted, and 10 executed, being nearly one-tenth; and the average yearly number of convictions for the whole seven succeeding years being about 75, the average number of executions was about 9½, or somewhat more than one-eight. From this statement it will be observed, that, at the commencement of the present reign, there were more executions than pardons of persons capitally convicted; whereas, of late, there have been about seven times as many pardoned as executed. From Janssen's Tables it likewise appears, that, in the period between 1749 and 1771, there were convicted for shop-lifting and similar offences, 240 persons, of whom 109 were executed. The convictions for the seven years ending with 1809, do not appear in the returns published by the secretary of state; but these returns show, that, during that period, 1872 persons were committed to Newgate, for privately stealing in shops and dwelling-houses, and that of these only *one* was executed.

There are some who attempt to justify this discrepancy between the letter and the execution of our criminal laws, on the ground, that, while the severe denunciations of the law itself operate as a terror to evil doers, it is expedient that the execution of it, in each instance, should be left to the discretion of the judge. The obvious answer to this proposition, however, readily occurs; namely, that such a system is directly contrary to every just principle of criminal legislation; that it tends to confound all proper distinction in crimes, and vests in the judges, without any adequate responsibility, a most awful discretionary power, in regard to the punishment of offences, which the legislature only ought to have the right of exercising. Terror itself, without regard to the dictates of justice and expediency, is ever a wretched principle of government or legislation; and in the enactment of laws, as little as possible should be left to uncertainty, or chance. Such a system, too, as that we have been contemplating, generally defeats its own ends; and it were easy to enumerate a multitude of evil consequences, which may, and actually do, result from such a method of dispensing criminal justice. The excessive severity of laws, says Montesquieu, hinders their execution: when the punishment surpasses all measure, the public will frequently, out of humanity, prefer impunity to it. The injured, through compassion, will often forbear to prosecute; juries, through compassion, will sometimes forget their oaths, and either acquit the guilty, or mitigate the nature of the offence; and judges, through compassion, will respite one half of the convicts, and recommend them to the royal mercy. In short, the very object of all laws, viz. that of having a clear, fixed, and known rule of conduct, is placed entirely out of view; the connection between the crime and the punishment, in each instance, is utterly lost; and no man is distinctly aware of the consequences that may attend his actions.

Beccaria justly observes, that crimes are more effectually prevented by the *certainty*, than by the *severity* of punishments. If it were possible, says Sir Samuel Romilly, that punishment, as the consequence of guilt, could be reduced to an absolute certainty, a very slight penalty would be sufficient to prevent almost every species of crime, except those which arise from sudden gusts of ungovernable passion. If the restoration of the property stolen, and only a few weeks, or even a few days imprisonment, were the *unavoidable* consequences of theft, no theft would ever be committed. No man would steal what he was sure that he could not keep; no man would, by a voluntary act, deprive himself of his liberty, though but for a few days. It is the desire of a supposed good which is the incentive to every crime. No crime, therefore, could exist, if it were infallibly certain, that not good, but evil must follow, as an unavoidable consequence to the person who committed it. This absolute certainty, however, is unattainable, where facts are to be ascertained by human testimony, and questions are to be decided by human judgments. All that can be done is, by a vigilant police, by rational rules of evidence, by clear laws, and by punishments proportioned to the guilt of the offender, to approach as nearly to that certainty as human imperfection will admit. By the system of enacting severe laws for the punishment of inferior offences, and leaving them to be executed, in each instance, at the discretion of the judge, these sound principles are completely violated: there is no certainty in the law; and the consequences that may ensue to the perpetrator of each criminal act resolve into a mere calculation of chances.

Let it be supposed,—and the case we are going to state is by no means a mere speculative hypothesis,—that two individuals are tried for the same offence before two different judges, who entertain different opinions, either in regard to the administration of the law, or the enormity of the crime; the one individual is acquitted, or pardoned after conviction; the other is condemned and executed. What must be the feelings of the public upon such an occasion! and what must their ideas be with respect to the nature and administration of the criminal law! Again; a person, under the present system, may be put upon his trial for a crime, and convicted upon a charge quite different from that preferred in the indictment, and enquired into by the court. The culprit is accused of having stolen to the amount of five shillings in a shop; and it is possible that nothing beyond this charge may come before the court which is to try it. But it is also very possible that other matter may arise out of the judicial investigation; and that this incidental matter may be so important in its influence upon the ultimate result of the trial, as nearly to supersede the original subject of enquiry. The prisoner may turn out to be a person of abandoned character, generally; he may prove to have been frequently tried before for a similar offence; he may have attempted to defend himself by suborning perjured evidence. These circumstances decide the sentence; and the prisoner is condemned to suffer death, not evidently because the law makes the crime charged a capital felony, but because he has been found, or supposed, to be guilty of that for which he never was tried, and which no law ever made capital,—of having a bad character, which is not punishable at all,—or of suborning perjury, which is punishable as a misdemesnor.

All these evils, and many more, must necessarily arise from a system of criminal jurisprudence, which is not regulated according to fixed and known principles; and in which the penal enactments are left to an uncertain and arbitrary execution. For these reasons, it were certainly most desirable, that the English penal statutes should be submitted to a thorough revision; that due regard should be paid to the classification of crimes, and the distribution of punishments; and that as little uncertainty as possible should be allowed in the execution of the laws. Much credit is due to the humane exertions of that distinguished lawyer, Sir Samuel Romilly, in this department of legislation; and it is to be hoped, that these exertions may be ultimately crowned with all the success which they merit. To conclude with the words of Sir William Blackstone: "In proportion to the importance of the criminal law, ought also to be the care and attention of the legislature in properly forming and enforcing it. It should be founded upon principles that are permanent, uniform, and universal; and always conformable to the dictates of truth and justice, the feelings of humanity, and the indelible rights of mankind." See Blackstone's *Comment.* b. iv. ch. 1. and 2.; Montesquieu, liv. xii.; Beccaria, *Essay on Crimes and Punishments;* Jeremy Bentham, *Traités de Legislation Civile et Penale, &c.* par Dumont; Sir Samuel Romilly, *Observations on the Criminal Law of England, as it relates to capital punishments, and on the mode in which it is administered*; *Edinburgh Review*, vol. xviii.; and M. Dumont, *Sur les peines et les recompenses.* (*z*)

CRITICISM, in its most extended sense, is the act of judging, and of expressing our judgment on the excellencies or defects of any object to which our attention is directed. In this sense, we speak of a critic in war, a critic in wine, and even of a critic in natural beauty. But as the conceptions of others, and the manner in which they are communicated, by engaging the greatest and most interesting portion of our thoughts, present the most frequent opportunities for the exercise of this faculty, the term, from its constant recurrence in a limited sense, has been employed, when no other limitation is expressed, to signify the act of pronouncing judgment in the fine arts, and particularly in the various species of literary composition. As soon as men began to impart their ideas for the purpose of instruction or amusement, criticism would also begin. The mind is naturally jealous of a teacher, in whom there must always be some pretension to superiority, and is disposed to ascertain his title to that character, by examining the value of his information. Though pleasure alone be the object of a communication, we are equally jealous of a superior in the power of pleasing; nor is there wanting in the most uneducated understanding, philosophy enough to prompt an investigation into the causes to which the success or failure of the attempt may be ascribed. Even in conversation, we are gratified to find any extraordinary claim on our attention, sifted by one who is qualified for the task, and to whom a consciousness of the qualification is generally a sufficient incitement. Identity of interest rendering us his tacit allies, we encourage him to put forth his power against the challenger for the prevention of an unmerited triumph; and as literary composition is little else than conversation on a larger scale, the process of feeling will be similar in those to whom it is addressed. Such, indeed, is human nature, as in all periods to verify the adage, *nunquam eminentia invidia caret;* or to make

—— Each little wit
Chuckle, to see the greater hit;

and therefore the more obvious the excellence of any effort, and the increase of reputation which it produced, the more certainly would some of those, who feel themselves depressed when others are exalted, dispute the superiority of its author, or seize the opportunity to claim an acknowledgment of their own, by confirming or correcting the impression which he had made. From various motives such attempts are generally favoured. Those who took delight in the original sound, welcome its repetition in the echo of the critic; and those, whose envy had exceeded their admiration, turn a ready ear to any thing by which that uneasy feeling can be alleviated. Both have the additional gratification of seeing the energies of human nature exerted; for conflicts of the understanding, like those of the body, are always interesting to spectators, who are proud of partaking the faculties of the combatants.

Criticism, therefore, naturally grew with encouragement; and after the invention of writing, which both augmented the number of authors, and offered a better opportunity of deliberately studying their merits, the number of critics was augmented in proportion. This invention, also, gave rise to a new order of critics, whose aim was more humble, though at the same time more necessary, than that of the aspiring arbiters of literary distinction. These were *verbal*, or *emendatory* critics, who laboured rather to determine exactly what an author had said, than to pronounce in what degree his sayings were to be esteemed. They confined themselves to the task of separating the spurious from the genuine ore; but to ascertain the weight and fineness of the latter, was, in the subdivision of labour, generally reserved for others. Before the discovery of printing, the errors of transcribers, and after that discovery, their repetition from the press, rendered verbal criticism a work of difficulty and importance. The requisite qualifications for its discharge were extensive learning, penetrating judgment, habitual familiarity with the turn of thought and phrase peculiar to the writer, and a nicety of idiomatic *tact*, which practice alone could confer. The exercise of these qualities, stimulated by the growing hope of approaching the object of research, could not fail to be pleasing to their possessor, if we may judge by the pleasure which we occasionally derive from their success. To see a passage of obstinate perplexity rendered intelligible, by the change of a point, or a letter, is accompanied with those emotions of surprise and satisfaction, which naturally result from the sudden recovery of what was lost, from the completion of what was defective, from the comprehension of what was obscure, and from the triumph in human ingenuity when accomplishing an arduous effect by a slight operation. Such are the emotions which, amid numerous disappointments, we have frequently experienced, from the skilful and sagacious conjectures of a Heyne, a Porson, a Toup, a Warton, or a Tyrwhit. Nearly akin to verbal is *elucidatory* criticism, which attempts to remove obscurities, by referring to some local custom or obsolete event, by quoting the phrase from some author, where the context has made it intelligible, or by employing the united force of learning and argument to establish a meaning, which others had missed. To this class of critics, as well as to the former, considerable praise is due, for the sudden light which they are sometimes able to introduce, from a remote and unexpected quarter, into the darkest passages. Both, however, are apt to become too enamoured of the arts in which they excel, and to fatigue the reader, by forgetting the precept *ne quid nimis*. The one often prolongs his experiments on words, till we nod over the crucible, where he tries to restore them from an oxydated to a metallic form; while the other displays his erudition, by accumulating explanatory quotations, till the doubtful phrase, like a sickly infant overlaid by the nurse, is lost in the crowd that is brought to its assistance. These errors are justly ridiculed by Young.

> Imperious some a classic fame demand,
> For heaping up, with a laborious hand,
> A waggon load of meanings for one word,
> While A's deposed, and B with pomp restored.
> Some for renown on scraps of learning dote,
> And think they grow immortal as they quote.
> To patchwork learned quotations are allied:
> Both strive to make our poverty our pride.

For the justice of these remarks, we may appeal to the commentators of Holland and Germany, countries peculiarly fertile in these tedious interpreters, who, however serviceable, are no more to be compared to those who investigate the genius and spirit of an author, than the workman who repairs a rotten plank, to the scientific teacher of the art of navigation. Into criticism of the first kind few have patience to enter; but all are disposed to listen to the last. All are desirous to see their judgment of a literary work confirmed by others, in whose wisdom they confide; or to be guided by the same authority where they have had no opportunity of judging for themselves, to studies which may be profitable or pleasing. From experience, however, they would soon discover that the sentence varied with the temper, the talent, and the prejudices of the judge; and it therefore became desirable to establish a system of general and immutable rules, to which both the writer and the critic might appeal. This gave rise to what may be called the Philosophy of Criticism, or the Legislation of Taste, of which Aristotle, in his Poetics, offered an early and splendid example. Applying to poetry that faculty of generalisation, which he possessed in singular perfection, and which on all subjects he delighted to exercise, he drew from the nature and objects of the art, and also from experience of its practical effects, a code of rules to serve as its future standard. Specimens in the same department of criticism were afterwards produced by Longinus, Dionysius, and Demetrius Phalareus; by Cicero, Horace, and Quintilian; and, in modern times, the general principles of criticism have become a regular branch of academical education. Critics of this speculative character maintain more dignity than those who descend into the *arena*, and grapple with individual writers; in the same manner as the didactic politician is regarded with more general respect than one who engages, as a partisan, in the official details of contemporary government. It may be doubted, however, if the former command equal interest with those who personally " mingle in the mortal fray," and who enliven their strictures with that dramatic animation in which all are formed to delight. Polemical criticism, therefore, by its exemption from the more dignified dulness of abstract maxims, is often of greater practical benefit; as precepts, casually thrown off in the ardour of dispute, and embodied in examples which force attention by their novelty, make a deeper impression on the mind, than those which are calmly pronounced *ex cathedra*, and unassociated with any personal circumstance, to assist the memory in recalling them when required. To this may, in a great degree, be ascribed the justice of the following remark by the French Academy: " Les connoissances qui sont estimées les plus belles, sont presque toutes sorties de la contention des esprits; et il est souvent arrivé que par cette heureuse violence on a tiré la verité du fond des abimes, et que l'on a forcé le temps d'en avancer la production. Il servit superflu de faire une longue deduction des innocentes et profitables querelles qu'on a vu naitre dans tout le cercle des sciences entre ces rares hommes de l'antiquité. Il suffira de dire que parmi les modernes il s'en est emu de tres favorables pour les lettres, et que la poesie servit aujourdui bien moins parfaite qu'elle n'est sans les contestations qui se sont formées sur les ouvrages des plus celebres auteurs des derniers temps."

Criticism being thus, not only a natural, but a popular exercise of the mind, authors in all ages have been sure of encountering this intellectual reaction. Aristarchus and Zoilus, among the Greeks, have, from their severity, become generic names for the whole class of literary censors. Bavius and Mævius, among the Romans, damned themselves to immortal fame, by provoking a contemptuous notice from Virgil, and a lively imprecation from Horace; and we are told by one of the first and one of the last of the Latin classics, (by Terence and by Martial,) who dwells on the *dominæ fastidia Romæ*, that neither of them escaped the reprehension of their contemporaries. After the restoration of letters, critics were not the slowest to reappear on the scene; but, for a while, their labours were circumscribed, by the expence which they incurred, from the necessity of offering them to the world in separate publications. In the 17th century, this inconvenience was removed by the lucky project of a pamphlet, which should appear at stated intervals, and which all the critics of the day should be permitted, and even invited, to fill with their lucubrations. By this contrivance, the scale of intellectual warfare was extended from unconnected single combats, to a field where a whole squadron of the critical force might array themselves against an equal number of candidates for renown. Authors, too, could thus be brough to trial, by a sort of periodical *assize*, or *gaol delivery* of literature, (if the expression be allowable) with the greatest economy and expedition; and many scraps of critical augury were secured from the fate of the Sibyl's leaves, or becoming, by their disconnection, *rapidis ludibria ventis.*

France led the way, in her *Journal de Sçavans,* which began to be published by Salle in 1665, and was followed, in 1684, by the *Nouvelles de la Republic des Lettres* of Bayle, and, in 1686, by the *Bibliotheque Universelle et Historique* of Le Clerc. Early in the 18th century, the plan was adopted by England, where the following works successively appeared. The *Memoirs of Literature,* after eight volumes had been completed, ended in 1722: The *New Memoirs of Literature* began in 1725, making 6 vols.: *The Present State of the Republic of Letters* in 1728, making 18 vols.: The *Historia Literaria* in 1730, making 4 vols.: *The History of the Works of the Learned* in 1737, making 13 vols.: The *Literary Journal* (published at Dublin) in 1744, making 5 vols. Most of the preceding works professed to give an abstract, rather than a character, of contemporary publications. But, in 1749, the *Monthly Review,* projected by Griffiths,* a bookseller, who conducted it for more than half a century, succeeded in accommodating the public taste with that form of criticism which it still prefers; and the popularity of this work led Dr Smollet, in 1755, to establish the *Critical Review,* on a plan exactly similar. These two journals continue their regular appearance at the present day, while numerous competitors have either perished in the infancy of their attempts, or faintly protract a precarious existence. Still, however, there was room for bolder adventurers in critical speculation. The old *regime* of literary censorship had, from sanguine reliance on a stability so long enjoyed, and indolent dislike to innovation or reform, become feeble and corrupt. Those in its administration employed, from cupidity, substitutes of cheap and inferior talents, who verified the remark of Rousseau, *qu'il est trop difficile de penser noblement, quand on ne pense que pour vivre;* while the professional interests of the administrators introduced a system of favouritism and secret influence, which deprived their government of all confidence and respect. Discipline being thus slackened in the republic of letters, some able and ambitious spirits thought matters ripe for the introduction of a *new order of things,* which they accomplished, in 1802, by instituting, in this metropolis, a critical journal, which soon threw all others into the shade, by its promise of superior independence of principle, and vigour of execution. On the first appearance of the *Edinburgh Review,* its authors shewed their acquaintance with the propensities of human nature, and their readiness to take advantage of its infirmities, and of the particular temper of the present age. They might almost be supposed to have borrowed a hint from the new system of war, which they had seen so successful. Though they did not decline the occasional aid of veterans, yet their "sacred cohort" was composed of youthful adventurers, whose qualifications were known to each other, but not to the public, and whose reputation and rank were yet to be acquired by that inventive enterprise from which they anticipated more splendid effects than from the caution of practised tacticians. They first created a deep impression of their power, by an exhibition of talent far beyond the standard of the old tribunals, and by assigning each article to a person who, from the peculiar direction of his studies, could not be chargeable, like the *all-work* critics, with knowing less of the subject than the author whom he undertook to correct. They next made it evident, by an early display of vituperative ingenuity, of which the consciousness generally secures the exercise, that the power they possessed would not be tamely or tremblingly exerted. Aware of the fashionable taste for raillery and ridicule, with which even the senate is so much infected, that we may say, like Juvenal, *Natio comœda est,* they shewed their purpose to indulge it, "and sharply smile prevailing folly dead:" and thus made their readers sure, that, whatever might be the substance of the repast to which they were invited, its seasoning would be of the keenest pungency. At their outset, too, they took a tone of higher authority than critics of the longest standing had dared to arrogate, and seemed to imitate the celebrated Busby, when he told his royal visitor, as an apology for remaining covered, that "in his own school no one must appear greater than he." They knew that lofty pretensions, though they may not gain all that is demanded, seldom fail, from the timidity or indolence of mankind, to obtain more than would have been granted without them; and, notwithstanding the amplitude of their means, they did not disdain the aid of something akin to what was called in Johnson his *bow-wow* manner, nor of those intimidating insinuations of their own might, and contempt for their destined object of attack, which a contemporary conqueror had found so efficient an accession to means equally ample in a different department. By this combination of ability and address, and by the diligence with which both were sustained, the new oligarchs have risen to a dominion which was never yielded to others, and continue to be regarded as the *Dii majorum gentium* of the critical theogony. Such is the popularity of their work, notwithstanding the frequent forfeiture of its original professions, that 10,000 copies are periodically circulated; the faults of its reasonings being forgot in the splendour of its illustrations, and the occasional immolation of an innocent victim pardoned for the pleasure derived from the occurrences of the chace. An attempt at partition of empire has recently been made by a London journal, (the *Quarterly Review;*) but though a respectable force has been embodied for the enterprise, the predominance still remains with our countrymen.

After this slight sketch of the past and present state of criticism, we shall subjoin a few remarks on its advantages and disadvantages. The most important of the former ought to be an improvement of authors in the matter and style of composition. If a scholar is excited to diligence and accuracy, by the certainty that his exercise will be severely scrutinized by the master; if an accountant is guarded from error, by knowing that his calculations will be checked by a board of auditors; the same effect should be produced on writers, who are aware that their work will be stopt at its outset, and examined with rigorous jealousy, before it re-

* The history of this father of the modern system of reviewing is somewhat singular. He had been bred a watchmaker, but came to London as a bookseller, and soon after began his review. Having purchased the *Memoirs of a Woman of Pleasure* from the author, who was a Mr Cleland, (son to Col. Cleland, the *Spectator's* Will Honeycomb.) Griffiths praised the work in his review, to promote the sale. For this publication he was prosecuted, but escaped conviction, by anticipating the search of the police officers, and removing all his copies of the book at a back door of his warehouse. He afterwards failed, and the review was sold to Collins, a bookseller in Salisbury. Griffiths, however, continued manager, and recovered the property in 1780. He afterwards became rich. The short characters of books in his monthly catalogue were written by Mrs Griffiths.

ceive the marketable stamp from the assay-masters of the literary corporation. The prospect of such a scrutiny should, therefore, deter the timid, and make the forward cautious, and should thus diminish the number of flimsy productions which tend to encourage sciolism, and corrupt or retard the progress of the public taste. On this subject we may borrow the elegant language of the French Academy: "Si la censure demeuroit dans ces bornes, on pourroit dire qu'elle ne seroit pas moins utile dans la republique des lettres, qu'elle le fut autrefois dans celle de Rome, et qu'elle ne feroit pas moins de bons ecrivains dans l'une, qu'elle a fait de bons citoyens dans l'autre. Car c'est une verité reconnue que la louange a moins de force pour nous faire avancer dans le chemin de la vertu, que le blame pour nous retirer de celui du vice; il y a beaucoup de personnes qui ne se laissent point emporter a l'ambition, mais il y en a peu qui ne craignent de tomber dans la honte. Ces avis, si utiles en toutes choses le sont principalement pour les productions de l'esprit, qui ne sauroit assembler sans secours tant de diverses beautés dont se forme cette beauté universelle qui doit plaire à tout le monde."

A second advantage should be, the improvement and propagation of critical acuteness in the public mind. As periodical newspapers diffuse a knowledge of political science, and a perspicuity in noticing the misconduct of our rulers, periodical reviews, which are calculated for popular instruction, by insinuating their lessons in the *concrete*, rather than in the *abstract* form, should quicken the general sensibility to literary excellence, and render us, like the Athenians, a nation of critics. A third advantage should be, the improvement of the critics themselves. It has been often observed, that to teach is the speediest way to learn. Those who employ themselves in the detection of literary faults, should acquire, by practice, a habitual delicacy in perceiving, and promptness in avoiding them; so that their own writings ought to furnish not only rules, but models of composition, and "be themselves the excellence they draw."

If these have not been the effects of criticism, it must be owing to certain imperfections in its execution, which appear so incapable of remedy, that they may be numbered among its permanent disadvantages. Critics in general have a tendency to censure, rather than to commend. They wish to exalt themselves above their author, as an apology for assuming the office of his judge. As this cannot be accomplished by the mere acknowledgment of beauties, in the production of which they had no concern, it is attempted, by an enumeration of errors, and by claiming credit for an excess of ability, proportioned to that of which the writer has been deprived, by an original exertion of their own. Critics, too, are seldom actuated by disinterested zeal for reform in literature, nor will they sacrifice an occasion of gaining fame for themselves, to the tardy recompence for which every good teacher should wait, in the gradual improvement of his disciples. Under the influence of such motives, they are too frequently seduced to employ a microscopic eye, in eliciting or exaggerating blemishes; and if they happen likewise to excel in satirical asperity, or scornful invective, they cannot deny themselves the exhibition of their specific excellence, or an intemperate and unnecessary exercise of the scourge, merely to display their dexterity in laceration. Genius, therefore, with its usual accompaniments of pride and sensibility, will often suppress its exertions from a fear of mockery or insult, which no subsequent applause can repair; while phlegmatic dulness, which does not feel, and forward vanity, which does not fear rebuke, will continue as liberal of their communications as before; and the public must console itself with the brilliant effusions of the critic, for the double injury which they create, by becoming the involuntary cause, "That Maro will not write, and Mævius will." It is obvious, too, that where general interest is thus sacrificed to the individual vanity of the critic, he will rather deprave than refine the popular taste and his own, by creating in both a preference of impertinent smartness to liberality and candour. Philosophical or didactic criticism should produce no such unfortunate results; but should be as advantageous to literature, as to the improvement and embellishment of the mind of the critic. On the one hand, every able attempt of this description advances the inductive process, and brings us a step nearer to success, in fixing a standard of taste, and in establishing practical rules for the liberal arts, by ascertaining the qualities which give pleasure to the greatest number of cultivated understandings. On the other hand, the love and the study of these arts seldom fail to give an interesting elegance and attractive amenity to the character of the student. To excite pleasing emotions in others, is the most general expression of the object, and to be natural, graceful, consistent, and correct, the most general expression of the rules, prescribed to an artist; and the pursuit of such an end, by such means, must have a powerful tendency to influence the habitual disposition, and to impart an agreeable seasoning to the sentiments and conduct of those who engage in it. It affects even the moral feelings, for he who is most enamoured of grace, propriety, and truth in imitations of nature, can scarcely be insensible to their charms in the regulation of life.

On this point we have the concurrence of Quintilian. "*Adde quod ne studio quidem operis pulcherrimi vacare mens, nisi omnibus vitiis libera, potest: primum quod in eodem pectore nullum est honestorum turpiumque consortium: et cogitare optima simul ac deterrima non magis est unius animi quam ejusdem hominis bonum esse ac malum.*" Exceptions, we know, may be stated, but not in such a proportion as to infringe the rule; and therefore it is generally found that enlightened theorists in the polite arts, become the most captivating members, the *dulcia decora* of society, while the polemical critic, though a sturdy combatant whom it may be a boast to have seen, exhibits nothing of that "soft green of the soul" on which it is pleasing to dwell. Of this we may partly be convinced, by comparing the contumelious and irascible beings which the names of a Salmasius, a Burman, or a Warburton, present to the imagination, with the mild, persuasive, and paternal monitors, whom we contemplate in a Longinus, a Quintilian, a Bossu, or a Blair. We may add, that of all the branches of a liberal education, none are so delightful, as those of which the object is our introduction to the pleasures of taste. Such studies are accompanied by no less interest and gratification in their elementary details, than in their result; and when, at an after period, we look back to our academical instructors, a double portion of grateful reverence is felt for him, who had been most successful in unveiling to us the genuine fountains of the beautiful and sublime. We regard him as one who had enlivened and multiplied our enjoyments, and who, as if by couching the intellectual eye, had awakened us to the exercise of a new sense, and to the perception of qualities in matter and mind which had hitherto been occult. To others we seem indebted

Croatia. only for an addition to our knowledge, but to him for an addition to our nature.

In general criticism, the evil to be chiefly avoided is excessive refinement, and fastidious delicacy. The mind may become so captivated with an ideal model of excellence, as to forget that perfection is unattainable in practice, and to be less delighted with a multitude of beauties, than disgusted by a few defects in a production of genius. Thus the student, as he advances in his pursuit, recedes from its object, and instead of providing for himself a store of pleasures unknown to coarser minds, he will only sharpen his sensibility to petty vexations, increase the number of his disappointments, and improve himself in that sinister ingenuity, which extracts from every object all the pain which it is capable to produce. When the whole force of the mind is expended on the cultivation of taste, to the neglect of its other faculties, this wayward squeamishness may be innocently, though injudiciously, created; but it is far oftener the effect of finical affectation, and fantastic horror at the vulgarity of being too easily pleased. In the last case, it is deserving only of contempt; in the former, it should be counteracted, by habitually conforming our expectations to the scene in which we have been destined to act, and by cultivating that benevolent temper, which is prone to encourage every attempt to please, especially by exertions of the mind, and which, with a liberal allowance for human imperfection, is more apt to be surprised that an artist has done so much, than offended that he has not done more. When from pride of understanding, we suffer our discovery of faults, either in moral or intellectual action, to beget an indiscriminate disgust with the agent, and to prohibit our enjoyment and encouragement of his more successful attempts, the acumen by which the detection is made, will be more prejudicial than advantageous to the interests of literature, and the comforts of society. (w)

CROATIA, a country of Europe, constituting formerly a part of the ancient Illyricum, but now dependent on the crown of Hungary, is bounded on the east by Sclavonia and Bosnia; on the south by Dalmatia, Morlachia, and the Adriatic; by Carniola and Stiria on the west; and is separated from Hungary on the north by the river Drave, which is very rapid and often impassable. It lies between 44° 5′ 48″. and 46° 25′ 50″ North Lat. and 32° 0′ 12″, and 35° 5′ 30″ East Long. of Ferro; and its greatest length from north to south is about 180 miles, and from east to west its greatest breadth 110, presenting a surface of above 10,700 square miles. Formerly, however, the boundaries of Croatia were more contracted. The counties of Warasdin, Kreutz, part of Agram; the military district of Warasdin, and the frontiers called *Banalgranze*, were only incorporated with it in the reigns of Ferdinand, and Leopold I.; and the maritime districts constituted, formerly, a part of Dalmatia.

Extent.

Political division.

The present political division of Croatia consists in the civil or provincial department; and the military department. In the former are comprehended the maritime districts, known under the name of *Littoral;* and the three counties of Agram, Warasdin, and Kreutz. The military department comprehends,

1. The military district of Carlstadt, which has four regiments, viz.

The district of the regiment of Licca,
. . . . of Ottochacz,
. . . . of Ogulin,
. . . . of Szluin.

2. The military boundary of the frontiers called *Banalgranze*, divided into two regiments, viz.

The district of the first regiment of the frontiers,
. . . . second do. . . . . . do.

3. The military division of Warasdin, composed also of two regiments, viz.

The district of the regiment of Kreutz,
. . . . of St George.

Mountains.

Croatia is throughout extremely mountainous, but diversified by several beautiful and fertile vallies, and some plains of considerable extent. The highest land is on the south-east; and the principal mountains extending between Carlstadt and Dalmatia, stretch towards Istria and the Adriatic. The Wellebit range is very steep, and full of frightful precipices; and equals in elevation the highest Alps, being 900 toises above the level of the sea. Its direction is chiefly along the coast of the Adriatic, and its whole extent is 80 miles. The Kapella mountains take their rise near the lake of Plitvicza, and running towards the south, almost parallel with those of Wellebet, extend nearly 90 miles. They are divided into the little and the great Kapella, the highest of which is not above 500 toises. The mountains of Plissivicza are the loftiest in Croatia. Their rugged summits are formed of perpendicular rocks, and are 925 toises above the level of the Adriatic. These mountainous ridges, which occupy almost the whole military district of Carlstadt, present on all sides a singularly rugged and frightful appearance, and form a part of the *Mons Ardius* of Strabo, to which some German authors have improperly given the name of the Dinovian Alps. Besides these, are several smaller chains; as the mountains of Merzlavodicz, which extend from 60 to 70 miles between the sea and the rivers Kulpa and Korana; the mountains of Sichelbourg, which reach from the Kulpa along the confines of Carniola as far as the Save; the mountains of Verbacs Ka-Staza; and the Kamenita Goricza. There are also several detached mountains, the most considerable of which are, the Zyr, the Bilay, the Osstra, the Debelo-Berdo, and the Bogdanich.

On the summits of the Croatian mountains are several remarkable valleys, which are so completely shut in by lofty ridges, that the rivers find no outlet but by penetrating the soil, or by forming a subterraneous passage; and when these rivers are swollen by the rains, and finding no sufficient means of escape, they inundate the whole valley, and form a temporary lake. Of these vallies the most extensive is that of Licca, which is contained by the Wellebit mountains and those of Verbacs Ka-Staza. It is sandy and barren, and a great part of it is rendered uninhabitable by the impetuosity of the winds, which rush through the passage between the mountains. The other most considerable vallies of this description are those of Korbavia, Korenicze, and Szenski-Put. Among the mountains in the northern parts are several beautiful spots, which, by their exuberant fertility, form a striking crontrast with the bleak and barren regions which surround them. Of these the principal are, the valley of Draga, between Piket and Buccuri; that of Scarigna not far from Fiume; and that of Vinodol near Ezirquenicza, so called from the number of vineyards, with which it is covered. A considerable extent of level country reaches along the shores of the Drave to the borders of Sclavonia; and between Agram and Petrinia is a large plain above fifteen miles in length, of

Croatia. which the plain of Turoposia, so famous for its privileges, forms a part.

Rivers. The principal rivers of Croatia are the Save and the Drave, the former of which has its source in the Alps of Carniola, and the other in the Tyrol; and are both navigable. The rest take their rise in the country, and empty their waters into these rivers, or lose themselves in the cavities of the mountains: except the Zermania and the Reka, which, after a short course, fall into the Adriatic. Of these the Unna and the Culpa only are navigable. The Unna rises at the foot of mount Chemernicza near Szuha, and has such an abundant supply of water, that it is navigable almost the whole length of its course. The Culpa springs from mount Szegina, and crossing Croatia from east to west, passes into the Save near Sziszeg. Such as have their springs in the mountainous regions, present at once deep and rapid torrents, which rush with impetuosity through the narrow clefts of the rocks; and some of them form magnificent cascades, particularly the Sluinchieza, which has 43 beautiful falls, setting in motion an equal number of mills. Many of these rivers, when swelled by the rains, or by the melting of the snow, overflow their banks, and spread their waters over the country. The valleys are then converted into lakes; and, the subterraneous canals being frequently choked up with mud, it is often long before the waters can force a new passage for their escape. Considerable damage is annually sustained by these inundations, particularly in the military district of Carlstadt, the country of Dubitza, and in the neighbourhood of the

Marshes. Drave; and to them must be attributed the formation of the immense marshes which are to be found in many parts of the country. The marsh near the village of Ternowacz extends over 861 acres; and that of Chemernicza, in the district of the regiment of Kreutz, covers about 10,000. There was formerly another in the same district of 8000 acres in extent, which has been completely drained by the exertions of the Archbishop of

Lakes. Agram. Of the lakes in Croatia, those of Plitzvicza, on the heights of the Little Kapella, are most deserving of notice. They are eight in number, and communicate with one another by immense cascades, which has a very beautiful and striking appearance. Two of them are surrounded by steep and rugged rocks, which render them completely inaccessible; and they can only be viewed from the top of the precipice, from which it is fearful to look so low. Notwithstanding, however, this profusion of water, and the frequent inundations to which this country is subject, it is very remarkable that the inhabitants are sometimes exposed to all the inconveniencies of severe drought. During a dry season the springs are exhausted; the beds of the torrents are empty; and water for the common purposes of life is often brought from a distance of nearly four or five leagues.

Mines. Croatia contains several valuable mines of iron, copper, and lead; but most of them are entirely neglected, and none of them are wrought with any degree of spirit; though there are immense forests in their neighbourhood and of no other use, the only mines, at present wrought, are the copper mines of Szamabor, whose annual produce is about 2000 quintals; and the iron mines of Esuber, Brod, Mrslavodicza, and Kossna; of which that of Esuber is the most considerable, and it produces only about 1000 quintals of iron annually. It is said that there were formerly mines of silver at Streberniak and near Novi, but no attempt has been made to recover them. Some gold is gathered by the peasants in the bed of the Drave, between Mahrburg and Dernje, for which they receive from the king three florins twenty-four kreutzers for every ducat weight. The quantity produced in this way amounts annually, upon an average, to from 15,000 to 18,000 ducats. Salt, blue and green vitriol, coals, and sulphur, are also found in Croatia; and quarries of beautiful marble abound in different parts of the country. All the bridges and parapet walls on the Caroline road are built of marble, and also many of the houses in Fiume, Zeng, and Porto Re.

Mineral waters. Of the mineral waters of Croatia, the most frequented are those of Jamnicza and Laszina, the one on the left, and the other on the right bank of the Culpa; and of its hot wells, that of Tœplicza, which was known to the Romans, has the highest temperature, being 46° of Reaumur. The only salt spring at present known in this country issues from a rock near the village of Szlana; and fifteen pounds of its water contains three drams of common salt.

Climate. The climate of Croatia is very unequal, and is not to be measured by its geographical position, but depends entirely upon its relative situation with respect to the Adriatic, the Alps of Carniola, or upon the elevation of the country; while, on the coast, the thermometer of Reaumur stands at 17 degrees in other places, it will scarcely exceed 8 or 9 at most. In the military district of Carlstadt, on the mountains of Wellebit, Plissivicza and Kapella, and indeed throughout the whole western division of the country, except in the vicinity of the sea, the snow generally lies for eight or nine months; and in the narrow defiles on the heights, it sometimes continues the whole year. The most prevailing winds are the north; north-east, south, and south-west. Those which blow from the continent are dry, but those which come from the sea are almost always accompanied with rain; and it is no uncommon circumstance on the coast, to have six months of wind and rain, and a severe drought the rest of the year. The north-east wind is here most piercing and violent; and during winter often rises into furious storms, which devastate the whole country.* The only spot in this district which is free from its ravages is the narrow plain of Zermania in the regiment of Licca, which, being sheltered by the mountains, enjoys a temperature equal to that of Italy, and produces all the fruits peculiar to that climate.

Soil. Though Croatia presents several beautiful and well cultivated valleys, yet it may, in general, be considered as a barren and ungrateful country. The soil partakes much of the diversity of the climate. In the mountainous regions, except in a very few spots, it is stony and perfectly sterile; and towards the sea, one sees nothing but naked rocks, despoiled of every particle of vegetable earth by the impetuosity of the winds. The lands, however, which are situated in the north and east, and are watered by the Drave, the Save, the Culpa, and the Unna, are more fertile. They are enriched by the mud which is deposited during the inundation of these rivers;

* "Il est difficile," says Hacquet, "sans l'avoir connu par sa propre experience de se figurer combien ces vents terribles du nord-est sont dangereux, particulierement sur les côtes; tantôt ils precipitent irresitiblement dans les flots de la mer les hommes, et les quadrupedes, tantot ils les jettent contre des rochers. Beaucoup de personnes perissent aussi par une grêle de gros cailloux, que l'impétuosité de l'air souleve comme des morceaux de paille. Ce vent, qu'on appelle *la bora*, est accompagné d'un froid si penetrant, qu'il devient mortel aux personnes qui en sont atteintes en pleine campagne."

Croatia.

Soil and agriculture.

and are productive in maize, rye, oats, and other kinds of grain. There are also plenty of fruit trees, particularly plums, a few vineyards, and immense forests of lofty oaks. But agriculture is here little understood, and meets with many obstructions, as well from the indolence of the peasant, and the nature of the government, as from the sterility of the soil. In the military districts, the houses, which were formerly scattered over the country, are now collected into villages, which has removed the labourers to such a distance from their lands; sometimes three or four leagues, that they take little interest in their improvement; and consequently the only appearance of regular cultivation is confined to the vicinity of the villages. The common practice of cultivation in this country is to crop for three years, and then to allow the land to lie fallow for a certain time, according to the quality of the soil. In the military district of Carlstadt, after dunging the land, they sow it the first year with maize, wheat, or barley; the second with rye, and the third with millet or oats. They then dung it anew, or turn it for several years into pasture. Many of the peasants never think of weeding their fields; of clearing them of stones, or of draining away the stagnant water. They cultivate them as long as they will produce any thing; and then leave them to lie fallow for twelve or fourteen years until they recover their strength. The produce of wheat, rye, and barley, is estimated in common years at six for one; maize at forty; buck-wheat at six; millet at twenty; and oats at four for one. Wheat and rye, however, are only cultivated on some of the baronial lands, and in the military districts. The culture of the potatoe was introduced into this country in 1780 by the soldiers, who returned from Silesia and Bohemia after the war for the succession of Bavaria; and a considerable quantity is now produced in the county of Agram. In the county of Warasdin, however, a severe law was necessary to compel the inhabitants to the cultivation of this useful root. It was promulgated in 1802, and enjoins, that every householder shall plant a certain quantity of potatoes, under the penalty of forty strokes of the cudgel. Flax and hemp are cultivated here, but they are neither abundant nor of good quality; and cotton has been attempted in Warasdin, but with very little success. Fruits are also scarce. The most common are plums, from which the Croats distil a favourite beverage called *schliwowitza*. They rear also a few cherries, apples, and pears; and near Fiume and Buccari, olives, and figs. The best fruit is produced in the valley of Dragan; but it is most abundant in the county of Kreutz, where every peasant is obliged to engraft at least twenty-five trees every year, under pain of as many strokes of the cudgel. Vines are rather plentiful in the northern and eastern districts, and afford wine of great strength and excellent flavour. The wine of Moszvina is equal to the best Burgundy; and that of Vinodol sparkles like Champagne. It is all, however, consumed in the country, and, like the Italian wines, will not keep. Mulberries are also cultivated in considerable abundance in some districts; but pulse and kitchen stuffs are almost completely neglected; and nothing is seen in their gardens but onions, garlick, and cabbage, of which they make chou-croute, a favourite dish in Croatia.

A great part of this country is covered with immense forests. The beech is the most prevailing wood on the mountains, and the oak in the plains; but there are also elms, ashes, birches, lindens, alders, poplars, pines, and firs, which might furnish an almost inexhaustible supply for ship-building. Little advantage, however, can be derived from them, on account of their distance from sea-ports, and the difficulties of conveyance.

Croatia.

Agriculture and produce.

The meadows and pasture grounds of Croatia are very inferior to those of Hungary or Carniola; but this is owing much to the indolence of the inhabitants, and the little care that is taken to improve them. Some of them are covered with furze and briars; and the grass, after it is mown, is in general so completely neglected, that one half of it is lost, and consequently, even in the most fertile districts, there is always a great scarcity of fodder. From this circumstance, the cattle of Croatia, though they constitute the chief riches of the inhabitants, particularly in the military districts, are worse fed, and worse managed, than in almost any other country. The horses are small and weak, totally unfit for hard labour. The oxen are also feeble and exhausted, for want of proper nourishment; and it often requires six pair of them to draw a plough. The cows are equally bad, and seldom give more than two pints of milk a day during summer, and three-quarters of a pint in spring or autumn. There are a few sheep and goats, and a considerable number of swine, which feed and fatten upon the acorns in the woods. The only poultry that is reared by the peasants are turkies, of which there are prodigious quantities. Woodcocks are found here in great plenty; and stags, roe-bucks, and hares, are very numerous in the forests. The rivers abound with all kinds of fish; and the inhabitants of the maritime districts derive their principal subsistence from the tunny fishing, which is carried on with great success on the coasts of the Adriatic. Bees and silk-worms are reared here with considerable care, and are, in general, very productive. In the county of Warasdin alone there are 4000 bee-hives; and, in 1801, the military districts of Banalgranze and Warasdin exported 971 quintals of honey and wax. The same districts, in 1804, produced $35,958\frac{3}{4}$ lb. of silk pods, which was an increase of $4,413\frac{1}{4}$ lb. above the average of former years. The reader may form a tolerably correct idea of the agriculture and produce of this country, from the following statement of the productive lands, &c. in the military department for 1802:

Productive lands	2,216,838	acres.
Of which are,		
Arable	692,477	do.
Meadows and pasture grounds	522,500	do.
Vineyards	14,887	do.
Orchards and gardens	13,947	do.
Forests	973,027	do.
Produce.		
Grain of different kinds	712,453	bushels.
Flax and hemp	48,983	quintals.
Hay	1,331,073	do.
Wine	150,721	*seaux.*
Schliwowitza	14,000	do.
Cattle.

Oxen	59,196	
Cows	54,711	
Calves	48,374	
Sheep	219,535	
Goats	46,589	
Swine	98,756	

The present inhabitants of Croatia are the Croats, who

Croatia.

Inhabitants.

are in general Catholics, and are supposed to have established themselves in this country in the beginning of the 7th century. There are also a considerable number of Illyrians from the Turkish provinces, who are of the Greek church, besides Bohemians, Carniolians, Germans, Italians, and a few Jews. The Croatian mountaineer differs considerably both in disposition and in manners from the inhabitants of the surrounding states. He retains many of the customs of his remote ancestors, and particularly that spirit of independence by which they were characterised. From his infancy he is inured to hardship. He is perhaps brought into the world in the open fields, or on the side of a mountain, (if his mother has been overtaken in labour, when engaged in her ordinary occupation, as often happens from the hard work to which the women of this country are exposed,) and being wrapped in a piece of coarse cloth, or swaddled only in grass, he is immediately carried to church to be baptized. His habitation scarcely shelters him from the inclemencies of a rigorous and inconstant climate. He often feeds upon the coarsest fare; and from the frequent scarcities which prevail, and the summer droughts, he is no stranger to hunger and thirst. In the military districts he is trained to the firelock from his earliest years; and soon acquires a martial appearance, and a vigorous constitution.

The inhabitants of Licca are particularly tall and well made, of a brown complexion, a masculine air, and fierce aspect; and their voice is rough and loud. They are brave, and excessively fond of military glory; and the women will even equal in the field the feats of their husbands. They call themselves Junack (heroes,) a title which they pretend was bestowed upon them by strangers. But the most courageous of all are the Bunjifzi, who make most excellent soldiers, and generally compose the chosen militia of the country. They are devoid of all fear; and the common amusement of the young Bunjifzi is to clamber up the highest rocks on the shore, and to precipitate themselves from thence into the sea. The Croatians of the plains, however, are in many respects very inferior. They possess neither the courage, the independent demeanour, nor the bodily strength and activity of their brethren on the hills. They are enervated by premature marriages, which they generally enter into before they are fifteen years of age, their principal anxiety being to increase the number of females, upon whom devolve not only the whole management of the family, but often also the most laborious duties of agriculture; and their constitutions are farther enfeebled by the diseases incident to a sultry and humid climate. The common cure among them is cupping and bleeding, while the universal remedy among the inhabitants of the mountains is a glass of brandy mixed with pepper, or a composition of wine, vinegar, and garlic. In fevers, they use a decoction of black hellebore often with great success; but should the malady resist this remedy, they return again to brandy, mixing it with great quantities of pepper and ginger.

Houses.

The houses of the Croatian peasantry are of wood, and generally of their own construction. They consist of two apartments, one for the family and their provisions, and the other for their cattle; and the best of them are but miserable hovels, without either windows or chimneys. The hard earth is their only bed, except that of the head of the family, or of the more wealthy peasants, which is composed of a few planks raised a little from the ground, and covered with straw and sheepskins. Their furniture consists of a low table, a large trunk for keeping their money and other effects, a kettle, one or two earthen pots, a few porringers and wooden spoons, and one or two hatchets. Each carries a knife for himself, which he uses at meals, and for making several little household utensils, which is generally their employment at leisure hours. In one of these huts, sometimes 50 or 60 persons, of four generations, live together in the greatest harmony. The oldest, who is called *Gospodar*, is absolute chief of the family, and directs all the out-work; while his wife, or the oldest female, who is called Gospodina, is entrusted with the care and education of the children, and the management of the house. All their clothes are made by the women, who both spin the flax or wool, and weave it into cloth. The common dress is a shirt with large sleeves, having the neck, which is always open, and the wrists embroidered with blue woollen thread; a vest, after the Hungarian fashion, with a double row of buttons; white pantaloons; short woollen stockings; and sometimes Hungarian boots. In a red belt the Croatian carries his pistols, and a long knife called hanshar, and over all he throws a red cloak. The richer inhabitants wear a long pelisse of green or blue cloth, which they use chiefly for show, and which they seldom lay aside even in the hottest weather. Their principal ornaments consist of ten or twelve silver rings fastened to the left side of the vest, which make a gingling noise when they walk. This is always considered as a sign of gentility, as are also large silver buttons on the pelisse. The Illyrians wear in general a red bonnet, and the Croats a hat or a fur cap. The shirt of the women descends to the feet, and its sleeves, which are of finer cloth and embroidered, are tied with silk ribbons; a woollen robe of the same length is bound round the waist with a girdle, and fastened on the breast with large silver clasps, gilt and ornamented with false stones. An apron before and behind is formed of pieces of fringed carpet of different colours; and their stockings are of blue cloth intermixed with small pieces of red and green. During summer they throw aside the woollen robe, but retain all the rest. Their hair is plaited in two tresses, which hang down upon the breast, and which have small bells, counters, and other ornaments fastened to their extremity. Among the more wealthy these are formed of gold, silver, or mother-of pearl, and are sometimes so numerous that the weight of half a pound is suspended from each tress. They wear upon the head an embroidered handkerchief after the Turkish fashion, and cover the fingers, and even the thumb, with a profusion of brass rings. Girls, however, have only one tress, which is decked with ribbons, and cover the head with a small red bonnet trimmed with gold or silver lace.

Food.

The common food of the Croats consists of bread and other farinaceous preparations, milk and cheese. Those in the plains, live much upon fruit, and few of them can afford wheaten bread. They use very little butcher meat; and it is only at marriage feasts, or at the conclusion of the hay season, and harvest, that they can indulge themselves with such dainties. The prevailing dishes are pottage, the same as in Scotland, but seasoned with butter or oil, and sometimes milk; vermicelli; and chou-croute. Oat-bread is in general use, but they also bake in the cinders a kind of unleavened cake of flower, barley, and rye, which they call *pogatschen*; and during Lent they eat nothing but herbs and roots, boiled in water, with a little salt. Dalmatian wine is the favourite beverage of the inhabitants of Licca, but they have seldom an opportunity of regaling themselves with it, except on great feast days. A liquor made from pears and barberries often supplies its place, and in general they content themselves with water or milk. In the wine districts, wine is in general use, but the produce of their vineyard seldom lasts above five or six months, never almost until the new vintage.

Character.

The moral character both of the Croats and Illyrians, is a mixture of good and bad qualities, frequently found even among the most uncivilized and savage tribes. They are hospitable, frugal, patient of fatigue and hunger, and always ready to oblige and assist one another; but they are, on the other hand, revengeful, indolent, intemperate, deceitful, and addicted to robbery. On the mountains, every one who arrives during a repast, is obliged to partake; and the master of a family would consider it an indelible reproach, were the traveller, or even a beggar, allowed to depart without tasting his hospitality. When compelled to endure hardship and deprivation, the Croat submits with cheerfulness; but he is in general a stranger to every kind of industry. He passes the greatest part of the day in doing nothing, while the women are continually exposed to the most laborious drudgery. "A stranger," says M. Demian, "is surprised to meet among the mountains of Wellabit and Kapella, a woman of Licca, with a large bag upon her head, a child upon her back, and another in her arms, journeying ten or twelve leagues a-day, and at the same time singing and spinning on the distaff, while her husband walks by her side without the slightest burden, solely occupied in smoking his pipe." The Croat is honest and faithful in all his dealings with his own countrymen, but an enemy to every other nation. Towards his superior he is submissive and cringing, when he wishes to gain any thing; but when he expects nothing, he is insolent and disobedient. The severity of military discipline has rendered the Illyrian particularly cunning and suspicious; and he is more inclined to robbery and brigandage than the Croat. He is also more addicted to intemperance, and the common seasons of dissipation are a marriage, a family feast, called *Kesznoime*, the anniversary of a saint, and a funeral. A marriage feast will often last several weeks, and will sometimes swallow up half a year's income. A funeral is almost equally expensive; and the father of a family, even when his wife, his mother, or his child, is lying in the agonies of death, will be busily employed in borrowing money from his neighbours, in order to purchase Dalmatian wine for the approaching entertainment. The marriage and funeral ceremonies are the same throughout the whole country; and though the Croats and Illyrians have customs peculiar to their respective origins and religions, yet they agree in these, which, indeed, in most countries, generally fix the national character.

Manufactures.

In Croatia, the arts and manufactures are almost completely neglected, and except in the principal cities and towns, where a few of the more simple and common trades are practised, there is scarcely a professed artist or manufacturer to be found in the country. Every peasant makes his own furniture, his own clothes, and even his husbandry utensils; and throughout the whole of military Croatia, containing a population of more than 376,000, there are only 2102 handicraftsmen who live by their trade. Its principal manufactures are confined to the city of Fiume, in which are made annually about 35,000 quintals of refined sugar, and 1400 *eimers* of liqueurs, both of which are mostly consumed in the Austrian provinces; 850 quintals of tanned leather; 900 quintals of wax; 3000 quintals of cordage, manufactured of Italian hemp; 2000 measures of potash; 10,000 quintals of snuff, equal to the best of Dunkirk; besides hats, delf-ware, and some cloth. There are also a sail, anchor, and cordage manufactory at Zengg; a paper-mill near Agram; glass-houses at Szusicza, and near Warasdin; a pottery at Ivanitsh; iron-forges at Tschuber and at Merzladovicza, and a copper-forge at Szamabor; a considerable number of saw-mills, of which there are nineteen in the military district of Carlstadt; and dock-yards for building coasting-vessels at Buccari, Fiume, and Porto Ré.

Inland commerce.

From the account that has been given of the productions and manufactures of Croatia, it cannot be expected, that, after supplying its own wants, it will have any great superfluity to spare to its neighbours. With the exception of wood, cattle, and a little corn, therefore, its commerce consists chiefly in exchanging the commodities and productions of other countries. Kostainicza, a frontier town on the banks of the Unna, is the great staple of its land commerce, which indeed is but inconsiderable. It draws from Turkey raw hides, which pass into Austria, dressed sheep-skins, furs, vine-shoots, honey, lintseed, a great number of cattle and pigs, destined for Italy and the Austrian states, and some horses, amounting in all, between the years 1794 and 1803, to 649,626 florins and 15 kreutchers; while Croatia in return, gives in the same time, a small quantity of schliwowitza, hemp, mercery, steel, earthen-ware, copper utensils, linen, *opanken* or Croatian shoes, salt, sieves, soap, and tobacco, to the value of only 58,332 florins 36 kreutchers; making a balance in favour of the Turks of 591,283 florins 39 kreutchers. The oxen which come from Sclavonia, Hungary, and Bosnia, are fed on the pastures of Croatia, and are generally bought by the merchants of Carniola, and carried to Venice. The number of pigs and horned cattle exported, in 1082, from the military district of Warasdin amounted to 6,138 head, and were valued at 114,966 florins. The merchants of Ivanich carry on a considerable traffic in honey and wax, which they send to Oedenburg and Upper Austria; and Austria draws also a little corn from the counties of Warasdin and Agram.

Maritime commerce.

The maritime commerce of Croatia, however, is more important. Hungarian corn is its principal export, which is brought up the Save as far as Sissek, and then conveyed by the Culpa to Carlstadt, which is the great emporium of Hungarian produce. It is then transported by the Caroline road to Fiume, or by the Josephine road to Zengg. In 1794, there were loaded at its principal sea-ports 100,000 bushels of wheat, 200,000 bushels of oats, chiefly for Dalmatia, Genoa, Trieste, and Cadiz; and between the years 1800 and 1804, about 60,000 quintals of corn were annually transported from Carlstadt to Zengg. Another valuable article of their maritime commerce is tobacco, which is exported, partly manufactured and partly in leaves, to Genoa, Ancona, and Naples. In 1780, its exportation amounted to 24,905 quintals; but, in 1792, this quantity was diminished to 10,918 quintals. It has of late years, however, been again on the increase. Wood forms another important object of exportation; and were the means of conveyance in any degree commensurate with the immense forests which cover this country, Croatia could vie with any nation in Europe in this lucrative trade; but for want of proper roads, very little of its excellent timber

Croatia. Commerce.

can be brought to the market. Such, indeed, only as grows in the vicinity of the coast is of any use in this respect; and the city of Fiume is even obliged to draw its cargoes from the forests of Cluna in Carniola. Markets for cattle are held several times a year near Fiume, where large herds are brought down from the interior for exportation to Italy and Venice, and are generally exchanged for salt. In 1801, the military district of Carlstadt alone furnished cattle to the value of 234,383 florins 37 kreutchers. The other exports of Croatia are honey and wax, to Venice, Trieste, and Messina; glass to Italy; and also some sugar, cordage, cloth, &c.

The principal imports of Croatia, for its own consumption, consist in sea-salt, Dalmatian wine, oil, sugar, maize, and hemp. The salt is derived chiefly from the Venetian Islands, and also from Barletta and Manfredonia, in the kingdom of Naples. The consumption of this article in the military districts alone, was valued, in 1801, at 230,000 florins. The annual importation of wine from Dalmatia amounts to 700,000 florins, and of brown sugar, for the refining house at Fiume, to about 600,000 florins. A considerable quantity of maize is brought from Romania and the Venetian Islands, which is used by the inhabitants of the coast, and of the adjacent mountains of Carniola, in making their bread and *polenta*. In the eastern districts of Croatia, however, as well as in Sclavonia and Hungary, this grain is used only for feeding pigs. A more precise idea of the nature and importance of Croatian commerce will be derived from the following Tables:

Articles exported in the year 1780.		*Articles imported in the year* 1784.	
Tobacco,	24,905 quintals.	Cotton, to the amount of	35,000 florins.
Wool,	158 do.	Coffee,	67,000 do.
Cheese,	23 do.	Hides,	22,000 do.
Tallow and soap,	209 do.	Hemp,	48,000 do.
Corn,	22,762 sacks.	Maize and other corn,	148,000 do.
Charcoal,	28,612 paniers.	Citrons,	6000 do.
Staves,	158,935	Linen,	19,000 do.
Potash,	1249 quintals.	Olive oil,	38,000 do.
Hides,	381 do.	Paper,	6000 do.
Honey and Wax,	598 do.	Rice,	9000 do.
Glass-ware,	267 do.	Sea salt,	54,000 do.
Refined sugar,	3883 do.	Wine from Austria,	28,000 do.
Syrup,	929 do.	Do. from foreign countries,	26,000 do.
Dried and salted fish,	330 do.	Brown sugar,	369,000 do.
Salted meat,	413 do.		
Cordage,	218 do.		
Prunes,	97 do.		

Value of articles imported and exported during the years 1793 *and* 1794, *at the sea-ports of Fiume, Buccari, Porto-Ré, Czirkvenicze, Szeloze, and Novi.*

The number of vessels which arrived at the above ports, in 1794, was 2375, and 2353 departed.

The commerce of this country suffers greatly from the want of proper means of conveyance. None of its navigable rivers run towards the Adriatic, but, taking an easterly direction, fall into the Danube, whose lengthened course, after it receives their waters, before it reaches the ocean, renders them of very little service in expediting the conveyance of its produce towards the coast. These rivers are also of very difficult navigation. Immense trees half sunk in their bed, requires the greatest address on the part of the sailors to avoid; and indeed, the circumstance of these rivers being so frequently liable to change their course, precludes all expectation that these defects will ever be completely remedied. Attempts were made some years ago to facilitate the navigation of the Save; but it has as yet come to nothing, though the estates of Carniola voted 12,000 florins for the purpose. It was also in contemplation, in 1771, to render the Culpa navigable from Carlstadt to Brod, which would have been of vast importance to the commerce of Hungary. The project was renewed in 1800 by a society, at the head of which was the Bishop of Agram; but no decided measures have yet been taken for its ac-

Croatia. complishment. The only method of transporting merchandize from Carlstadt to the coast is by land, which is so troublesome and expensive, that the merchants of Fiume and other sea-ports can draw their supplies at a cheaper rate from the Italian and Venetian states. The principal roads in this direction are the Caroline way and the Josephine way. The former, which reaches from Carlstadt to Fiume, and is about 85 miles in length, was formed in 1726 by Charles VI. It is cut entirely in the rock of the mountain which it traverses; but is very injudiciously planned, and almost totally unfit for waggons. Another road has been projected in the same direction, and is already finished as far as Merselwodicze. The declivities are more gentle, and it is in every way more convenient for passengers. The Josephine way lies between Carlstadt and Zengg, and passes over the Kapella. It is both shorter and less mountainous than the Caroline way; and 300 workmen are employed in keeping it in repair. The other roads are very indifferent. The route from Carlstadt to Austria passes through Carniola and Carinthia, by Motting, Laybach, and Klagenfurth; that from Agram is by Cilli in Styria, and Volkermarkt in Carinthia; and that from Warasdin is also through Styria and Carinthia, by Pettau and Mahrburg. The road to Hungary takes the direction of Kopreinitz and Dernje, and that to Sclavonia is by Ludbring. But what is still more grievous than the inconvenience of bad roads, is the dishonesty of the waggoners. It is almost impossible to trust them with any kind of merchandize, particularly corn, which they frequently sell for their own advantage, or pawn for liquor at the inns on the road.

As Croatia forms an integral part of the kingdom of Hungary, we must refer our readers to that article for information respecting its government, the administration of justice, its revenue, military force, and other public establishments; also, its coins, weights, and measures. We may here merely observe, that when Croatia attained its present extent in the reign of Leopold I. it was divided by that prince into counties, to which he nominated governors, called *Obergespanne*, who, however, did not then enter upon their office, as the counties were immediately submitted to other administrators, named *Ban*, a word signifying lord in the Croatian language. They were, however, effectually installed into their office in the reign of Maria Theresa, and made responsible to a council, whose president was the *ban* of Croatia.

Religion. The inhabitants of Croatia profess, in general, the Roman Catholic religion, though in the military department there is a great proportion of Greek schismatics. The Roman Catholics are under the jurisdiction of the diocesan bishops of Agram and Zengg, the former of whom is the richest dignitary of the kingdom. He possesses immense domains in Croatia and the Bannat, which yield him an annual revenue of 111,000 florins; and also other considerable privileges, among which is the sovereignty over 105 vassal barons, who hold their fiefs immediately from him, and pay an annual acknowledgment of two or three ducats. His metropolitan chapter is the most numerous in the Hungarian states, and consists of a provost, and twenty-seven canons. The bishop of Zengg has a revenue of 12,000 florins a year, and his chapter consists of a provost and five canons. The number of Roman Catholic parishes in Croatia amount to 359, of which 253 are in the diocese of Agram, and 106 in that of Zengg. There are also 16 convents. The Greek schismatic church possesses 158 parishes in Croatia, of which 149 are in the military department; and besides its parish churches, it has 77 chapels of ease. To these are attached 302 ecclesiastics, who are subject to the authority of the bishops of Carlstadt and Pakratz, and are maintained entirely at the expence of their flocks. Government contributes nothing either to the building of their churches, or the support of their pastors. Even the Catholic clergy in some of the districts depend upon the stated contributions of their parishioners, which is fixed by law;—every peasant paying so much for every acre of arable land, &c. The Croatian Catholics, though very deficienti n religious knowledge, are neither so ignorant nor superstitious as the Greek schismatics. These last make the whole of their religion to consist in the hearing of mass, and the observance of Lent, which are the continual subjects of the discourses which they hear from the pulpit; and they consider robbery or murder more venial crimes, than to eat during Lent with a spoon that has been dipped in broth. Few of them can repeat the Lord's Prayer, or know even how to make the sign of the cross. The clergy are almost equally ignorant with their parishioners, and often more immoral; and are treated with respect only when engaged in their public duties. Though the Protestant religion is tolerated by an edict of Joseph II. yet there are scarcely any of the inhabitants of that persuasion. In 1802, there were only five Protestants in the whole military department.

Education. In Croatia there are no seminaries of education of any repute; and there is not an individual in the kingdom who has made any figure either in the arts or sciences. In the civil department, there are only 35 public schools for Catholics, supported by government, besides three lyceums. Each of these lyceums has five professors, and are, in general, well attended. In 1804, there were at Agram, 309 students; at Warasdin, 280; and at Fiume, 92. There is also an academy at Agram, consisting of ten for the study of law and philosophy. In military Croatia there are fifty-three national schools, besides a lyceum at Zengg. These schools, however, were instituted by government solely for Catholics, though in this department nearly one half of the population belong to the Greek church; and there are only five schools in Croatia for the instruction of Greek schismatics.

Population. Considering the general sterility of this country, the indolence of its inhabitants, and their ignorance in almost every branch of rural economy, one would be led to expect rather a scanty population; but so far is this from being the case, that, in proportion to its extent, Croatia contains more inhabitants than any of the other Hungarian states, and surpasses in this respect even the Austrian provinces of Carniola, Carinthia, and Western Gallicia. According to Lichtenstern, the population of civil or provincial Croatia in 1787, amounted to 388,854; and by the census taken in 1802, that of the military department was 376,180. According to the latest and most authentic statistical tables, there are in

	Civil Croatia.	Military Croatia.
Cities	7	6
Market Towns	13	
Villages	2080	1240
Prædien	8	
Houses	40,046	36,307
Total number of houses		76,353
Total number of inhabitants		765,034

Crocodile. None of the villages are built with any regularity, but generally consist of a number of huts scattered up and down at a considerable distance from each other. The houses are for the most part constructed of wood except upon the coast, and in some of the principal cities and towns, where stones or brick are used, and sometimes marble. Cities. The principal cities are: *Agram* or Zagrab on the Save, the capital and a bishop's see, which is a well built and populous town, containing nearly 9000 inhabitants; *Carlstadt* on the Culpa, built in 1579, and defended by a fortress; *Warasdin*, situated in a plain on the Drave, with a castle, and 4000 inhabitants: *Fiume*, a sea-port on the Adriatic, with a citadel and a tolerable harbour; *Zengg*, a well fortified little town near the sea, containing several churches and convents, and 2744 inhabitants; and *Carlsbago*, a trading town south of Zengg, with a good harbour, and 995 inhabitants. See Demian *Tableau Geographique et Politique des Royaumes de Hongrie*, &c. (*p*)

CROCODILE. This is an amphibious animal, which may be ranked among the most hideous and disgusting of all that nature has disseminated over the earth, or in the waters. Aversion and alarm are equally excited by its appearance in those countries which it infests; and where it is only known by name, its treacherous ferocity has become proverbial.

Naturalists have scarcely established the real difference between the crocodile and the alligator: some maintain that they are identically of the same species, that the crocodile of the Nile is the alligator of St Domingo, Louisiana, or Carolina, while others conceive that there are slight distinctions between them. Cuvier enumerates twelve, however, which he concludes are different either from structure or habits; six *crocodiles* properly so called, four *alligators*, and two *gavials* or *longirostres*. Our observations shall therefore be general, and such as are applicable to those characterised as the crocodile of the Nile, the Gangetic crocodile, and the alligator.

The crocodile is a lizard of enormous size, covered with scales, which are so hard as to resist a musket-ball: its feet are provided with strong sharp claws, and an immense mouth opening as far as the ears, exhibits two rows of teeth like a saw, fitting into each other when it is closed; the eyes are large, prominent, situated on the very summit of the head, and covered by a membrane like that of some birds; the ears, or auditory orifices, situated a little above them, are also covered by membranes, having a longitudinal slit in the middle. In general the colour is yellowish, shaded with brown: dull green, with brown bands, or brown with yellow bands. One species is called the black crocodile, from its colour; but possibly that of the whole is affected by the place they inhabit; for animals dwelling in mud, acquire a dingy hue, which diminishes on changing their abode to pure water: the colour, besides, alters with age. The whole body is impregnated with a strong odour of musk, sometimes affecting the waters, where great numbers collect together, and is sensible at the distance of an hundred yards; but those which repair to the sea are divested of it.

If we except the elephant, the rhinoceros, and hippopotamus, the bulk of the crocodile perhaps exceeds that of every other terrestrial animal; no fishes frequenting fresh waters equal it, and but a few species of those belonging to the seas. The largest are not less than thirty feet in length, and one of only half that size is five feet in circumference: the body stands low on the ground, and the animal universally presents a dull and sluggish aspect. Nevertheless, its motions in pursuit of prey are not slow; and the difficulty which it finds in turning is the surest means of escape on land: its agility in water is infinitely greater.

These facts are better illustrated when the animal is roused to action. Its natural abode is in the water, for scarcely one fourth of its existence is passed on the earth; whence those narratives which affirm that it lives entire months without that element, are not easily to be credited. The muddy edges and thick reeds of slow and tranquil streams are its favourite haunts; and it sometimes descends rivers to within the flowing of the tide. On leaving them, it advances always with a slow pace, nearly in a straight line, its belly frequently dragging on the ground, and its head commonly elevated before it. However, it is seldom seen standing, and its chief enjoyment seems to be lying in a state of absolute quiescence. When in pursuit of prey, it swims gently and silently, just on a level with the water, until it approaches the place where some terrestrial animal comes to quench its thirst. Then curving its tail, it strikes the animal a violent blow, which is invariably in the direction of the water, and at the same time towards its own mouth. Should the animal surprised be of large size, such as a horse or an ox, the crocodile adopts another manœuvre, in seizing it by the nostrils, and forcibly dragging it under the water to be drowned. When a tortoise is seized, the crocodile raises its head above water, and with the inconceivable strength of its jaws, crushes the shell in pieces. Men, and particularly negroes, are said to be its favourite prey; and it is greedy after the flesh of dogs; and hence the negroes that hunt the crocodile are accustomed to beat the dogs, on purpose that their howling may attract it from its haunts. The prey being drowned, is conveyed to some subaquatic hole or receptacle, and left to putrefy before it is devoured: but the crocodile cannot feed in the water; it would then, as is usually credited, experience the same fate as its victim; therefore, except small fihes, the prey is always carried to the land: its structure also is such, that it must rise to the surface once in an hour, or hour and a half for breathing. Nothing that it once seizes can escape; it never quits its hold: even strong levers forced between the jaws for that purpose, have proved ineffectual; and, shaking its prey to pieces, it is swallowed without mastication. Much has been said of the stratagems employed by the crocodile to seize its prey; that it lies like a log on the banks of rivers, or floats inactive on the surface, and then springs forward whenever the victim comes within its reach. This may be partly true, though it appears under many exaggerations; for it is well authenticated, that it remains motionless until considerable objects are quite close, and evidently within its reach; then it leaps upon them. The agility of the crocodile is not so great, even when in pursuit of prey, that a man at tolerable speed may not escape, more especially by frequent deviation from the straight path: the blow with the tail, suddenly given, is principally to be dreaded, and the irascibility of the animal when attacked, or the female at the head of her young.

But in some countries, there are certain seasons when the crocodile may be assailed with impunity. Subject, like all other lizards, to torpidity, on the approach of cold, it passes part of the year in the most northerly latitudes, in a state of insensibility. It inhabits none excepting the warmer countries, and where winter is of the shortest duration; were its abode extended to the colder, it would so easily be overcome by its enemies, that the race would soon be extirpated. In North Carolina, which is within 37° of the equator, these animals are said to make large subaquatic burrows, entering two or three feet from the surface, and ascending steep banks considerably above it, where they pass the winter in a lethargic slumber. In Louisiana, according to M. de la Condamine, immediately on commencement of the colder season, thev retreat to the clayey bottom of marshes to become torpid, though the cold is not so intense as to deprive their limbs of flexibility. "The winter of that country not being rigorous, and frequently interrupted by warm days, these alternations occasion so many resurrections in the crocodile: on some days it is only in a slight state of insensibility: on others, the lethargy is so profound, that it may be cut in pieces without testifying the smallest sign of animation." The voice of the crocodile is a loud hollow growling of the most terrific description, which has been compared to the roaring of a bull; and it is principally exercised when the animal is enraged, or leaves its subaquatic retreats in spring: thus Dr Brickell observes, "these monsters roar and make a most hideous noise against bad weather, and before they come out of their dens in the spring. I was very much frighted by one of them in a creek near Bath Town, where these animals are very plenty, which happened after this manner: As I was walking near the creek side one evening, not long after my arrival in those parts, on a sudden this monster began to roar after such a dreadful manner, that the very earth seemed to tremble where I stood. I am not able to express the consternation I was in; for I am satisfied it gave me the greatest dread and surprise I was ever in, never having heard so terrifying a noise before. It continued thus roaring for eight or ten times like a bittern, but if possible an hundred times louder, which at first I imagined to be some diabolical spirit breaking through the bowels of the earth; for in the fright I was in I could think or imagine nothing else."

The crocodile propagates by eggs, of very small dimensions compared with its own enormous size; for they are little larger than those of a goose. Like many animals noxious to the more estimable parts of the creation, it is prolific, though the precise extent of its fecundity, except in a single species, is not ascertained. Some naturalists affirm that it lays an hundred eggs in a season, others fifty, and the Count La Cepede concludes, that the number may be about seventy-two. Recent observations, however, by an intelligent investigator of the whole history of this animal, prove that the crocodile of St Domingo lays only twenty-eight.

The males are infinitely more numerous than the females; from which and other circumstances it is inferred, that the crocodile is polygamous. Fierce combats for the possession of the females take place in the water during the breeding season, terrifying all the surrounding animals to flight; and the male, in displaying more than ordinary agility, announces his attachment by a horrible growling.

The female crocodile of St Domingo scrapes a round cavity in the earth, by means of her feet and snout, in which twenty-eight eggs are deposited, in circular arrangement, and all in such a manner as not to touch each other. They are laid in successive rows, the lower being protected from the superincumbent one by a bed of earth interposed. The nest is situated in a dry hillock, and the earth also fashioned into a conical form, so that the eggs lie at the depth of ten inches from the surface. This being done, the mother abandons them to be hatched by the sun: yet instinct prompts her frequently to revisit the spot, as the term of exclusion approaches. She then testifies uncommon agitation, roaming about the place, and uttering a peculiar growling, as if to awaken her hideous offspring to animation. The period of maturity being at length attained, the nascent crocodiles answer to her solicitude, by a kind of yelping like puppies. A hollow murmur in return denotes her satisfaction; and she hastens to scrape up the earth with such anxiety, that several of the young are always crushed under her unwieldy body. Having withdrawn them from their nest, the mother leads them straightway to the neighbouring water: but now her utmost vigilance is required for their preservation; for, unlike the instinct by which she is animated, the male, silently approaching, will frequently devour them before she is aware of her loss. He perpetually seeks their destruction; and the watch of the female over her young is protracted for three months from their origin.

An opinion is prevalent, that the crocodile continues growing during its whole existence, that it lives to a great age, and that the utmost limits of its size are scarcely known; whence, in addition to well-authenticated instances of some being twenty-five or thirty feet in length, others are reputed to attain the enormous dimensions of fifty feet. Though we are not enabled, from positive and conclusive evidence, either to corroborate or controvert these facts, the observations of the naturalist already cited, throw considerable light upon the subject. Where animals live in a state of uninterrupted warfare, we are aware that there is little probability of their either attaining their extreme dimensions, or the utmost duration of life; and with respect to the latter, we are inclined to ascribe a much longer period to those that dwell in the waters than is usually allowed. The crocodile of the Nile, banished to the most southern parts of Egypt, is permitted to live undisturbed, and there it is universally admitted to increase to the largest size, far exceeding what is seen in other countries. But inferences may perhaps be made from the progressive growth of the crocodile of St Domingo.

This species is nine inches and a half in length at the moment it leaves the egg, and at one year old is two feet long. Its length is doubled in three years more: and at eight years it is six feet seven inches: at sixteen years old, it is twelve feet and a half in length; and at twenty it is sixteen and a half. It now ceases to grow, and in two years more exhibits all the marks of old age. The males begin to breed at the age of ten, and the females when eight or nine; but the latter do not continue propagating above five years.

Were not the fecundity of the more powerful and destructive animals repressed either by the attack of open enemies, or their own liability to perish, they would speedily overrun the earth. It is thus that almost all are confined within moderate bounds; that destruction is ever commensurate with multiplication, and sometimes by its preponderance entire species become extinct. Many animals have inhabited this island, of which there have only been fossil remains for ages; and record has preserved the period when the last of a noxious race was destroyed. In certain places once infested by the crocodile, it is now totally extirpated, and in others its appearance is rare. In its earliest stage, we have seen that it is liable to perish, either from being crushed to death

Crocodile. by the female, or devoured by the male. A species of tortoise frequenting the Nile, makes incredible havoc among the young: and in Louisiana, another tortoise of monstrous size, ventures, with success, to attack those of considerable growth. The hostility of the ichneumon has been related from times of remote antiquity; and if we cannot agree that it proves destructive of the crocodile itself, we at least know that it devours the eggs. In this manner, the numbers of so formidable a creature, when less capable of defence, are diminished; but after having attained its utmost power, different means repress its voracity, and other enemies are on the watch for its destruction. Although the crocodile drags its prey under water to extinguish life, we have already remarked, that it must resort to shallows or the land to feed upon it; and in like manner, when attacked by the swordfish or shark, it is easily vanquished, for on opening its mouth in resistance, a torrent of water rushes in, and it is drowned. Of all the enemies, however, which the crocodile has to dread, the most inveterate is man. By a perpetual and sanguinary war carried on against it almost in every country, and by the various devices adopted for its capture, the race is prodigiously reduced. But it is no easy matter to overcome an animal endowed with such immoderate strength, and whose hide in general is impenetrable by a leaden musket ball. It is, however, more vulnerable in the belly, and a bullet discharged down the throat or into the eyes is fatal. Even harpoons or spears will penetrate the body, and will inflict mortal wounds when thrown from a skilful hand. The negroes of the river Senegal attack this huge animal either when asleep, or in shallows where its swimming is impeded, and by forcing an ox hide into its mouth, the water flows in, while heavy blows are given on the head to stun it, and it is drowned. In Louisiana, the natives contrive to thrust a piece of wood pointed at both ends into its throat; or when rushing upon the assailants, its wide mouth is met by a large stake, which is forcibly thrust down, and it is speedily destroyed. Long iron spikes are concealed in a bait, which penetrate both jaws as the animal bites; and many different methods are employed for the same object. Pits are dug for it in Egypt, and in St Domingo strong nets are spread, and it is either hunted on foot with muskets and pikes, or harpooned from boats. The animal floating like a log on the surface of the water, remains motionless until a boat is almost in contact with it; or when rising to breathe, the harpooner, by a dexterous blow, transfixes its body, and allows his line to run out. The wounded crocodile invariably descends, but the flowing blood marks its progress, and it is quickly followed by the boat; or roaring hideously, it dashes the water violently with its tail, alternately dives and returns until it is drowned, or dies from the weapon. Hunting the animal on shore is a more arduous undertaking; for, on seeking its usual haunts among the mud of fallen rivers, or thick and marshy places overgrown with weeds, frequently others start up after one is in view, and endanger the huntsman. Sometimes also the clayey bottom yielding to his weight, retains him until the crocodile's approach puts his life in imminent hazard. Besides lurking in the mud, in shallows, or among weeds, this creature retreats to holes in the banks of rivers; and the dislodging him from these, constitutes another kind of pursuit, infinitely more dangerous than any of the others: here it becomes ferocious, and resists its assailant, whereas in the water it flies before him. Several persons, armed with muskets and pikes, commonly join in the amusement, and the animal, when its retreat is discovered, is provoked to come forth by thrusting in poles. The huntsman then taking a steady aim, tries to strike the most vulnerable part; but in doing so, he must preserve extreme caution, and above all, keep at a certain distance, because the crocodile not only furiously issues out, but nimbly strikes an object with its tail towards its mouth, which is always widely distended, A recent instance occurred, where the destruction of a female crocodile, known to be near her nest, being projected, a single huntsman ventured on the pursuit. But he was himself surprised, by the animal suddenly darting from a thicket and seizing him by the thigh. The extreme torture he endured, rendered him incapable of defence, and the animal retreating backward through a narrow path, led him to anticipate a horrible death. Some accidental circumstance, however, induced it, contrary to the nature of the species, to quit its hold; the huntsman had sufficient presence of mind to present the butt end of his musket, and while the crocodile forcibly closed its jaws upon it, he took advantage of his remaining strength to escape, by screening himself from its sight. It was with much care and difficulty that he recovered from the injury. Crocodile.

From the uninterrupted pursuit of the crocodile, by these and many other methods, its multiplication is repressed. Whence M. de la Borde concludes, that not above five or six of a whole brood escape.

All the amphibia are tenacious of life. Dr Brickell says, " after the tail is cut off from the body of this creature, it will freely move for four or five days, as if it had been alive, and still joined with the other parts." Several leaden bullets, even when they penetrate, are sometimes insufficient to kill the crocodile, unless when they reach the brain, the spine, or some of the larger blood vessels. From the extreme hardness of the scales, iron balls are recommended as more effectual. In common also with most amphibia, it can survive a considerable time in abstinence; and on being opened, large stones are often found in its stomach. The use of these is not known; the vulgar affirm that there is one for each year of the animal's age, which is controverted by the best observations; and the most probable theory now formed is, that they assist in triturating the food, and enable the animal to suffer longer abstinence. Some naturalists have testified their surprise, that abstinence should not abate the ferocity of the crocodile. But it appears in general, that every animal, man not excepted, becomes more sanguinary, cruel, and ferocious, from the pain of hunger; and if we are to believe that hunger tames the lion, it is by superinducing a debility, which checks the power of exertion.

It has been confidently maintained, that the innate ferocity of the crocodile, which prompts it to bite even on bursting the shell, renders it untameable. We may ask, however, is any animal untameable? is it well established, that among quadrupeds, birds, and even those fishes and insects over which restraint can be obtained, there are any which may not be familiarized with mankind? On maturely considering the observations of naturalists, there is scarcely a single animal which may not be rendered docile. Those persons best acquainted with the means, have undoubtedly made the most ferocious tractable, either by terrifying them into subjection, or familiarizing them with habits opposite to those bestowed by nature. Thus the crocodile has certainly been tamed, and probably superstition, which ever subdues human reason, first taught mankind to do so, and to elevate this the most hideous of animals into a divinity. Nearly five hundred years before the Christian era, the inhabitants of Thebes esteemed the crocodiles of the lake Mœris sacred: from a number that were tamed, one in particular was selected, which was carefully fed and preserved; ornaments of gold or jewels were hung from the ears, and rings or chains, as a kind of bracelets, adorned the fore-legs. When these crocodiles died, they were embalmed, or deposited in sacred places; and we are told that cities were dedicated to them.

We cannot reject the concurring testimony of authors, that the crocodile is a ferocious animal; but its ferocity has undoubtedly been very much exaggerated, arising perhaps from greater apprehensions at its appearance, than the real danger warranted; and, indeed, the natural ugliness of the animal, added to the perpetual exposure of a formidable row of long sharp teeth, uncovered by lips, are well calculated to excite alarm. But the crocodile always flies from man. Unless when pressed by hunger, when roused by provocation, or anxious for the safety of its young, it never ventures to attack him. The hundreds floating on the surface of rivers may, in general, be approached with confidence; and even when assailed on the land, their first impulse is flight. Adanson, Sonnini, Denon, all coincide in opinion, that the crocodile is less to be dreaded than we are taught to believe. If we can credit Labat, there is a certain village, which he calls Bot, on the western coast of Africa, where crocodiles often appear, without injuring any one. Nay, he goes so far as to say, that children sport with them, or beat them away, and still they testify no resentment. Possibly it might be the docility of individual crocodiles, that led to his general conclusion; but he accounts for it by observing, " that the care with which the negroes feed these carnivorous animals, has changed, or at least mollified, the natural badness of their disposition."—Most probably, it is this abundance of food that prevents them from seeking to satisfy the rapacity implanted in every being which preserves itself by the destruction of animal life. Aristotle has long ago said, that nothing more is required to tame crocodiles than a supply of food, while abstinence renders them dangerous. M. de la Borde has seen crocodiles kept in a bason at Cayenne along with turtles, to which, being fed, they did no injury; and, in the Isle of Boutan, some of these animals, it is said, are in a certain degree domesticated from similar treatment. That superstitious veneration with which the ancient Egyptians beheld the crocodile is not altogether wanting in modern times, though " at this day it is neither pursued nor reverenced; and is left in peace to impart its musky odour to the Nile, or clear its waters of fishes." But in India many of these creatures are subsisted in tanks or pools, by the eleemosynary donations of travellers, who bestow a trifle of money, or present some provision to mendicant priests, to be converted to their use. On hearing the voice of their purveyor, the crocodiles are said to leave the waters, and each receives a small cake of meal, or other provender. Scarcely less extraordinary are the superstitions of the Catholics in the convent of Neguade, in Upper Egypt, who bathe in the Nile without the slightest apprehension, while devoutly believing, that their Mahometan neighbours would infallibly be devoured, because they have no faith in Christ.

Notwithstanding the circumstances which we have now related, there are too many fatal examples of mankind having perished by the jaws of the crocodile; and although neither its rage nor rapacity may be excited, it is an animal which no one unguarded can ever approach with confidence.

The ancient Romans, always delighting in sanguinary spectacles, exhibited combats between these animals and men; and the Emperor Heliogabalus, in imitation of his predecessors, ordered them to be brought from Africa, for the amusement of himself and the populace. Five were at one time collected in an artificial pond by M. Scaurus, in the games given during the period that he was ædile.

Various parts of the crocodile were formerly supposed to possess peculiar virtues in the cure of disease, and they have lost none of their repute in modern credulity; but it is singular that there should be a coincidence of opinion on this subject between the Egyptians and the natives of North America. Hasselquist assures us, that the former esteem the fat an effectual remedy for rheumatism; to which property the Americans add the cure of cancers or ulceration. The Arabs consider the eyes the most powerful aphrodisiac, while in North America the same quality is thought to reside in the teeth. The negroes sometimes make a species of helmet of the scaly integument of the crocodile, from its capacity of resisting a musket ball from a distance, and the blow of a hatchet. Many of them devour their eggs voraciously; and, in certain countries, their flesh is a considerable article of subsistence. Chiefly for this purpose the animal is hunted; " when their tails are cut off, they look very fair and white, seemingly like the best of veal; and some people eat thereof, and say it is most delicious meat, when they are not musky." It is this musky taste and odour which renders the flesh of the crocodile disgusting to Europeans; and unless the scales of the breast are removed before the animal dies, it becomes unpalatable even to the Indians. CROCUS, a genus of plants of the class Triandria, and order Monogynia. See BOTANY, p. 93.

CRŒSUS. See LYDIA.

CROIX, ST. See CRUZ, ST.

CROMARTY, a sea-port town on the eastern coast of Scotland, situated in the county of the same name. It was formerly a royal burgh; but the inhabitants, on account of the expence to which it subjected them, petitioned for a privation of their rights to send a representative to Parliament. The late proprietor, Mr George Ross, made great exertions to promote industry in this town, which induced government to contribute L. 7000 towards building a pier. Mr Ross erected extensive buildings for a brewery, and a hemp manufactory, which are still in a flourishing state. The manufactory sends annually to London about 10,000 pieces of bagging, which may be valued at about L. 25,000. Pickled pork, hams, and dried cod fish, form considerable articles of export. The bay of Cromarty has long been famed as one of the finest and safest harbours in Britain. It has been examined with the view to render it a naval depot; but though it is a safe retreat for ships in bad weather, it has been found unfit, from various circumstances, (particularly the distance of fresh water in sufficient quantity, and conveniently disposed for filling casks,) for being made a regular station. (S. K.)

CROMARTY, County of. This small district appears to have been erected into a shire at a very early period of our history. The office of sheriff was hereditary in the family of Urquhart of Cromarty, in which it was left at the conquest of Scotland by Edward. This shire originally extended no more than 10 miles, and its average breadth does not exceed $1\frac{3}{4}$ mile. The area, therefore, is only $17\frac{1}{2}$ square miles. George Viscount Tarbat, and afterwards Earl of Cromarty, procured an act of parliament in the year 1685, and another in the year 1698, by which all his property in Ross-shire was annexed to the county of Cromarty, which thus acquired an addition fifteen times its former extent. Many inconveniences have arisen from this annexation; but of late all acts of parliament relating to the improvement and police of Ross-shire, include the county of Cromarty, which is under the jurisdiction of the sheriff of Ross. A great part of Cromartyshire is well cultivated. In the old shire there are about 4000 acres of land in cultivation; and additions are annually made to the productive soil of the country.

The rock on which the soil of Cromarty chiefly rests, is commonly sandstone of the transition class. Compact felspar also occurs; but its connection with the sandstone has not been traced. It is said, that there are some appearances of lead ore on the estate of Brælangwell. As Cromartyshire ought properly to be considered as a part of Ross, we shall, when treating of the latter county, give a full statistical detail of both, and likewise some account of the mineralogy of this part of Scotland which has not yet been investigated. (S. K.)

CROMLECH. In various parts of the world rude and massy structures, the work of remote ages, are found; and antiquarians have been sedulously employed in endeavouring to ascertain their proper use. But as no written record of their origin is preserved, and as tradition is generally the offspring of credulity, fortified by the lapse of time, it is not an easy task to afford satisfactory explanations. The *cromlech* consists of an enormous stone, raised to some height above the earth, and resting almost invariably in an inclined position on the rudest pillars, commonly three in number.

Before speaking of the design of this ancient monument, we shall briefly describe a few of those still extant, especially in our own country, beginning with one of the most celebrated, now called Kits-Coty-House, in Kent. The stones composing it, as in the cromlech proper, are four in number; three of unequal height pitched perpendicularly in the ground, the fourth a great slab resting as an inclined plane upon them. It is of an irregular square figure, the two longest sides being above eleven feet in length, and the two shorter of about seven and a half; the whole being nearly two feet in thickness. By its inclined position, the higher part of the upper surface is more than eight feet and a half from the ground, while the opposite part is about a foot lower; and a rude cavity, or excavation, appears near the middle of the surface, capable of holding two quarts of water. Another large stone, eleven feet by seven, lies at the distance of 70 paces from the lower side on the earth. The minute particulars, which we now specify, have admitted of various conjectures, and some of them diametrically opposite, regarding the use of the cromlech. The view of this cromlech is widely commanded from the neighbouring hills. But elsewhere the situation is very different, such as one at Molfra, in Cornwall, on the summit of a round naked hill, consisting of an incumbent stone of fourteen feet three inches by nine feet eight, which rests, like the former, on three supporters, about five feet high.

An enormous cromlech, situated on a low bank of earth, apparently artificial, stands at Lanyon, in the same parish. Though nineteen feet long and forty-seven in circumference, its greatest thickness is only two feet, and its least within sixteen inches. It rests on four supporters, at such a height above the ground, "that a man can sit on horseback under it." Its general outline approaches to an ellipse, and it stands north and south, whereas the length of the former extends from east to west.

There is a cromlech in the parish of Drewsteignton, in Devonshire, of which the incumbent table-stone is fifteen feet long by ten, at the greatest length and breadth, and rests on three supporters. The highest part of the upper surface is nearly nine feet from the ground, and at a medium the whole is eight.

Similar structures are seen in Wales, both on the mainland, and in the islands. One of these, in the parish of Nevern, in the county of Pembroke, is situated amidst a great circle of stones, and consists of a stone eighteen feet long, nine broad, and three in thickness, incumbent on three others about eight feet high. In the vicinity, there is another large stone, supposed, as in the former case, to have some relation to the structure.

Rowland describes one of a singular figure in the island of Anglesea, consisting of a truncated pyramid, flat on the top, seven feet by six, and six in thickness, resting on three stones.

In Ireland there are many cromlechs, perhaps more than in most other countries, of the same kind. One at Ballymaseandlan, in the county of Lowth, consists of an incumbent stone, quite of a convex figure, 12 feet long by six in breadth, and apparently as much in thickness, supported on three pillars. Its weight is calculated at between 30 and 40 tons. Another at Castlemary, in the county of Cork, consists of an incumbent stone of greater superficial dimensions, resting on three pillars, at the height of nine feet from the ground; and near it lies a large round slab, of a similar description to those already mentioned.

At Tobins town, in the county of Carlow, there is an incumbent stone of enormous dimensions, being 23 feet long, and 18 broad at one end, on the upper surface of which is one large channel, and other smaller ones branching from it. Some persons have judged these channels natural, and others artificial; the under surface of the stone is plane and even, but the upper one is flat. This cromlech is situated in a low lying field, near a rivulet. Not far from the same spot, situated on Brown's hill, is a cromlech even of greater dimensions, supported on the east by three pillars, and forming an angle of 34° with the horizon. The height of the pillars is three feet, and the weight of the incumbent stone is estimated at above 89 tons.

On passing to the continent of Europe, different cromlechs are seen in several countries, and a structure which still exists on the coast of Syria, is supposed to be of the same description, though we cannot affirm that it is identically the same in all its parts. A natural rock nine feet high stands in the middle of an excavation of equal depth from the surface of the earth. This excavation forms three sides of a square, each of 165 feet, that to the north being open, and the whole forming a kind of court. Three stones placed on the natural rock support a fourth seventeen feet square; the top of which is about 20 feet from the ground. But those on the continent are not only very numerous in particular places, but far exceed the British and Irish cromlechs in size. Keysler describes many whose contents must be at least double or triple of those that have here come under our notice.

In considering the structures of antiquity, we find their gradual progression from the most perfect simplicity to a combination of various parts; first there is a single stone of memorial, an obelisk framed by the hands of Nature; next are two or more at intervals, and after different gradations, they appear in regular arranged circles, either for the consecration of some superstitious practice, or the commemoration of some noted event. The cromlech is a rude memorial of antiquity, but it is not the most simple; and besides those we have named single, and supported by three pillars, some appear resting upon two rows of supporters, and there are more than one cromlech in the same place. These are called double cromlechs; one of which is always of considerably smaller dimensions than the other; sometimes they are quite close together; and sometimes separated by a certain interval.

At Plas Newydd in the isle of Anglesey, there is a cromlech of this kind of large dimensions, which has originally been deposited on five supporters, though only three are standing; and close to the lower end is a smaller cromlech, in which there were originally four supporters, but one is now thrown down. Mr King has given the exact dimensions of all the stones composing this cromlech, whence we are enabled to collect, that the largest incumbent stone approaches to a triangular figure, each side being above thirteen feet; that it is five feet seven inches deep in the thickest part, and three feet in the thinnest; and that its total weight exceeds thirty tons. The incumbent stone of the smaller cromlech is quadrangular, and towards six feet square.

In various other places are double cromlechs, such as at Plasgwyn, where the interval is greater than in the former instance; and one in the shire of Merioneth, standing on a vast heap of stones, apparently collected together for this purpose. But here the larger of the two incumbent sloping slabs stretches over the edge of the other. It is supported by five flat upright stones, from five to seven feet high; and at about the distance of eight yards, is a large flat stone situated to the westward as at Kits-Coty-House. There is a great double or triple cromlech called the Hag's Bed, or the Warrior's Bed, near Castle Hyde in the county of Cork, which consists first of a huge stone, seventeen feet long by nine in breadth, and three thick, sloping to the edges, and supported by stones, of which some are six feet high; next is another lesser cromlech near it, the incumbent stone supported in the same way, its dimensions being eleven feet by seven; then is a third, the large stone of which is only seven feet square. A fourth stone, which it has been conjectured may have served as a fire hearth, lies to the westward on the ground. The double or triple cromlech is more common on the continent than here; Wormius affirms, that one is seldom to be found single in Denmark, but usually three at the same place, separated by small intervals.

There are also some cromlechs of a different structure, supposed to belong to another æra; such as a stone of a lozenge shape, resting on two pillars, on the top of a hill in the county of Down in Ireland; one 5 feet high, the other only 3. There is likewise a cromlech in the same county, supported by two rows of seven pillars.

Such are a few of the cromlechs still extant; from which it appears that there are slight varieties in the structure, but that almost all of them rest on only three supporters, and are in an inclined position. These circumstances are sufficient to prove that they are the work of man, otherwise we might be apt to consider their present site as produced by some convulsion of the earth, or that by gradual detrition, they have been allowed to remain incumbent on fragments.

It is universally maintained, that the cromlech owes its origin to a barbarous people utterly unacquainted with the arts. But difficulties of no easy solution occur respecting the modes which must have been practised to erect them; more especially when, at this day, the ablest mechanics can scarcely accomplish the conveyance of bodies extremely ponderous by land. Neither is simple conveyance the sole obstacle in the erection of a cromlech; for some stand on elevated places, and others on the summit of hills. Mr Rowland assumes, that the mode of elevating them was by forming "small aggeres or mounts of firm and solid earth upon an inclined plane, flatted and levelled at top; up the sloping sides of which they might, with great wooden levers upon fixed fulciments, and with balances at the ends of them, to receive them into proportionable weights and counterpoises, and with hands enough to guide and manage the engines; I say, they might that way, by little and little, heave and roll up those stones they intended to erect on the top of the hillock, where, laying them along, they might dig holes in that earth at the end of every stone intended for a column or supporter, the depth of which holes were to be equal to the length of the stones; and then (which was easily done) to let slip the stones into these holes straight on end; which stones, so sunk and well closed about with earth, and the tops of them appearing level to the top of the mount, on which other flat stones lay, it was only placing those incumbent flat stones upon the tops of the supporters, duly poised and fastened, and taking away the earth from between them almost to the bottom of the supporters; then there appeared what we now call our Stonehenge, Rollrick, and our cromlech, and where there are no incumbent stones, our standing columns and pillars." Nearly the same opinions have been adopted by all succeeding authors.

But an enquiry far more interesting than the mere erection of the structure itself, is the purpose for which it was designed; and on this subject the greatest diversity of sentiment prevails among the learned. The various theories, however, may chiefly be reduced to two; one contending that the cromlech is an altar for the sacrifice of human victims; the other that it is a monument marking the sepulchre of some illustrious personage; and a third, that they were designed for astronomical purposes.

The name by which these structures are presently known, afford little aid to the antiquarian. They are called the Giant's Load, the Hag's Bed, the Warrior's Bed, the Sun's Rock, King Arthur's Quoits, Kit's-Coty-House, and the like; denominations so dissimilar as not to be referable to any common or certain etymology. But we should wish to see an investigation into the real meaning of the word Cot, or Quoit, from which something might perhaps be gathered; for we have observed that this appellation is bestowed on various stones of memorial. Those, however, who maintain that the cromlech was for the immolation of mankind, find a near analogy in the Hebrew words, signifying a consecrated or devoted stone or altar.

We cannot doubt that those horrible rites, by which men invoked the favour of heaven, or divined the events of futurity, were practised here in the sacrifice of their fellow creatures: for historians bear testimony to the fact. Nay, there is a mount in Ireland, known by the name of *Killing Hill* to this day, having a structure nearly approaching to a cromlech, on the summit. In Iceland there is a stone called the Killing Stone, though we know not whether a cromlech be in the vicinity; and the remembrance of men being offered up on two pillars at Arles in France, is still preserved to posterity. But Cæsar, Tacitus, Diodorus, and Strabo, all unite in describing the immolation of human victims in these islands. The Druids were a race of priests or augurs, who bore a sovereign sway over the inhabitants; they were exclusively entrusted with the most solemn ceremonies, and could even select an individual for a victim, where those properly devoted were wanting. They are said to have passed from Britain into Gaul, where Diodorus thus speaks of their divinations. "When enquiring into any important event, a most surprising and incredible ceremony is performed by them; for having poured a libation on a human being destined for immolation, they strike him on the breast with a sword, and both from the manner of his fall, and the convulsions of his limbs, but still more from the manner of the flowing of his blood, they presage what is to happen." Tacitus, who has transmitted so much of the history of our barbarous ancestors, tells us that they were wont "to shed the blood of captives on their altars, and to consult the gods from the convulsions of men:" and Cæsar seems to insinuate that human victims were sometimes offered up in fulfilment of private vows. Long afterwards his assertions were proved in the close of the ninth century. Halfdan, a prince of Norway, was overcome by Einar, earl of Orkney, in the north of Scotland, who killed him, and cut out his lungs for a sacrifice to Odin.

Such being the case, it has been maintained by antiquarians, that no structure was equally suited for an awful and solemn purpose as the cromlech. It was formed of the rudest materials, as if in obedience to that command, which enjoins, "If thou wilt make me an altar of stone, thou shalt not build it of hewn stone; for if thou lift up thy tool upon it, thou hast polluted it." Its site was such, that a view of it might be commanded by surrounding multitudes, which was further promoted by its inclination; and this also in facilitating the flowing of the blood more readily, aided the augurs to their divinations. The cromlech, in short, was an enormous altar or scaffold whereon the chief Druid, if such was his province, could stand and perform the solemn rites of his religion before the assembled people; and the flat stone, frequently lying at a little distance, was a fire hearth, whereon could be placed a burnt offering.

The savage customs of mankind, in other parts of the world, afford too conclusive evidence, that superstition has no pity; and that it inculcates, that the blood of men will propitiate the Deity; and in accomplishing immolation, some analogies, with this apparent use of the cromlech, may be found. The sacrifice of human victims in Mexico took place on the top of lofty altars or pyramids of stone in the temples, where each priest tore out the heart as Einar did the lungs of Halfdan, and cast the body down. We believe also, that in Dahomy, the victims with whose blood the king now "waters the graves of his ancestors," are all slaughtered, and that, to the number of thousands, on scaffolds prepared for the purpose. There, as among the ancient Britons, the blood of captives is shed; and where human sacrifice is elsewhere practised, another custom, which they seem to have had of offering up criminals, or the lowest of the people, seems likewise known. Tacitus distinctly relates, that the Druids had sacred groves appropriated to their religious rites, which the Romans, in horror at their iniquity, rooted out, while they threw the celebrators into their own fires.

Wormius considers the cromlech as an altar of oblation. *Ararum structura apud nos varia est. Maxima ex parte congesto ex terra constant tumulo, in cujus summitate tria ingentia saxa, quartum illudque majus, latius ac planius sustinent fulciunt ac sustentant, ut instar mensæ tribus fulcris innixæ emineat.*

Near to Albersdorf, on the confines of Holstein, there stands a cromlech, and also one in the village of Bedel, by the river Elbe, on which it is yet customary for people to make an oblation before commencing any important undertaking.

Undoubtedly, the reasons for believing that the cromlech was an altar of sacrifice are specious; but although there are many situations where all the principles above detailed will strictly apply, there are cromlechs which, so far as probability goes, could not be adapted for that purpose. Some, in the first place, stand on the summit of lofty hills, which no multitude could surround; others are absolutely convex on the upper surface, which would effectually preclude the performance of any rites upon it. Likewise, the height of several is so far above the earth, and the highest part is so peculiarly placed, as to be extremely unfavourable for being seen from below. These circumstances have led intelligent antiquarians to conclude, that the cromlech is simply a large *kistvaen*, or rude sepulchre, composed of several stones. Human remains are frequently discovered, by digging below them, or in the vicinity; and on uncovering the place of interment, under barrows and cairns, a structure somewhat similar is occasionally discovered. The inclination also sometimes towards the east is thought "to be by way of adoration, as the person therein interred under it did when in the land of the living." But we cannot admit, that the discovery of human remains proves the cromlech to have been used as a sepulchre; for where is the spot almost throughout the world which has not been a grave? Besides, if it was an altar, these may be the remains of the victim interred beside it. More probably it is a monument of some noted event, or to the memory of one deceased. If of the latter description, it does not remount to the earliest ages, for single stones of memorial marked the site of interment. Jacob, to record the place of Rachel's sepulture, "set a pillar on her grave;" and the difficulties that must have attended the erection of such ponderous masses, could not be overcome by a people unacquainted with the mechanical arts. Many researches, however, for human remains have been ineffectually made below and in the vicinity of cromlechs, and some are in a situation which seems almost as unsuitable for covering a grave, or for being a monument, as they are for an altar of sacrifice. Were we to rest any thing on tradition, we should say that it is rather more favourable to the cromlech being a monument than an altar; and opinions are not wanting, especially that of Wormius, which seem to

Cromlech, Cromwell.

ascribe both these purposes to it. Nor is this at all improbable; for we know that, in many parts of the world, victims have been offered at the grave of one deceased, either at the moment of interment, or long subsequent to it.

We shall omit making any observations on the sentiments of those whose imagination has led them to conceive that the cromlech was erected for astronomical purposes; and who have conjectured, that one at Drewsteignton, in Devonshire, in particular, has subsisted above 2200 years. General conclusions are not to be drawn from a single example, more especially when it is altogether unsupported by the most remote semblance of evidence. Too much has possibly been said concerning the astronomical purposes of the rude monuments of antiquity extant in this country.

The erection of the cromlech, considering it as an altar of sacrifice, is, by common consent, ascribed to the Druids. But here also there is as little evidence of the fact. All that we know of the history of that singular race of priests or augurs is to be collected from meagre materials, in which no mention is made of huge altars of stone for the immolation of human victims.

On maturely weighing all that has been written on the subject of cromlechs, and taking into view their varieties in site and structure, it seems rather more probable that they have been designed as memorials of persons deceased, than for any other purpose; and that, after all remembrance of their original use was lost, or even while it was preserved, superstitious practices may have been performed upon them. See Wormius *Monumenta Danica*, p. 4. 7. 8.; Keysler *Antiquitates Septentrionales*, p. 5, 6, 7; King *Muminenta Antiqua*, v. i. p. 210; Torfæus *Historia Orcadum*, p. 19; Camden's *Britannia*, by Gough; Borlase's *Antiquities of Cornwall*, p. 223; Polwheles's *History of Cornwall*; Grose's *Antiquities of Ireland*, v. 1. introd. p. 11, 12; Rowland *Mona Antiqua*, p. 93—206; Wright's *Louthiana*, b. iii. p. 12, 13; *Archæologia*, v. 2. and 4; Maundrell's *Travels*, p. 20; Pennant's *Tour in Wales*, vol. ii.; and Smith's *Natural and Civil History of Cork*. (c)

CROMWELL, Oliver, protector of the commonwealth of England, was born in the parish of St John Huntingdon, on the 25th of April 1599. There is some obscurity, and consequent difference of opinion, respecting the condition and rank of his ancestors; but it is generally believed that his parents were in a respectable situation in life, and that he was remotely allied, on his mother's side, to the Stuart family, and descended, on the side of his father, from a sister of the favourite of the prime minister, and afterwards the victim of Henry VIII. It is certain, at least, that Oliver Cromwell, his mother, wife, and uncle, subscribed *Williams*, alias Cromwell, in the sale of the paternal estate, the former of which names they are supposed to have derived from Sir Richard Williams, Lord Cromwell's nephew, and the great-grandfather of Oliver Cromwell. This circumstance would place the paternal descent of Oliver from Thomas Cromwell beyond a doubt, were it not that he positively denied it; for when Goodman, bishop of Gloucester, who was desirous of obtaining the favour of the protector, dedicated a book to him, in which he claimed kindred to him, as being himself allied to Thomas Lord Cromwell, the protector replied, with a considerable degree of warmth, that "that Lord was not related to his family in any degree."

Of the character, disposition, talents, and behaviour of Oliver Cromwell while he was at school, there are very various and contradictory accounts. The probability is, that he was not marked, at this time, by any peculiarity to distinguish him from other boys, except by an uneasy and turbulent temper, which frequently led him into difficulties, and which kept him aloof, in a great degree, from the confidence and friendship of his school-fellows: this circumstance is well attested by authors of unsuspected veracity. He was distinguished also, according to some, in the very early periods of his life, by the same species of enthusiasm which entered so largely into his character, and contributed so materially to his success, when he engaged in public concerns. One effect and instance of this enthusiasm is very striking, and if it could be so well attested as to deserve implicit belief, it would prove that ambition as well as enthusiasm distinguished him in his youth: As he was lying, in a thoughtful and melancholy mood, on his bed, in the day time, he fancied he saw a spectre, which informed him, that he should be the greatest man in the kingdom. In the reality of this apparition, and of its prediction and promise, Cromwell persisted, notwithstanding he thus incurred the anger of his father and the chastisement of his master. It is probable that his natural temperament produced, and led him to indulge, in these fits of fancy, and that afterwards, when he perceived how greatly they might conduce to the high and difficult objects he had in contemplation and in hope, he pretended to be subject to them even after the strength of his mind and of his constitution had thrown them off.

On the 23d of April 1616, he was admitted a fellow commoner of Sidney College, Cambridge, where he paid more attention, and gave up more of his time, to football, cricket, and other manly and vigorous exercises, in which he was wonderfully skilful and expert, than to his studies. When he had been about two years at college, he was recalled home by the death of his father. At home he became excessively dissolute and licentious, which gave so much uneasiness to his mother, that she sent him to London, where he was entered at Lincoln's Inn. As he had discovered no predilection for the law, and his habits of idleness and irregularity were rather increased than diminished, by the temptations to which he was exposed in the metropolis, this scheme for reforming him seems to have been ill-advised. His licentiousness was now very gross, as well as constant. Almost the whole of his time was spent in the company of women of the most low and abandoned characters, in drunkenness and infamy. In consequence of this mode of life, the property which his father had left him, was speedily dissipated. Notwithstanding the profligacy of his character, and the desperate state of his affairs, he paid his addresses to Elizabeth, daughter of Sir James Bouchier of Essex, and by the interest of his relations Hampden, Harrington and Stewart, he obtained her in marriage, when he was scarcely twenty-one years of age.

Soon after his marriage, he returned to Huntingdon, and passed suddenly, and at once, from a dissolute and licentious, to a grave and sober life. This change, so striking, complete, and sudden, has not been satisfactorily accounted for; had it been to the extreme of enthusiastic devotion, it could not have appeared uncommon, but there is good reason for believing, that when it took place, he was not connected with the Puritans, but retained his belief in the doctrines and discipline of the church of England. Not long after his return to his native place, an estate of about £400 a year, situated in the Isle of Ely, which devolved to him by the death of his uncle, Sir Thomas Stewart, induced

Cromwell. him to settle in that part of Cambridgeshire. At this time, and in this place, he first became acquainted with the Puritans, and, in consequence of his connection with them, deserted the established church, and assumed, or experienced, that tone of feeling by which they were distinguished.

Soon after this change in his sentiments, he was elected a member of the third parliament of Charles I. which assembled on the 20th of January 1628. He was appointed one of the committee, who were empowered and instructed by the House to inquire into matters connected with religion; and distinguished himself by his zeal against Popery. On the dissolution of this Parliament, he retired into the country, where he wasted his estate by his negligence and inattention, his whole time and thoughts being occupied with the concerns of religion, and of the silenced ministers. At last his circumstances became so desperate, that he determined to leave the country, and to settle with his family in New England. This scheme he would undoubtedly have carried into effect, but in consequence of the great numbers whom the unsettled state of affairs, and the persecution of Puritanical tenets, induced to emigrate, a proclamation was issued to restrain such embarkations. His mind and feelings seem to have been very restless at this period; and having no other proper and sufficient object, on which to display and exert themselves, he set himself in opposition to the Duke of Bedford, and some other persons of high rank, who were desirous of draining the fen-country. Strong popular objections were urged against this scheme, and Cromwell joining in the opposition to it with great activity, vigilance, and zeal, his character and talents became better known in the country, and his influence and authority consequently extended and increased. His conduct on this occasion, indeed, was so conspicuous and remarkable, that Hampden afterwards expressly referred to, and cited it in Parliament, as a proof that he was a person capable of contriving and conducting great things.

But his character was established now, not only as a man of considerable vigour and activity of mind, but as one richly endowed with the gifts of praying, preaching, and expounding the scriptures; and to the fame which he had acquired on this account, he was principally indebted for his second election to parliament. He resolved to offer himself for Cambridge, but as he not only possessed no interest or friends there, but was not even known to the electors, it was necessary to have recourse to intrigue and stratagem, which were carried on with great adroitness and complete success. Before he could become a candidate, it was indispensible that he should acquire the freedom of Cambridge; and this he obtained by means of some of those to whom he had recommended himself by his spiritual gifts; they had influence with the mayor of Cambridge, and they represented Cromwell to him as a royalist and a gentleman of fortune. As soon as he had succeeded in obtaining the freedom, his election was secure, for the Puritanical party among the burgesses was by far the most powerful and numerous.

He spoke frequently in this parliament; but his speeches were distinguished more by the warmth and impetuosity with which they were delivered, than by arrangement of thought, perspicuity of language, or gracefulness of manner. It was, however, easy to perceive, in the midst of his perplexed and wandering periods, that his conception of the subject of debate was strong, steady, and original. He was at this time very inattentive to his dress. During one of the debates, Cromwell. Lord Digby observed him, and pointed him out to Hampden, "Pray," said he, "who is that man, for I see that he is on our side, by his speaking so warmly to-day?" "That sloven," replied Hampden, "whom you see before us, who has no ornament in his speech; —that sloven, I say, if we should ever come to a breach with the king; which God forbid! in such a case, I say, that sloven will be the greatest man in England." The remonstrance, which was passed in November 1641, and which may justly be regarded as the immediate cause of the civil war, was ably and warmly supported by Cromwell. By his conduct on this occasion, he so effectually recommended himself to Pym and Hampden, that he was admitted into their councils, and informed of their designs. In the beginning of 1642, the parliament resolved to raise an army; Cromwell immediately went down to Cambridge, where he raised a troop of horse, of which he was appointed commander. He was now in his 43d year, yet in the space of a few months he not only became an excellent officer, but had disciplined his troops so completely, that they were justly regarded as equal to regular and experienced soldiers.

It is foreign to the nature and design of the present article, to enter into a detail of the military exploits of Cromwell; these more properly belong to the province of history. The actions in which he principally distinguished himself, may, however, be briefly noticed. In the battle of Marston Moor, which changed the fortune of the war, the independents ascribed the victory to Cromwell's iron brigade; though Hollis and other writers accuse him of cowardice, in retiring from the field on account of a slight wound: this he probably did, but the charge cannot be rested on this circumstance. "Cæsar and Cromwell," observes Walpole, "are not answerable to a commission of oyer and terminer." In the second battle of Newberry, he made so bold a charge with his horse upon the guards, that his Majesty would have been in the greatest danger, had not the Earl of Cleveland preserved his master's liberty at the expence of his own. When the self-denying ordnance was passed, Cromwell was at first occasionally, and afterwards absolutely and perpetually, exempted, and appointed lieutenant-general of the army. In the battle of Naseby, 1646, he particularly distinguished himself. Fortune for some time favoured the cause of royalty; Skippon's division was disordered and driven behind the reserve; but the battle was restored by Fairfax, and the royalists had already began to waver, when they were attacked in flank and rear by Cromwell, and the confusion became irretrievable.

As soon as the king had delivered himself up to the Scots, the parliament resolved to disband part of their forces. If this resolution had been carried into effect, the designs and the hopes of Cromwell would have been overthrown; and yet he could not oppose it openly and directly; he therefore had recourse to those secret and cautious measures, in the planning and execution of which he so much excelled, wherein he was the sole agent, though he did not appear to act, or even to take any interest. Perhaps in no one instance did he succeed so completely in the object he had in view, as in this; for he managed so, that those troops on which the parliament might have depended, and of which he was jealous or afraid, were disbanded, while the army of Fairfax, over whom he possessed, in fact, the sole power, was permitted to continue on its full and regular establishment. Being now possessed of willing and adequate instruments for the prosecution of his ambitious purpose, he seized on the person of the king; and having got him into his power, he *played off* the king, parliament, and army, against one another. The king was completely deceived in his character and designs; the parliament, trusting rather to his professions of obedience and respect to them than to his actions, was equally deceived; and the army were ready to follow the man, who, when the parliament were obliged to erase their own declaration respecting them out of their journals, assured them that "now they might be an army as long as they lived." As soon as the parliament discovered the real character and designs of Cromwell, they endeavoured to crush him; but he had now gained such a powerful influence with the army, that they compelled it to acquiesce in all that he did; and, in December 1648, they took forcible possession of the House of Commons.

When it was first proposed to try the king, Cromwell declared, that "if any man moved this upon design, he should think him the greatest traitor in the world; but since Providence and necessity had cast them upon it, he should pray God to bless their counsels, though he was not provided on the sudden to give them counsel." Shortly afterwards, however, he pretended, that as he was praying for a blessing from God on his undertaking to restore the king to his former state and power, his tongue cleaved to the roof of his mouth, that he could not speak one word more, which he took as a return of prayer that God had rejected him from being king. Within a very few days after the king's death, Cromwell became a principal member in the council of state, in whose hands the executive power was placed. He seemed now near the grand object of his ambition, when a circumstance occurred which threatened to snatch it from him by those very means which he had employed to gain it. Part of the army which he commanded being dissatisfied, sent a remonstrance to their general; the ringleaders were seized and punished in an ignominious manner, but the mutiny and dissatisfaction spread, and Cromwell's own regiment put white cockades in their hats, and fixed on *Wales* as the place of their assembling. In this critical emergency, the promptitude, decision, and personal bravery for which he was distinguished, were absolutely necessary—nor were they wanting; with two regiments of horse he surrounded the mutineers, and calling out four men by name, he obliged them to throw dice for their lives, and the two that escaped were ordered to shoot the others.

In 1649, England being quiet, and the Scotch intimidated, though discontented, Cromwell embarked with his army for Ireland, and, in less than twelve months, the whole of that island was subdued. During his absence, the Scotch recovered their courage, invited Charles II. and prepared to invade England. To repel this invasion was the duty of Fairfax, but Fairfax had taken the covenants, and would not fight against the Scotch. Cromwell therefore was appointed general and commander-in-chief, and in conformity to one of his military maxims, that one invasion ought to be prevented by another, he marched into Scotland. Ignorant of the nature of the country, or of the face and situation of the Scotch armies, his supplies were cut off in the neighbourhood of Dunbar; his troops became sickly, and his retreat was intercepted. Had the Scotch general continued in his position on the heights, the English army must have surrendered; but his operations were controlled or impeded by a committee of church and state, who blamed him for his reluctance to extirpate the sectaries. Goaded by these reproaches, and in obedience to their peremptory orders, the commander of the Scotch army quitted the hills, saved the army of Cromwell, and ruined his own. At the moment when the Scotch were making this disastrous movement, Cromwell and his officers were engaged in a solemn fast; when he perceived it, he exclaimed, "They are coming down, the Lord hath delivered them into our hands!" In 1651, he gained the battle of Worcester, which, in his letter to the parliament, he styled the "crowning victory." From this time he assumed more loftiness of manner, and betrayed less equivocal symptoms than usual, of his designs and his hopes. Before, however, he could expect to succeed, it was necessary to subvert the parliament; and on this point, disguised under the idea and phrase of establishing the kingdom, he had frequent conferences with the most eminent and leading men in the nation, and particularly with the Lord Commissioner Whitlocke. He soon found that it was absolutely necessary to proceed with great caution and deliberation; the parliament were alarmed and put on their guard, and they framed a bill to continue their sittings till the 5th of November 1654. Cromwell being informed of this proposed measure, marched to Westminster with a party of 300 soldiers, whom he placed round the House. He himself went in, and listened to their debates for some time in silence, till the question being put for passing the bill, he rose and abused the members in the most violent and gross terms, and when some of them began to speak, he stepped into the middle of the House, and exclaimed, "Come, come, I will put an end to your prating;—you are no parliament, I say you are no parliament!" he then gave the signal, by stamping with his foot, for the soldiers to rush in, and bade one of them take away that bauble, pointing to the speaker's mace. The soldiers next cleared the House of all the members, and the doors were locked up. Having thus forcibly dissolved the parliament, he treated the council of state in the same manner.

On the 16th of December 165[illegible], he was solemnly invested with the office of Protector of the commonwealth of England, Scotland, and Ireland, in the court of chancery, in Westminster Hall; and he lost no time in directing his thoughts to the arrangement and settlement of public affairs, both foreign and domestic. Abroad he was feared, and made the rights of England respected. At home his administration of justice was pure and impartial; the courts were filled with able judges, and the practice of the law was freed from many imperfections and abuses. He declared his unalterable resolution to maintain liberty of conscience, and in his conduct he adhered to this resolution.

Notwithstanding he thus endeavoured to gain popularity and stability to his government, discontent prevailed; he found himself under great difficulties for want of money, and he was at last obliged to call a parliament. The superstitious cast of his mind displayed itself on this occasion; he fixed the third of September for the day on which the parliament was to assemble, esteeming it particularly fortunate to him, and on that day, though it happened to be a Sunday, the parliament met. It was, however, soon dissolved, for finding that they wished to take away his authority, and were not disposed to vote him any money, he sent for them into the painted chamber, and, after a long and bitter speech, dismissed them.

This violent proceeding increased the discontent and dissatisfaction of the nation, and several conspiracies against his life or authority were set on foot; but he discovered them all before they were ripe for execution. His want of money was partly, and for a time, supplied by the spoil which Blake collected during the Spanish war; but this being exhausted, he again summoned a parliament, having, as he conceived, taken such measures as would make them more obedient to his will than the last parliament had been. It is probable, however, that the members of this parliament would have been stubborn and unruly, had they all been permitted to assemble; but a guard was placed at the door of the House, who permitted none to enter till they had taken the oath prescribed by Cromwell. In this packed parliament an attempt was made to give him the title of *king*; but a petition from the army being prepared against it, Cromwell thought it prudent to refuse the honour, and to content himself with his former title of protector. In 1658 he was excessively alarmed by the publication of the celebrated tract, entitled "Killing no murder," the object of which was to prove, that one who had violated all laws, ought to derive protection from no law. This treatise was written by Colonel Titus, under the name of William Allen. Cromwell made many attempts to discover the real author, but in vain.

About this time he formed a project fer creating a House of Lords, and actually summoned his two sons, and some others, to take their seats in it; but when the parliament assembled, none of the old nobility made their appearance; the House of Commons would not act with the new nobles; and the new nobles could not act by themselves.

The strength of his body and mind now began to sink under his disappointments and apprehensions; he was haunted by continual terror; his own soldiers threw off their attachment and awe; his conscience was awakened by the death of his favourite daughter, who, in her delirium, upbraided him for his tyranny and cruelty; and even his wife united herself with the republican party. He knew not whom to believe or trust; he constantly wore concealed armour, and never went abroad, unless surrounded by guards, whom he suspected nearly as much as those against whom it was their office to have protected him; he never returned by the same road, nor slept thrice in the same apartment. It was utterly impossible that his constitution, already broken up, should long stand against this incessant and increasing agitation of mind; he was seized with a slow fever, which, changing into a tertian ague, soon threatened his life. His physicians informed him of his danger, but his courtly or fanatical chaplains assured him that their prayers would still be efficacious to restore him. When he was first taken ill he was at Hampton court; but on his illness becoming alarming, he was removed to London, when he first became lethargic, and then delirious; still, however, retaining in the short intervals of reason his original enthusiasm, vehemently declaring that his life was conceded to the faithful, to intercede with God as a mediator for the people. Immediately before his death, he was asked if he did not name Richard his eldest son for his successor, and to this question, which it is probable he did not understand, he answered in the affirmative. He died on the 3d of September 1658, being rather more than 59 years old.

The features in the character of Cromwell are strongly marked; his spirit was bold and enterprising, his personal courage undoubted; his promptitude and presence of mind never forsook him in the most sudden and unexpected emergencies. Whatever object he had in view, he pursued with unabated zeal and perseverance; he examined it thoroughly, made himself acquainted with the obstacles with which it was surrounded, and the means by which it might be attained; and with this information, he united the most consummate address, and such a profound sagacity in discerning the characters and designs of others, as enabled him to employ them in the furtherance of his own plans. But while he penetrated into the characters and designs of others, he threw an impenetrable secrecy over his own; even his natural enthusiasm, which it might have been supposed would have laid open his plans in the moments of its extravagance, was so curbed and disciplined by his hypocrisy, that it served the same purpose with him, which dissimilation and reserve are supposed exclusively to answer. But after he became possessed of the supreme power, he seldom stooped to obtain that by artifice which he could acquire by authority or fear; it was more agreeable and consonant to his disposition and temper to command than to deceive. His military reputation has been raised higher than a due estimation of his talents will warrant; his military talents were certainly not of the highest order or the rarest kind; they did not display themselves in the plan or conduct of a campaign, nor even in extensive combinations or masterly evolutions in the field, but rather in the enthusiam with which he inspired his troops, and in the discipline which enabled him to reap all the advantages, while he avoided the ill consequences of that enthusiasm. His talents as a statesman were of the same kind and degree; his government was founded on no exclusive or profound plan of policy, but arose out of circumstances, or was decided by them.

He had many children, six of whom lived to an advanced age. Richard, his eldest son, was naturally of a quiet and unambitious temper, of very moderate talents, and from the retired and indolent life which his father directed or permitted him to spend, wholly without experience or knowledge of the world. He succeeded nominally to the sovereign authority; and while he continued to govern without a parliament his power was respected, but as soon as he summoned it he was assailed by secret enemies and by open force, and in a very short time degraded by the army; he cheerfully laid aside his authority, and passed from the throne to a private station, in which he lived unnoticed and almost forgotten, till the 13th of July 1712, when he died at Cheshunt in Hertfordshire. See Harris' *Life of Cromwell*; Noble's *History of the Cromwells*; *Biographia Britannica*. (W. S.)

CRONBERG. See Elsineur.

CRONSTADT, or Kronstadt, a sea-port town of Russia in the government of Petersburgh, situated at the south-eastern extremity of the island Retusari, in the gulf of Finland, which is a long stripe of sandy ground traversed by ridges of granite. This island is about 5 miles long and $\frac{3}{4}$ths of a mile broad, and was covered with firs and pines when it was taken from the Swedes by Peter. It now grows a small number of birch trees, and affords a small quantity of pasture and vegetables.

Cronstadt is defended towards the sea by fortifications of granite projecting into the water, and towards the land by ramparts and bastions. Several of these were erected by Catharine; and Paul I. established a new bastion, called Ries-bank, to the south-east, opposite to Oranienbaum. The houses fronting the harbour are built of brick and stuccoed white, and the lofty and spacious magazines inspire a stranger with a high notion of the place; but this exaggerated opinion is soon corrected, when he observes the mean appearance of the houses, which are principally of wood, and are scattered up and down with little regularity.

The principal public buildings are the imperial hospital for sailors, the hospital for the town's people, and the barracks, the marine academy for cadets having been removed by Catharine II. The hospital, which is on a very large scale, contained 25,007 patients in 1788, of whom 20,924 were cured; and in 1789 the number was 16,809, of whom 12,974 were cured.

The numerous vessels which frequent this town are accommodated by three separate harbours. The eastern harbour contained 20 ships of the line and 9 frigates in the year 1778; the middle harbour is intended for frigates, sloops of war, and yachts belonging to government; and the western harbour, which is appropriated for merchant ships, can hold 600 vessels. Adjoining to it is Peter's canal, which was begun in 1719 by Peter the Great. In the same year he founded the dry docks for building and careening ships of war, but they were not completed until the reign of Elizabeth, and they have received considerable improvements from Catharine. At the extremity of these docks there is a vast bason of granite 568 feet long, containing water for the supply of the docks, which is pumped into them by a steam engine whose cylinder is 6 feet diameter, erected by the Carron Company of Scotland in 1772. The docks, which can hold 10 men of war, are faced with stone and paved with granite, and are 40 feet deep and 105 broad. The whole length of these works is 4221 feet. The dock-yards are supplied with oak from the province of Cara; and there is at Cronstadt a foundery for casting cannon, and a rope-work for manufacturing cables of all kinds.

Some idea of the trade of Cronstadt may be formed from the following Tables:

Table shewing the Number of Merchant Ships that have arrived annually at Cronstadt from England from 1753 to 1778.

	Ships.		Ships.		Ships.
1753, ...	149	1760, ...	137	1770, ...	306
1754, ...	236	1761, ...	130	1773, ...	319
1755, ...	169	1762, ...	153	1774, ...	318
1756, ...	186	1763, ...	149	1776, ...	320
1757, ...	129	1767, ...	200	1777, ...	366
1758, ...	161	1768, ...	277	1778, ...	252
1759, ...	206	1769, ...	322		

The following vessels arrived at Cronstadt in 1778.

	Ships.		Ships.		Ships.
English, . .	252	Dutch, . . .	147	Hamburgh, .	2
French, . . .	1	Spanish, . .	39	Stralsund, . .	1
Spanish, . . .	6	Russian, . .	26	Bremen, . . .	3
Russian, . . .	12	Lubeck, . .	38		
Portuguese, .	2	Rostock, . .	29	Total, . .	607
Swedish, . .	47	Dantzick, . .	2		

The population of Cronstadt is generally estimated at 30,000, the greater part of whom belong to the fleet and the garrison. The number of registered burghers does not exceed 300. See Tooke's *View of the Russian Empire;* Storch's *Picture of St Petersburgh;* Coxe's *Travels in Poland,* &c. vol. iii. p. 283, 307. 5th Edit.; and Catteau Calleville *Tableau de la Mere Baltique,* vol. ii. p. 309, 351. (π)

CROOKS, in Music, are appendages to the trumpet, French-horn, and trombone, consisting of short tubes of brass of different lengths, that fix on below the mouth-piece, for lengthening or shortening the tube by changing them, in order either to tune these instruments to the pitch of the organ or piano-forte, on which the conductor is to perform at the commencement of a concert or performance, or for changing the fundamental tone after such adjustment of the pitch, or the key in which the instrument is capable of performing, if it has not a sliding movement or other contrivance for obviating the necessity of this latter use of crooks. See CHROMATIC FRENCH HORN, TRUMPET, and TROMBONE. (ϱ)

CROPS. See AGRICULTURE.

CROSS. See CRUCIFIXION.

CROSS TEXTURE, in the manufacture of cloth, is a species of weaving in most cases applicable chiefly to those fabrics in which transparency is the principal quality, and hence very few kinds of it are used for any other than ornamental purposes. Its origin, as far as we know, is continental, although, like most other fabrics, the knowledge of it may very likely have originated in Asia. One particular fact relative to it may perhaps strengthen this conjecture, and that is the texture of the common Russian table rubber. Although the fabric of these rubbers is of the coarsest flaxen or hempen yarn, and they are sold at very low prices, the mode of weaving them is to this day unknown to the rest of Europe; and although machinery which would effect them might be devised by a person skilled in mechanical knowledge, and previously conversant with the other kinds of crossed texture in use, yet the apparatus which he must employ for an imitation of this coarse article, if conducted upon principles in any respect similar to those of other cross fabrics, would probably be more expensive than what we use for the richest silken nets.

In the absence of better and more authentic information upon the subject, some conjectures upon the means of effecting this manufacture in the most simple way, will form some part of the conclusion of this article. At present, the only remark which is drawn from the notice now taken of it is this, that the small progress which arts and sciences have hitherto made in Russia comparatively with the rest of Europe, and the existence of one of the most complicated and difficult processes of an ornamental manufacture in such a country, afford sufficient reasons to doubt the originality of its invention there. The contiguity of the Russian empire to those regions of Asia from whence the other branches of the manufacture found their way into Italy, seem to warrant the presumption, that while they found their way to the west, this particular one had by some accident diverged to the north, and established itself in a rude state among the Muscovites.

The generic distinction of this branch from all the others, consists in the twining or crossing of the warp, and hence it combines the strength of mechanical union with a greater degree of lightness and transparency than any other fabric of cloth. The common linau or gauze is the ground-work or basis of all the varieties, and its texture consists in twining two contiguous threads of warp alternately to the right and left during the operation of weaving. The figures, illustrative of the mechanical part of the operation of forming this texture, which, with a single exception, has never been discussed through the medium of the press, will be found in Plate CCXIX., which contains eight illustrations, two Figures being devoted to each species; the first exhibiting it in its open state, or in that which assimilates it to the common principles of texture; the second in that crossed or twined state which constitutes its generic peculiarity.

Plate. CCXIX. Figs. 1, 2.

The common linau, or gauze loom, is exhibited in profile elevation in Figs. 1. and 2. The posts of the loom, of which two are visible, are distinguished by AA, and the connecting cross rail, or cape, by BB. The roller, or beam, upon which the warp is rolled, appears at C; and the balance weights, by which the tension of the warp is preserved, are at D. The receiving roller, upon which the cloth is wound when woven, is at E; the heddles are at F, and the treddles, or moving levers, are below at G. In Fig. 1. the treddle is represented as having its centre of motion nearly under the weaver's feet, as is customary in most species of light texture. In Fig 2. the centre of motion is reversed, so that the pressure of the foot may operate on the extremity of the lever to increase the mechanical power. In crossed textures the latter is the most advantageous way of applying the power; for although the warp itself be light, and such as would oppose little resistance to the power of rising and sinking in parallel lines, the physical resistance which the cross rings oppose to the moving power, requires a great additional impulse to overcome it. The reversed treddles, therefore, are commonly adopted with evident propriety.

The heddles being the part of the apparatus by which the necessary motions are communicated to the warp, upon their construction depends all the varieties of texture, and those employed for crossing being very different from all others, it becomes an object of the first importance to every person who wishes to acquire a competent knowledge of this branch of the art, either theoretically or practically, to be well acquainted with the nature of their construction. In general, for the coarser kinds of cross weaving, the common linked or clasped heddle is employed; and the difference consists in no alteration of the heddle itself, but in the way in which the warp is drawn through it, and the addition which it is necessary to make, in order to fit it for the special end to which it is to be applied. In some kinds the heddles are made with eyes knotted in them; and where the friction is very great, in consequence of the crossings, perforated beads of smooth round glass are used, both for convenience and durability. Besides the heddle, a second apparatus similar to it is used; and this, whether with or without a bead, receives and conducts the warp thread in its various crossings. In the most common kinds of linau and catgut, it is merely one half, or one link of the common clasped heddle, and is stretched upon a single shaft of wood. These, in the figures, are distinguished by the numerals 1 and 2. By inspection it will be seen that the linau, or gauze mounting, consists of four leaves of complete heddles, marked F, and called standards, and the half leaves 1 and 2. The warp of a gauze is not drawn between the links as in common weaving, so that it may be either raised or sunk, but above or below the clasp, so that the motion of the heddle affects it only in one direction. Thus the thread which is above may be raised, but cannot be sunk by the heddle through which it is drawn, and, *vice versa*, the same takes place with that which is drawn below the clasp. These heddles, or standards, are distinguished by the numerals 3, 4, 5, 6, in both figures. In the standards 3 and 4, which are in front, the warp does not pass at all through any part of the standard, but the half leaf 1 passes above the clasp through each heddle of the standard 3, and through this half heddle the warp thread is drawn. As this half leaf rises independently of the standard, but never sinks unless in conjunction with it, the shaft is below and in front of both standards. The motion of the half leaf 2 being exactly the reverse of the former, the shaft is placed above. Between the standards 3, 4, and the leaves 5, 6, a greater distance is allowed than could conveniently take place in the figure, and here the two threads of warp, which are contiguous, are crossed over each other, instead of being drawn parallel as in other kinds of weaving, that to the left hand being generally above, and that to the right hand below, although this is merely the common form for the sake of convenience, for the order of every part might be inverted, and the same effect would still be produced. When the half leaves are raised and sunk, the warp is parallel like that of common weaving, excepting the cross which takes place between the standards, and when they are kept tight the warp is twisted like a rope. It will be apparent by an attentive inspection of Fig. 1. that the front standard or leaf 3 is sunk, and the half leaf raised to admit the warp thread between the half heddle or *lam* and the standard, and that the reverse takes place with the standard 4, which is raised, the half heddle 2 being sunk. These standards and half heddles in this case communicate no motion to the warp, but merely yield to it, or rather are removed to prevent them from opposing any impediment or resistance. The whole effect upon the warp is here produced by the raising of the back leaf 5, and by the sinking of the back leaf 6. The effect therefore is exactly that of a plain warp operated upon by two leaves of heddles; for the warp is open entirely back to the rods at 7. This may in one sense be called the open *shed*, and in another the cross; for when viewed in a perpendicular direction, as in the figure, all the warp appears open to the eye, although it is really horizontally crossed between the leaves 5, 6, and the standards 3, 4. Thus the leaves 5 and 6 produce the whole motion in this figure, and the reversed and twisted motion will immediately appear by an examination of Fig 2. Here the former motion is completely inverted, and the back leaves 5 and 6 have, in this instance, nothing to do but to preserve the cross given by the mode of drawing the warp. They therefore remain stationary and inactive, while the whole operation is performed by the mounting in front. The cross upon the warp now becomes apparent between 4 and 5, and the whole motion is given by the half leaves or lams 1 and 2, and by the standards 3 and 4. The lams and standards do not now yield in opposite directions, but the lams being pulled tight, the standards act merely like common heddles. The lams no longer yielding to receive the thread between them and the standard, the threads must rise on the opposite side from what they did before, and the same standards being still raised and sunk, one complete twist or revolution of the warp is effected. When this has been secured by the insertion of a thread of woof, the warp reverting to its former state, at the next operation, again twists the threads in the opposite direction, and so on alternately, so long as the texture continues.

Plate CCXIX. Fig. 2.

It is often considered to be useful, occasionally, to intersperse plain parallel woven cloth with the linau. To effect this it is merely necessary to add a third treddle, to reverse the standards without slackening the lams. In this case the standard 4 sinks, the standard 3 rises, and the lams retaining their tension, plain parallel woven cloth is produced, the twist behind and the back leaves 5 and 6 remaining stationary and unmoved. The tension of the lams is produced by hanging small weights on the marches which give motion to them, and connecting these weights with the other marches which move in an opposite direction when they are to be lifted. As the marches are long and short, as in the other kinds of ornamental weaving, the application of the weights is a matter of the utmost facility after the loom is mounted.

Plate CCXIX. Fig. 3, 4.

The Figs. 3 and 4 represent the machinery of crossed texture, where the twist is carried one half further than in common linau or gauze. In this species of cloth, which is called catgut, one revolution and a half is in each twining, and therefore the threads are alternately raised and sunk in the twining and untwining. The stuff commonly employed in the texture of catgut is linen thread, and it is used for stiffening those parts of female dress where transparency is required, as buckram is used for the same purpose in men's clothes. The open *shed* is represented in Fig. 3, and the same letters express the same parts of the loom as in the other figures. The mounting, it will be observed, consists of only three leaves and one lam. Indeed, the coarser kinds may be, and frequently are, wrought simply with two leaves of heddles, and a set of lams hung from a shaft above, without any leaf or standard whatever. In the open state, Fig. 3, the shed is formed by raising the leaf 3, and sinking the leaf 4; the standard 2, under the clasp of which the lam passes, remaining stationary, and the lams slack, as represented in the figure. It then passes round the lower thread, and allows the upper to rise. The reverse shed is represented in Fig. 4. Here the lam being tightened, and the back leaves raised a little, the common gauze twist would be given without further apparatus; but when this is effected, the front standard 2, by sinking, gives the additional half-crossing, and thus all that was required is produced. This being merely a small addition to the general principle of gauze, it is presumed that a tolerably correct conception of it may be formed without the necessity of a more detailed explanation. It will therefore be best to proceed to some explanation of the most common species of loom net-work, for which purpose three have been selected as specimens. The variety is unbounded; but of all the nets in common use, the whole are little else than small additions to, or alterations of, the principle of the first represented by Figs. 5 and 6; and the last, which is called the patent net, though we believe without any just reason, partly because it is one of the most complicated, and also because it is the only one of real British origin, having been invented at Paisley, where it is known by the name of the *night thought*, a name probably bestowed upon it from the nocturnal meditation which it cost the inventor.

Fig. 5, 6.

As the crossings of this last net are very complex, we have only been able to give a general idea of them, which will be sufficient, however, to elucidate the principle to one conversant with the general subject, and even enable any person, with a little care, to form a general idea of its nature. The Figs. 5. and 6. containing the principles of a net which, in combination with the gauze already described, forms the basis of almost every variety in common use, is entitled to a more ample explanation, although it cannot be expected, that this can be rendered sufficiently diffuse to comprehend all that might be practically useful.

The mounting of nets is in so far different from every other kind of weaving whatever, that to effect the purpose, it is necessary that a considerable part of the apparatus should be placed in front of the reed, and should move along with the oscillatory vibration of the lay which contains it. The Figures 5. and 6. are transverse elevations of a loom taken in the front, behind the place where the weaver sits. It may also be proper, in order to prevent the possibility of misconception, to observe, that the heddles are drawn upon a scale vastly greater than their relative dimensions to the size of the loom would warrant. But as the object of the Figure is to elucidate the nature of their construction, this inaccuracy was unavoidable, unless the whole Figure had been drawn upon a very large scale. The reader, however, may avail himself of this caution, that what appears in the Figure to occupy the whole breadth of a loom, does not in actual practice contain much more than the eighth part of an inch, and that the whole breadth is composed of successive repetitions of the same objects. This mode of drawing appeared indispensible, in order to convey a definite idea of the crossings, without enlarging the whole figure to an inconvenient or perhaps impracticable size. Taking Figs. 5. and 6. as transverse elevations of the front of two looms, the fore part of all the apparatus for moving the heddles becomes distinctly visible, and the arrangement of the levers, next to that of the crossings, is the most essential point in which the construction of net looms differs from those adapted for other kinds of fanciful loom-work. Although the distinguishing letters have been applied as nearly as possible to the same parts as formerly, yet as this elevation exhibits the loom in a different point of view, it may be proper to recapitulate the whole, which are as follow: AA the two upright posts which are visible; BB the ends of the upper rails or caps; C, D, E and G are not visible in this view of the loom; F shews the heddles, the front or under *lams* being distinguished by the numerals 1. 1. &c. and the upper or back *lams* by the numerals 2. 2. &c. At H is the front top lever, the others being behind; I and K are the long and short marches, entirely the same in construction with those of other fancy looms, their centres of motion being at L; and, as usual, the short set sinking the leaves by direct communication with the lower shaft, and the long ones raising them by connection with the top levers. The crossings are effected by the mode in which every thread of warp is conducted through the heddles; and this we shall endeavour to render as explicit as possible, although this will be difficult without additional plans. The first crossing is effected exactly as in common gauze, by crossing the two threads which pass through the same interval of the reed; and this takes place when the lams are slack, the crossing being effected by the leaves behind the reed. But as the same threads are not again to cross each other, which would produce plain gauze, the next crossing is effected upon threads contiguous indeed to each other, but placed in different intervals. Thus, if we suppose eight contiguous threads occupying four intervals of the reed to be expressed by the letters AB, CD, EF, GH, the first or gauze crossing may be pretty well understood by the punctuation, A and B being crossed together, CD the same, and so on. Now, this being the first crossing, the second in order, to form a diamond, must stand thus, A, BC, DE, FG, H. This makes it apparent that the diamond is formed; and if we suppose a great series expressed by the same letters, AH will link together like

Plate CCXIX. Figs. 5, 6.

Plate CCXIX. Figs. 5, 6.

the rest, for A will be linked with H of the preceding series, and H with A of the succeeding one. To illustrate this, the letters *abcdefgh* are added to the Figures, and what is termed low-case letters are used to prevent their being confounded with the capitals, which distinguish other parts of the loom. The first mode of punctuation is that produced by the apparatus when in the state represented by Fig. 5. and the second that which it assumes in Fig. 6. From even this cursory description, an attentive examination may satisfy the reader that this apparatus is merely an alteration of the disposition of that of common linau or gauze. The alteration is effected by crossing alternate threads instead of twisting and untwisting the same in rotation. The appearance of the net when finished is a diamond exactly like a common fishing net, and it is represented in Plate CXCIII. illustrative of the geometrical principles of texture attached to the article CLOTH *Manufacture*. In that Plate is also given a representation of what is termed the mail net, which is merely a combination of this net with common gauze. The reader may perhaps be enabled to form some conception of the mounting of the mail net, especially if he be in any respect conversant with the general principles of texture, by supposing it to be merely a double set of gauze mounting, made to work alternately the gauze and net parts. Referring to Figs. 1. and 2. of this Plate, and combining the apparatus represented there with that in Figs. 5. and 6. will also be of service to aid him. Let him suppose Fig. 1. to contain two warps, entirely separate and distinct from each other, and rolled on separate rollers or beams. Let that comprehending the gauze part be represented, as before, rolled on the beam C, and that which composes the whip upon the additional beam N, placed below, and represented by a dotted circle. The two warps being thus kept entirely distinct, that which is below may be slackened whenever the crossing of the whip becomes necessary, without at all affecting the gauze warp upon the beam above, which retains its tension while the other is slackened to admit of the crossing. The number of leaves must be precisely doubled, one set being allowed for the warp on each beam, and the disposition of these leaves is as follows: To the back leaves, 5 and 6, are added two other back leaves exactly similar to those represented. Of these four back leaves, two contain the gauze and two the whip part. In front of these are two standards, with lams exactly, as represented at 3 and 4, these complete the gauze part. The reed comes next, and through it are drawn two threads of each warp alternately. In front of the reed come the additional standards and lams for the whip part, and these are exactly similar to the former. The profile view in Figs. 1. and 2. repeated, gives that view of them, and the front view is the same as in Figs. 5. 6. The appearance of the net when woven is given in Plate CXCIII. attached to the article CLOTH *Manufacture* already quoted, and is the same as that exhibited in Fig. 8. were all the squares filled with diagonal lines. The slackening of the lower beam is effected by the lever P, at the extremity of which are two cords, one of which lifts a catch out of a ratchet wheel on the end of the lower beam, and the other slackens the yarn by turning the beam round which it is wound. The other end of the lever P is connected by a cord, with an additional long march hung below for the purpose, and this march being connected with one of the treddles, operates on the lever when required.

Plate CXCIII.

Plate CCXIX. Fig. 8.

Figs. 7, 8.

The patent net represented in Figs. 7. and 8. is another extension of the principle of the mail net, and the difference of appearance consists merely in the omission of the crossing in every alternate square. This net, we have mentioned, was invented at Paisley, and is almost the only variety which has originated in Britain. The difference is entirely in the disposition of the leaves of heddles, and in the rotation in which they are elevated and depressed. The gauze and whip parts are interspersed in an order to suit the pattern, and which will be easily imitated by taking the black dots for the whip or net parts which form the diagonals, and the white dots for the gauze parts. As all the parts are not slackened at once, four distinct beams or rollers are used, each being slackened in its turn. Fig. 7. exhibits the crossings of one range, which is repeated over the whole web. By comparing the crossings of the lams in Fig. 7. with the appearance of the cloth, which in Fig. 8. is represented as unwinding from the beam in a finished state, a pretty accurate conception of the effect produced by the mounting may be formed. The diagonal crossing of one square being included between the numerals 1 and 2, and that of a second between 3 and 4. When the cross lams, which are here exhibited in their slack state, are tightened, the warp will be crossed and interwoven with the gauze, represented by the white dots. This, therefore, forms one range of squares or checkers, with a diagonal crossing in the bosom of every alternate square. When one range is completed, the intermediate crossing between 5 and 6 is set in motion in the same way, and a similar crossing being continued along the whole fabric, the checkers are alternately crossed and blank. For this operation, therefore, four treddles are necessary; two being allotted for each set of the crossings, and each pair is put in motion alternately.

Plate CCXIX. Figs. 7, 8.

Cursory and brief as the preceding explanations are, they may enable even those who study mechanics only as a matter of speculative curiosity, to form some notion of the construction of this curious and hitherto almost uninvestigated branch of their application. It is indeed singular to reflect, that while the construction of almost every engine in other professions has been repeatedly treated of in almost numberless books, there hardly exists a vestige of enquiry into the principles of the staple manufacture of the three kingdoms, and by much the most extensively practised mechanical art in every part both of Europe and Asia, where mechanical improvement has made any progress.

We have already adverted to the Russian table rubber, as an extraordinary instance of mechanical ingenuity, being more extensively employed in a rude country, and upon a coarse and cheap material, than in all the variegated patterns which have occupied the looms employed in fabricating the most costly silks of France and Italy in that description of work. The knowledge of it, as has been stated, does not appear to have ever reached this country. The author of this article shall therefore mention the way in which the plan which he has given of it came into his possession. A considerable number of years ago, whilst he was devoting much of his attention to trace the various ramifications of this extensive but neglected art, a friend, who, besides being extensively engaged in the professional business of manufacturing, possessed a great taste and indefatigable curiosity to analyse the scientific principles of the art, put into his hands a manuscript book, which he had been many years in filling with such remarks upon the art, as had either occurred to himself, or been obtained from a great number of experienced weavers with whom he had conversed on

Cross Texture.

the various branches of the art. Among many curious and valuable articles relative to a great variety of fanciful work, he was surprised to find a drawing of an apparatus for weaving the Russian rubber, which he had always understood to be totally unknown in Britain. Upon inquiry, he was informed, that a very ingenious man, who had been employed in various departments of fanciful weaving, had turned his attention to the subject as a matter of curiosity, and after carefully examining many specimens of the cloth, and using every means to analyze the nature of its fabric, had, partly from his own invention, and partly from such imperfect hints as he could obtain, arranged a small apparatus, which, upon trial, produced exactly the desired effect. From this apparatus, the sketch which he had copied into his book was taken. The general principle of this sketch will be found in Plate CCXX. Fig. 3.

Plate CCXX. Fig. 1.

In Fig. 1. will be found a sketch, which may be supposed to represent the front elevation of a loom, exhibiting the reed and lay in front. Through the reed at certain intervals, which are here represented by every third division, pass a number of those twines which we have already distinguished by the term *lams*, (probably derived from *lamina*,) to the end of which is attached a glass bead. These lams are five in number, that being the number of successive crossings in this curious specimen of crossed texture; and as the same thread is to be crossed five successive times in the same direction, before it begins to return, the whole five lams terminate in the same bead. The other extremity of each lam is attached to a horizontal wooden shaft, of which, consequently, these must be five in number, and these are suspended between the reed and heddles, so that each may be raised successively by a treddle below, of which consequently there must also be five. The lams are numbered 1, 2, 3, 4, and 5, and the bead appears at *a*. The successive dots diagonally marked along the reed B B, may be supposed to represent the warp when the loom is at rest, and when it is but little opened. All the other parts of the apparatus may be supposed to resemble that of other looms for plain work, and is therefore omitted. The shafts for the lams appear above at C, and the treddles below at D, the intermediate marches being, like the other parts, omitted, and the connections supposed to be made directly from the lam shafts to the spring staves E, and from thence to the treddles. The profile is represented by Fig. 2. to show how the apparatus will then appear; and here the shafts for the five lams at C appear very distinctly, the whole terminating below in one bead, and numbered, as the lams were in the former Figure, from 1 to 5. The heddles appear here at F, and the beams of which, to allow for the crossing there, must be 2 at G and H.

Fig. 2.

Fig. 3.

But in order to represent each successive stage of the operation of the lams, a general plan is given in Fig. 3. where may be seen at one view the whole, from one extremity of the crossing to the other, and for this purpose the Figure is divided by vertical lines into six compartments. The letters AB may be supposed to represent the lay and reed with its divisions; CC denote the place where the lam shafts are hung when not elevated, and DD the shafts in a state of elevation. As the peculiarity of this species of weaving consists in one thread undergoing five successive crossings in the same direction, the six divisions of the figure exhibit it in each of the six changes which it undergoes, and then it may be supposed to return to the point from whence it set out in an inverted succession. Besides this, as the weaving of the cloth is progressively advancing during the whole of the operation, the form upon the cloth, if the changes (as is usually the case) be at regular intervals, will be that of a diamond; and if irregularly disposed, almost every variety of figure, depending upon the resolution of two forces at right angles to each other into oblique ones, may be produced. The shaft CC, in its lowest state, may be supposed the first, or that which is distinguished by the numeral 1 in Fig. 2. excepting in the second compartment, when it is elevated, and consequently that which is behind it, or No. 2. appears in front. In the elevated state at DD, every shaft is supposed to be cut away, so that each appears in its turn, and is distinguished by the reference below. The twines or lams are also successively distinguished by numerals from 1 to 5, and the effect of each, by a short explanation, will be easily discernible.

Plate CCXX. Fig. 3.

1st Compartment. All the shafts are here represented as sunk, and consequently all the lams are slack. The thread upon which the whole operate is that nearest to the left side of the Figure, and is now in its natural and parallel state in the warp.

1st Crossing. The shaft 1 being now drawn up, and the lam attached to it tightened, (the thread which it conducts being also proportionally slackened), the lam is pulled under four threads, and then rises in a new place. If the warp is now opened by the treddles, and a thread of woof inserted, that thread passing under the crossed one, will retain it in its new place, but in its natural exertion to return to its former state, the warp which opposes it will be forced together, and a small circular aperture formed bisected as by a diameter line by the thread of woof.

3d Crossing. The first shaft being now sunk again to its former place, and the second shaft raised, the second crossing takes place, four threads being again crossed further to the left. The crossed thread having now deviated still further from its parallel state, the beam upon which it is wound must be proportionally slackened, to give scope for its divergence from the straight line.

3d, 4th, and 5th Crossing. In all these no difference arises, excepting in lowering the shaft, which has already performed its office, and raising that which is next to be brought into action, and thus the operation proceeds until the fifth crossing has been completed; when, according to this plan, the crossed thread has attained its utmost range, although, were the expence of the apparatus not to preclude it, a continuation upon the same principle might continue the same succession in a diagonal line from one side of a web to the other.

To reverse the order of the crossing, it is only necessary to repeat what has been done in an inverted order, when the thread, by the tension of the beam, will revert to its parallel state, as the lams are successively slackened to relieve it.

Whether this be exactly the apparatus used in Russia, we have no means of determining with any degree of precision. The texture of cloth seems in no country to have excited the attention of the philosophical mechanic. In our own, although acknowledged as the staple of the country, and as a most important branch of both its foreign and internal traffic; although deemed of such national importance as to give name to the second chair of dignity in the kingdom, (the woolsack), it is only regarded by men of science as an object of very inferior importance, by statesmen as an article of revenue, and by merchants as a finished branch of commerce. From what has been said of this particular variety, it must be apparent, that it affords scope for a very great extension of the variety of our ornamental manufacture. The principal objection to its adoption seems to rest upon the great extent of the crossing to which the warp is subjected. In the coarse linen fabric to which it is applied, no great difficulty of this kind is likely to occur; for the hemp being a very strong body, capable of bearing much twine, and long in the staple, the coarse yarn spun from it possesses much tenacity. The silk also is very strong, and net work of this kind might be advantageously woven with it. The cotton also, if very well spun, from the finest wool, it is probable might answer very well. The five successive crossings would unquestionably give this net the advantage of great variety over any with which we are acquainted, being in the proportion of 25 changes to four, and hence it seems to open a field for very great improvement in this branch of texture. At present, it is considered as a kind of *Pons Asinorum*, which none of them have ventured to attempt.

Plate CCXX. Figs. 4, 5, 6, 7.

The two Figures 4. and 5. with the small supplementary sketches 6. and 7. relate to a manufacture which may perhaps be considered as not strictly to belong to this article. It is in so far a species of crossed texture, that the figures are formed by crossing a part of the warp, while the rest remains parallel. Goods woven in this way are called lappets; and as it is now unquestionably the cheapest, and consequently one of the most extensive branches of the fanciful manufacture, some account of its principles may, without impropriety, be inserted as the conclusion of this article. Lappets, from whatever quarter the knowledge of them was derived, formed originally in Britain a part of the fanciful manufacture known by the name of silk gauze, the principal seat of which was the town of Paisley. With other branches of that art, they were totally abandoned for some years, and, with very great improvements in the construction of the looms, were again revived in the cotton manufacture. The original plan of weaving lappets was, in some respects, very similar to the apparatus which has just been described, the pattern being formed by bead lams passing through the reed exactly similar to those which it is proposed to employ for the Russian texture. The lappet consists of two warps of different degrees of fineness, one of which forms the ground work or body of the fabric, and the other, which receives the usual appellation of *whip*, is reserved for the ornamental part. The whip, which is much coarser than the body of the web, crosses over the surface of the cloth without being at all interwoven with the warp. If we suppose that three splits of the reed, or six threads of warp, are to be crossed, the whip is then pulled up into the body of the warp by the tension of the lam, and one thread of woof being inserted, secures it there, when it returns to its former place, by slackening that lam and tightening one which pulls in the contrary direction. Thus the whip is alternately pulled from side to side by the alternate operation of the lams; and, like the apparatus of the Russion texture, a number of lams at different intervals are attached to one bead, a zig-zag or diagonal pattern may be formed as the operation proceeds. Again, if the shiftings are not made at regular intervals, but varied, the diagonal line will be often changed, and curves produced, which bear in appearance some analogy either to circular or elliptical figures.

The operation by beads and lams was that by which this manufacture was entirely effected, whilst it was confined to the silk gauzes. But upon its revival in the cotton trade, an improvement, probably the invention of some ingenious, although obscure, operative weaver, whose name has not reached us, entirely superseded the use of the lams, and substituted in its place the ingenious, though simple, apparatus, which will be found by referring to Fig. 4. In this Figure, as usual, the loom is exhibited as an elevation taken in front. The posts are distinguished by AA, the lay and reed by B, and the remaining letters denote the additional apparatus. In the front of the lay, immediately before the reed, and betwixt it and the board upon which the shuttle runs across, is a horizontal flat piece of wood, or what is commonly termed a shaft, which appears at C, placed with its edge up, and suspended by two small cords from the end of a projecting lever, attached to the upper end of each of the swords of the lay, the projection being at right angles behind the lay. The form of these projecting pieces will be more apparent at Z, in the small supplementary Figure 7, where one of them is shown in profile. When the lay is moved back, the end of the projecting lever of course rises, and, by means of the small cord, elevates the shaft C; and when the lay returns to strike home the woof, the shaft again sinks to its former level. In order that the operation of the cord may be in a perpendicular direction, as nearly as the oscillatory motion of the lay will admit, the cords are directed through the eyes of two small staples driven into the lay, and which appear at EE. In the shaft C, at such intervals as the particular disposition of the intended pattern may require, are driven a number of needles made from stout brass wire, flattened a little at one end, and pointed very sharp, that they may rise easily between the warp, without injuring or breaking any of the threads of which it is composed. Near the point of each, a small eyelet hole is also drilled and smoothly countersunk upon each side, to admit and guide the whip thread. From the shaft C is a connection with a small pin at B, by which the shaft and needles may be shifted from side to side in a horizontal direction; and this operation is performed by the thumb of the weaver's left hand, which also works the lay. The shift is performed either to the right or the left when the lay is brought forward, and the needles sunk totally clear of the warp. The distance of each shift is regulated by a small brass rack fixed to the handle B; and the distance of each shift is ascertained by the pressure of a slight spring F, which stops the rack at each notch or division. The alternate rising and sinking of the needles thus produce exactly the same effect that the beads and lams did by the former plan, and the construction is incomparably more simple and easily wrought.

Plate CCXX. Fig 4.

The principle is, however, not only improved, but greatly extended, so as to render it capable of imitating almost every variety of flowers which can be effected by needle-work. The general principle of this improvement and mode of its application, may be pretty accurately understood by referring to Fig. 5. which is also a front elevation of a loom fitted for lappet weaving. The parts of this figure are in general similar to those of the former; but the reed, which should be placed exactly the same way, is omitted to show more clearly the connection subsisting between the handle at B, and the needle shaft at C, by which the shifting motion is com-

municated to the latter. This connection is made merely by a strong wire passing through an eye in the shaft, so as to effect the horizontal without impeding the vertical motion, and is distinguished by G. Instead of the rack, the *quantum* of motion is now regulated by grooves cut in the edge of a wooden wheel, which revolves upon its own axis, and may be attached to any convenient part of the sword of the lay. That which is here represented, is placed below merely for the sake of conveniency, as many weavers use them above the level of the cloth and warp. The wheel is represented at the letter D, and as much of it appears as can be visible, the remainder being concealed by the intervention of the other apparatus and the posts of the loom. A piece of wood or metal H, being screwed to the needle-shaft, a small cross pin in its lower extremity enters into a groove cut in the flat side of the wheel D; and the pressure of this pin upon the wheel at either side of the groove, regulates the extent of the shift at either extremity. The revolution of the wheel is effected by a small catch pulling the rachet on the circumference of the wheel D, by means of a cord attached to the extremity of the same lever, which elevates the needle shaft. The groove in D being cut suitably for the pattern intended, a fresh part is presented to the pin H, when every successive shift takes place, and thus any pattern may be formed. The groove is cut from the common design paper described in the general article Cloth Manufacture; and the whole art of marking it out consisting merely in transferring the straight lines of which the design paper consists, so as to suit the circular form of the wheel, the following brief directions may perhaps be deemed sufficient for that purpose if carefully studied.

Plate CCXX. Fig. 5.

If the pattern be drawn upon design paper to cover six threads, these six threads may be represented by three divisions of the design paper, or any number may be taken at pleasure, according to the range of the pattern. To transfer the pattern, the wheel must be marked by the following rules:

1st, Divide the circumference of the wheel into as many equal parts as crossings of the whip are required to complete the figure or figures intended by one revolution. Draw radii from the centre to the circumference, and cut the rachet into as many teeth as there are radii. This part of the operation is to be executed, by counting the spaces on the design from top to bottom, and ascertains the number of crossings in the whole design.

2d, Describe a series of concentric circles, equal to the number of spaces included by the pattern from right to left upon the design, and the divisions will be completed.

Now, as the radii diverging from the centre represent the number of shifts, it is only necessary to ascertain the breadth of each; and these may be found by counting the number of spaces on the design, and marking off the same number of concentric circles on the wheel, and joining the marks by oblique lines, and the limits of the groove will be marked, to which must be added, a space equal to the diameter of the pin which is to work in the groove. The groove being then cut between the marks to a convenient depth, the wheel will be complete, and may contain any number of flowers, either similar, or dissimilar that the projector pleases.

When the pattern is so disposed, it is proper to have an easy and expeditious way of disengaging the needle shaft from the lay, so that it may remain at rest while the interval is wrought plain. This is effected in various ways; and as it differs in no respect from the many well known plans for engaging and disengaging machinery of many different kinds, it is unnecessary to go into detail about it in this place.

The last extension of this species of weaving consists in using a number of different frames at the same time; and as this is only a very obvious extension of the same principle, a few cursory remarks may be sufficient.

The common double frame lappet is wrought with two shafts or frames, by means of a rack, as already described. This apparatus merely doubles and inverts the pattern, and all the additional apparatus consists merely of another frame of needles parallel to the first. From the extremity of the first frame, which is acted upon by the rack, a small cord is taken over a pulley, and tied to the second. A small weight hung from the other extremity of the second frame, by a cord passing over a pulley, preserves the tension of the connecting cord, and, by its own gravity, moves the frame in an inverted direction to the former. By the wheel, a boundless variety might be produced; for were a number of wheels placed upon the same axis, to operate at the same time upon distinct and independent frames, not even the complicated machinery of the draw-loom could be rendered productive of greater effect. Upon the whole, the application of the traverse wheel to the art of weaving, though still very imperfectly understood by the operative weavers, who alone employ their talents for the improvement of the manufacture, is the engine to which the intelligent mechanic may rationally look, both for the extension, improvement, and simplification of his machinery in every branch of the art. CROTCHEY, or Corachie, a sea-port town of Persia, in the province of Scind. It is situated 17 miles east by south of Cape Monze, at the head of a bay, which affords good shelter for shipping, and about a mile from the side of a small creek, which can admit only boats. This town is known by several little islands to the northward, and by a white pagoda, built upon a promontory, which bounds the west side of the harbour, and resembles an island when seen from a distance. Vessels enter the bay between the promontory and the largest island. In order to anchor in the outside road, and to avoid the foul ground, the pagoda must be brought to bear N. W. by N. From this anchorage the town is six miles distant. The harbour is defended on the western point of its entrance by a castle, built in 1801, on which are mounted a few pieces of unserviceable cannon. The streets of the town are narrow and filthy, and the houses, which are built of mud and straw, with flat roofs of the same materials, are fitted only to afford shelter from the sun.

Owing to the nature of the soil, which is sandy and stony, there are almost no vegetables for 40 miles round. The soil may be cultivated during the rains. A few date trees, which never bring their fruit to perfection, grow in the immediate neighbourhood of the town; and lemons, mangoes, grapes, plantains, as well as water, and musk melons, are produced; but the only vegetables are a small quantity of carrots, radishes, pumpkins, and brinjal. The water is brackish. Fuel and forage are scarce. The necessaries of life are however cheap; poultry, black cattle, sheep, and goats being very reasonable; and the country abounds with wild geese, ducks, teal, partridges, snipes, hares, and deer. The country is entirely destitute of timber, and what is needed for building boats and houses is brought from Malabar and Bombay.

Crotchey formerly belonged to the Bloaches; but it was given in exchange for some other place to the Prince of Scindy, who found it a convenient part for the caravans from the inland countries. As the branches of the Indus are too wide and deep for the camels to pass, the caravans are no longer able to come from the interior to Tatta; and on this account the trade of Crotchey is greatly increased.

The imports to Crotchey from Surat, Bombay, Muscat, and the Malabar coast, are,

Betel nut,	Nutmegs,
Cardamums,	Pepper,
Cochineal,	Piece goods,
Cloves,	Rice,
Cloths,	Sandal wood,
China ware,	Japan wood,
Cassia lignea,	Saffron,
Copper,	Steel,
Elephant's teeth,	Sugar,
Iron bars,	Timber,
Iron goods,	Tin,
Lead,	Tutenague,
Looking-glasses,	Vermilion.

By means of the caravans from Cabal and Candahar, they bring to Crotchey,

Almonds,	Grain,
Cinnamon seeds,	Hides,
Dates,	Oil, and
Ghee,	Piece goods.

The exports from Crotchey, which are conveyed in the fair season in dingees, (small coasting vessels, with one mast and a high stern,) to Bombay, Guzerat, and the coast of Malabar, consist of the preceding articles and cotton. Since the trade of Laribunder has declined, in consequence of the shoals, by which the navigation of the river is obstructed, the revenue arising from the customs amounts to 125,000 rupees annually. The population of Crotchey is about 9,000, the majority of whom are Hindoo merchants and mechanics. Crotchey is 57 miles from Tatta, and is situated in East Long. 67° 16′, and North Lat. 24° 51′ 15″. See Milburn's *Oriental Commerce*, vol. i. p. 145, 146; and Macdonald Kinneir's *Geographical Memoir of the Persian Empire*, p. 232. (π)

CRUCIFIXION, a mode of inflicting capital punishment, by affixing criminals to a wooden cross. This was a frequent punishment among the ancients, and practised by most of the nations whose history has reached our knowledge: It is now chiefly confined to the Mahometans.

There were different kinds of crosses, though it cannot be affirmed which was in general use; such as that most familiar to us, consisting of two beams at right angles, and St Andrew's cross. Thus Seneca remarks, '*Video istic cruces non unius quidem generis sed aliter ab aliis fabricatas.*' St Jerome and Isodorus allude to both of the preceding, and Augustine describes the cross on which Jesus Christ suffered as the common cross, but it does not appear on what authority, and a he lived in the fourth century, his information must have been derived from others. Some succeeding authors have also supposed that his feet were fixed to a projection, or bracket below, so that he was crucified in a standing posture, to which the same remark applies. Deviations from the ordinary form and proportions were adopted on particular occasions: accordingly Suetonius relates, that while Galba governed a province, he condemned a guardian to crucifixion, who had poisoned his ward in hopes of succeeding to his fortune. But the delinquent claiming exemption from this punishment, as not appropriated for a Roman citizen, Galba, that it might be less degrading, ordered a cross much larger than usual, and also whitened over, to be made for him, *quasi solatio et honore aliquo pœnam levaturus.* It is necessary to observe, that the numerous and diversified crosses and crucifixes exhibited in sculpture and painting are entirely fictitious. These were gradually introduced as the cross itself became an object of superstitious veneration, and when the devout conceived that their salvation was promoted by constantly introducing some allusion to it. Thus it became an universal emblem of piety among them; and crossing the legs of an effigy on a tomb-stone denoted that a Christian was interred below.

On condemnation, the criminal, by aggravated barbarity, was scourged before suffering death; and perhaps this part of his punishment was scarcely inferior to the other. The scourge was formed of cords armed with bits of lead or bone; or it consisted of simple rods of iron and wood, which latter were called scorpions, when covered with spines. While he suffered, he was bound to a column; and that where Christ underwent scourging, was still extant during the days of St Jerome in the fifth century. This being the common custom, and preceding not only crucifixion, but other kinds of capital punishment, it is an error to suppose that Pilate scourged Christ from motives of greater severity towards him. Indeed, it is rather to be inferred from the whole text of Scripture, that he yielded to popular clamour in consigning him to the Jews. Scourging seems to have been the prelude of death. Thus Quintus Curtius relates, that a band of Sogdians long resisted the progress of Alexander the Great, by taking possession of a cave situated high in a lofty mountain of Asia; but that prince resolving to conquer them, selected 300 men from his army, who had been accustomed to a pastoral life, in rocky and precipitous countries, and whom he induced, by the promise of ample rewards, to ascend the mountain. This they at length accomplished with the loss of many of their number, and speedily finding a way behind the cave, appeared on a pinnacle above it. The Sogdian general, dreading the consequences of their success, ineffectually endeavoured to obtain terms of capitulation, but being compelled to surrender at discretion, he descended from his stronghold, accompanied by his relatives and principal officers. Alexander, by this means, having got them into his power, instead of respecting their bravery as it merited, inhumanly ordered them to be scourged and crucified around the foot of the rock, *quos omnes verberibus affectos sub ipsis radicibus petræ crucibus jussit affigi.* The

Jews captured by Titus at the siege of Jerusalem, were scourged and tortured previous to crucifixion. Anthony scourged Antigonus king of Judæa, which Dio the historian affirms, had never before been done by the Romans to a sovereign, and then beheaded him. That aggravation of severity in the execution of a capital sentence, universal in ancient times, and still practised by barbarians, is justly reprobated by the modern criminal code of civilized nations.

The criminal was compelled to carry his own cross to the place of execution, which was generally at some distance from the habitations of men. This is still the custom in several countries with respect to their capital punishments; and it is probable that inflicting these within the walls of cities was less frequent of old than it is now. A certain gate had its specific name from being the exit of criminals on the way to punishment. It was not the whole cross, according to some, which was borne by the offender, but only the transverse beam, or patibulum, because they suppose the upright part to have remained stationary in the ground, whereas the other was moveable. One of the Roman classics says, *Patibulum ferant per urbem et cruci affigantur*. However, circumstances shew that this could not have been the uniform custom. The criminal, if tardy, was urged along by an iron goad, or stripes; and it is likely that in Rome, either the cross was hung with bells, or that the executioner, ringing a hand bell, preceded it. Formerly it was thought ominous to meet a criminal about to suffer; and a Roman priest or magistrate was polluted by the sight of a dead body, insomuch that certain ceremonies of purification were required before either was entitled to discharge his respective functions. Bells were therefore rung as a warning for all those to remove who might be exposed to contamination; and in the triumph of a victorious general, we are told, that the captives were carried along *dependentibus aliquot tintinnabulis quorum sonitu obvii moverentur, ut devoti et jam funesti corporis contactu abstinerent.*

The criminal having reached the fatal spot, was stripped nearly naked, and affixed to the cross by an iron spike, driven through each hand and each foot, or through the wrists and ankles. Authors are, nevertheless, greatly divided concerning the number and position of the nails in ancient punishments; and it has been conjectured, that in the most simple crucifixion, whereby both hands were nailed above the criminal, and both feet below, all on one perpendicular post or tree, only two were used. The sounder opinion, and that which coincides with modern practice, bestows a nail on each member; and although the following passage is employed in a ludicrous sense, it sufficiently indicates the truth.

> *Ego dabo ei talentum, primus qui in crucem excurrerit*
> *Sed ea lege, ut affigantur bis pedes bis brachia.*
>
> PLAUTUS *Mostellaria.*

That the weight of the body might be the better supported, the arms and legs were encircled by cords, an instance of which occurs in a crucifixion at Algiers, which is thus described by a spectator. "The criminal was nailed to a ladder by iron spikes through his wrists and ankles, in a posture resembling St Andrew's cross, and as if apprehensive that the spikes would not hold from failure of his flesh, the executioners had bound his wrists and ancles with small cords to the ladder. Two days I saw him alive in this torture, and how much longer he lived, I cannot tell."

If the cross consisted of two pieces, it is not unlikely that the hands of the criminal were nailed to the moveable part, or *patibulum*, and that being then elevated along with it by the strength of men, his feet were fixed to the bracket. These facts are extremely obscure, and there is reason to believe, that crucifixion also took place otherwise. From the narrative of a martyrdom, it is evident that the whole cross was on the ground: "He stripped himself of his own accord; then gazing upwards, and rendering thanks to heaven, he extended himself on the cross, so that he might be nailed to it by the executioner; and when fixed, the cross was erected." In like manner, Josephus observes, that "Bassus ordered the cross to be taken down, as he was about to command that Eleazer should immediately be raised on it." And the same is to be inferred from the words of Julius Firmius, an author of the fourth century.

If, instead of being nailed to the cross, the criminal was bound to it by cords, it was designed as a more cruel punishment. Thus in the crucifixion of St Andrew, the proconsul directed the executioner to bind his hands and feet, and suspend him thus, without being fixed by nails, that he might endure the greater torment. Ausonius, in a fabulous narrative, figures a punishment of this description.

> *Eligitur mœsto myrtus notissima luco*
> *Invidiosa Deum pœnis. Cruciaverit illic*
> *Spreta olim, memorem Veneris, Proserpina Adonim,*
> *Hujus in excelso suspensum Stipite Amorem,*
> *Devinctum post terga manus, substrictaque plantis*
> *Vincula mœrentem, nullo moderamine pœnæ*
> *Affigunt.*

The criminal being fixed on the cross, was left to expire in anguish, and his body remained a prey to the birds of the air. His death, however, was not immediate, nor should it be so in general, considering that the vital organs may escape laceration. We learn from the distinct narrative of the evangelists, that conversations could be carried on among those who suffered, or between them and the byestanders: and Justin the historian relates, that Bomilcar, a Carthaginian leader, having been crucified, on an accusation of treason against the state, he bore the cruelty of his countrymen with distinguished fortitude, harangued them from the cross as from a tribunal, and reproached them with their ingratitude, before he expired. There are repeated instances of persons crucified having perished more from hunger than from the severity of the punishment. The Algerine before spoken of, survived at least two days, St Andrew lived two or three, and the martyrs Timotheus and Maura did not die during nine days.

By the Mahometan laws, certain delinquents are to be punished with crucifixion, and killed on the cross by thrusting a spear through their bodies; and here we find an example of what is narrated in scripture, of a soldier piercing the side of Jesus Christ with a lance though he was dead. Among the Jews, we may conclude, from the treatment of the two thieves crucified along with Christ, that it was customary to break the legs of criminals, but whether as a *coup de grace*, like the former, and resembling some modern European punishments, is not evident. It is denied by Lipsius to have been part of the punishment of crucifixion, or attached to it in particular; yet there are passages in Seneca and Pliny which we might rather infer that the reverse was the case, at least with the Romans. Certainly it cannot be considered an effectual means of hastening death. We know, however, that there was a peculiar punishment of this description, and perhaps a capital one, called *crurifrangium* by the ancients, inflicted on Roman slaves and Christian martyrs, as also on women or girls. Augustus ordered the legs of one to be broken who had given up a letter for a bribe; and Ammianus says, " both the Apollinares, father and son, were killed, according to the sentence, by breaking their legs." Under the reign of Dioclesian, twenty-three Christians suffered martyrdom in the same manner. The legs of the criminal were laid on an anvil, and by main force fractured with a heavy hammer, somewhat similar to the modern barbarous custom of breaking the bones of offenders on the wheel by an iron bar. From the narrative of the evangelists, we may conclude, that breaking the legs of the thieves was to promote their death, that they might be taken down the same day from the cross.

That spectators might learn the cause of punishment, a label, or inscription, indicating the crime, frequently surmounted the head of the criminal. The offence charged against Jesus Christ, was having called himself King of the Jews. Accordingly, the inscription on his cross was, " This is Jesus, king of the Jews." By our own customs, a label is sometimes hung from the neck of an offender condemned to lesser punishments, describing his guilt, which is meant to aggravate the ignominy. But among the Romans, this was perhaps also the warrant for putting the sentence in execution. Caligula, at a public feast, ordered the hands of a slave, who had stolen a piece of plate, to be cut off, and hung from his neck, and he was then led round the guests, preceded by a label declaring the cause of punishment. Domitian ordered a person to be taken from the theatre and thrown to the dogs, with a label bearing, " For impious expressions."

That the object of crucifixion might be fulfilled in exposing the body of the criminal to decay, sentinels were commonly posted beside the cross, to prevent it from being taken down and buried. Privation of sepulture was dreaded as the greatest evil by the ancients, who believed that the soul could never rest or enjoy felicity, so long as their mortal remains continued on the earth. Thus, it was a great aggravation of the punishment,

> ———*Scio crucem futuram mihi sepulchrum*
> *Ibi mei majores sunt siti; pater, avos, proavos, abavos.*
> PLAUTUS, Miles Gloriosus.

Perhaps the practice of the Romans was uniform in accomplishing what is expressed in these lines, and, in Petronius Arbiter, it is said of the sentinel, " *Proxima ergo nocte, cum milés qui cruces asservabat, ne quis ad sepulturam corpora detraheret, notasset sibi, et lumen inter monumenta clarius fulgens.*" Whence it appears, that the soldier watched to prevent the removal of the body, which the relatives of the deceased anxiously desired, and, as the same author intimates, succeeded in obtaining. The Jews solicited Pilate to permit the body of Christ to be taken down, because the day subsequent to his crucifixion was a festival; and although the Jewish law in one place says of a criminal, " his body shall not remain all night upon the tree, but thou shalt in any wise bury him that day," it is certain, that on occasions of hostility an enemy was exposed. Seven descendants of Saul having been put to death by the Gibeonites, " Rizpah, the daughter of Aiah, took sackcloth, and spread it for her on the rock, from the beginning of harvest until water dropped upon them out of heaven, and suffered neither the birds of the air to rest on them by day, nor the beasts of the field by night." In proceedings of so arbitrary a nature, and the adoption of customs by nations remote from each other, or living in distant æras, uniformity cannot be thought to prevail. The Mahometan commentators on their own laws are divided concerning the disposal of crucified malefactors; some maintain, that the body should be taken down in three days, others that it should remain on the cross until it decays by the gradual progress of dissolution.

Besides these, the ordinary modes of inflicting the punishment of crucifixion, assuredly sufficiently cruel in themselves, mankind have sought the gratification of vengeance in deviating from them. Such was the conduct of the Roman soldiers under Titus at the siege of Jerusalem, where the miserable Jews were crucified in various postures by their sanguinary enemies. Seneca speaks of crucifixion with the head downwards; and of this we have a noted example in the history of St Peter, during the first century of the Christian æra. Having been seized by the Roman government, and condemned to die on the cross, it is said that he solicited, as a greater degradation, that he might be crucified with his head downwards. Hence Chrysostom exclaims, " Rejoice, O Peter, that you enjoyed the privilege of dying by the cross, and that you desired crucifixion in imitation of your blessed Master, not like him, however, in an upright posture, but with your head downwards, and your feet aloft, as if you had been preparing to journey to heaven." Peter was not a solitary instance; for another martyr, Calliopius, suffered in the same manner: and Eusebius describes the punishment of certain martyrs in Egypt, to have been inverted crucifixion, as an aggravation of punishment.

It appears that delinquents were sometimes affixed to the cross, and burnt or suffocated to death. A Roman emperor commanded that an offender should be treated thus, and suffocated with the smoke of green wood, a crier proclaiming, "Let him who has sold smoke, suffer by smoke." When the executioners prepared to fix Polycarpus to the cross, he requested them to desist, " as without being secured by nails, he who had permitted his death by fire, would endow him with strength to bear it," therefore they only bound him.

With respect to the persons on whom this punishment was inflicted, we have seen that the Carthaginian leaders were not exempt from it; but elswhere, especially among the Jews and Romans, only the lowest malefactors were condemned to the cross. It was peculiarly appropriated for slaves.

> *Pone crucem servo: meruit quo crimine servus*
> *Supplicium?* JUV. *Sat.* v.

The author of the Bellum Hispaniense annexed to Cæsar's Commentaries, says, *Ea nocte speculatores prehensi servi tres et unus ex legione vernacula. Servi in crucem sublati; militi cervices abscissæ*, cap. 20. Crucifixion is always called *servile supplicium* by the Latin writers. Livy also, in speaking of a revolt among the slaves, which Marcus Acilius the prætor marched with an armed force to quell, observes, that many were killed in an encounter, some captured and restored to their owners, but the ringleaders were scourged and crucified; and Augustus crucified thousands at a time in Sicily, who wanted masters. Soldiers, and especially deserters, were subjected to this punishment. It was not, however, the proper punishment of the former, whence Vulcatius apparently reprehends Avidius Cassius, because he ordered soldiers, who had forcibly despoiled the inhabitants of a province of their property, to be crucified on the spot, of delinquency; and it is elsewhere said, "for he crucified soldiers, and subjected them to servile punishments." Fugitives are said, by Valerius Maximus, to be most deserving of crucifixion, *cruce dignissimi fugitivi*, which Livy illustrates in the punishment of deserters thus: *de perfugio gravius quam de fugitivis consultum: Nominis Latini qui erant securi percussi. Romani in crucem sublati.* Thieves and robbers in particular were condemned to crucifixion, of which we have an example in the two thieves mentioned by the evangelists: and Valerius Maximus, in a chapter on *Severity*, relates, that a wild boar of extraordinary size being brought to Lucius Domitius the Roman governor of Sicily, he ordered a shepherd who had killed the animal, to appear before him. An edict having lately been promulgated, that no one should be in possession of a weapon, because the province had been pillaged by robbers, he asked how the shepherd had killed the boar; and on his answering that it was with a boar-spear, ordered him to immediate crucifixion. By the Mussulman laws, a magistrate may condemn certain highway robbers, either to the cross or to lose their hands. But for one robbery, both punishments cannot be inflicted, because by the code of the Mahometans, no single offence can receive a double punishment.

In the destruction of an enemy, in religious persecutions, or popular commotions, it is likely that neither age, sex, nor condition, was respected: and we read of women being condemned to the cross. Eurydice, queen of Ptolemy Philopater having been put to death, and the king passing his time in weakness and debauchery inconsistent with the benefit of the state, a tumult was excited, wherein the courtezans who lived with him were crucified to avenge the fate of his queen: Tiberius also, on a certain occasion of adultery in the temple of Isis, ordered a female called Ida, to be crucified as well as the priests of the temple; and female martyrs suffered in this manner during the persecutions for Christianity. The fortitude of Simeon, a Christian ecclesiastic who was crucified, at the venerable age of one hundred and twenty, has been handed down to the admiration of posterity. But the cross has been made a more terrible instrument of destruction to a vanquished enemy. Thus Alexander the Great, we have already observed, crucified the Sogdian officers and their leader, at the foot of their strong hold; and at a another time, after putting eight or ten thousand Tyrians to the sword on taking their city, he crucified 2000 more along the shores. *Triste deinde spectaculum victoribus ira præbuit regis. Duo millia in quibus occidendis defecerat rabies crucibus affixi per ingens litoris spatium perpenderunt.* Not less sanguinary was the vengeance of the Romans against the Jews; Minutus Alexander crucified 800, and Quinctilius Varus 2000, on account of some revolt. Titus, whom we are wont to esteem as humane and merciful, crucified above 500 in a day; and at the sack of Jerusalem, under his command, the Romans, wherever they could seize the affrighted fugitives, either in hatred or derision, nailed them to crosses about the walls of the city, until the multitude was so great, that room was wanting for the crosses, and crosses for the bodies.

Crucifixion has been considered the most cruel of punishments, and merited by the most atrocious offences only; but the barbarity of mankind has made little distinction in making punishments commensurate with crimes; and condemnation to torture has been dealt with a lavish hand. That the pain of the cross is cruel cannot be denied, yet we are perhaps accustomed to exaggerate it from our unacquaintance with other punishments. Examples are not wanting of persons having been taken down from the cross alive, and surviving the laceration of their members. Josephus the historian relates, that on leaving a particular town in Judea, he saw a great many of the enemy crucified; but it grieved him much to recognize three of the number with whom he had been in intimate habits. He hastened to inform Titus of the fact, who immediately ordered them to be taken down, and their wounds carefully healed. Two nevertheless perished: but the third survived. CRUSADES.

CRUSADES, military expeditions, undertaken by the Christians of Europe, for the deliverance of Judæa from the dominion of the Turks and Saracens. These expeditions, like some which are recorded in the history of the heroic ages of antiquity, shew the power of superstition to inflame the passions, and call forth the energies of the human mind. The mere prosecution of a foolish object may often be productive of greater benefit, than the actual accomplishment of one more judicious. If eagerly pursued, it augments activity by exercise. Even though unattainable, it puts ingenuity to the stretch, and acquaints us with our possession of powers, which may afterwards be better directed; and as chemistry was promoted by a search after the philosopher's stone, the revival of civilisation was accelerated in Europe by a childish contest for a barren mountain in Asia. We shall treat the subject, therefore, as deriving more importance from its moral consequences, than from its historical facts, which differ little from those of other religious wars; and having given a rapid outline of the latter, we shall consider the former at greater length.

About 70 years after the death of Christ, the city of Jerusalem was taken and destroyed by Titus. In the year 130, it was rebuilt by the Emperor Adrian, and the Christians were permitted to return to it. Their establishment, however, was by no means flourishing, till Constantine embraced their faith, when his Empress Helena visited Jerusalem, and having ordered all the places which had been signalized by evangelical events to be cleared of rubbish, inclosed those of the most hallowed sanctity, within the walls of a spacious church. In the latter days of the empire, the decay of reason, which had kept pace with the decline of knowledge, made way for that superstition, which transfers its feelings to the material objects with which they are associated, and a strong desire was consequently felt by the ignorant and zealous Christians, to visit the scenes which were so often in their thoughts. What was at first the indulgence of a sentiment, appeared at last the execution of a duty; and pilgrimages to Palestine became a frequent, because an applauded practice through the whole of Christendom. In 637, Jerusalem was conquered by the Saracens, whom interest induced to continue to the pilgrims a peaceable reception; but this ceased to be the case, when the Turks, in 1065, got possession of the holy city. That wild and ferocious tribe, though superior in force, were inferior in civility to the Saracens of Arabia, and made so little scruple to plunder and insult their Christian visitors, that the dangers of pilgrimage, painted in the most terrific colours, by those who returned from them, began to threaten a discontinuance of this sacred duty. In Europe, at that period, the minds of men were in a state most favourable to be powerfully agitated by tales of outrage, heightened by the impiety of its perpetrators. They were in that stage of intellectual childhood, when passion, prevailing over reason, receives with eagerness every thing that is strange or dreadful, and under the force of its impressions, favours the introduction of the most extravagant opinions. Ignorance was so universal, that the slender knowledge possessed by the clergy enabled them to command a veneration, and acquire an influence, which they did not fail in converting to their own advantage. For this they had a tempting opportunity, the system of civil government being then as imperfect as that of spiritual tyranny was complete. Under the feudal system, every Baron was a petty prince, who acknowledged but a slight allegiance to the sovereign; and, like the members of the German empire, in our own day, granted or withheld his military services, at his own pleasure. In addition, therefore, to the wars of nations, the wars of districts were incessant; and the general character, being a compound of turbulence, animosity, and ignorance, was a desireable subject for the successful application of superstitious terrors, by which it could be persuaded into any sacrifice however great, or roused to any enterprise however perilous. At this period, the papal authority was in its plenitude; and kings, like their subjects, were enslaved to the superior craft of the priesthood. The Roman empire of the East still protracted its feeble existence at Constantinople; but all its Asiatic provinces had fallen under the dominion of the Saracen Caliph, or rather of the Turkish Sultan, who exercised the sovereignty in the character of his delegate.

In this state of things, an ecclesiastic of Amiens, who was afterwards celebrated by the name of Peter the Hermit, returned from Palestine, after suffering exactions and injuries, which he described, at Rome, with such inflammatory pathos, as to awaken the pity, or rather the ambition, of the sovereign Pontiff. Urban II. like his predecessors in the chair, had long cherished a design of repelling the encroachments of Mohammedism, by the arms of Christendom, and thought the eloquence of Peter might be employed as an instrument to gain the co-operation of the European princes. He sent him, therefore, into the different states of Italy and France, where, in sermons, he told his piteous tale with such effect, as drew to his harangues auditors of every rank and of incalculable number. After this preparation of public feeling, Urban assembled a general council at Placentia, which was attended by 4000 clergy and 30,000 laymen, and at which the project of invading Palestine was applauded by all; but the frenzy of the Italian barons was not yet wrought up to such a pitch as seduced any one to embark in it. The experiment was, therefore, repeated; and in a council at Clermont, the superior ardour and impetuosity of the French were shewn by their promptness, not merely to applaud, but to enlist in an expedition, which would both give them an opportunity of signalizing their prowess, and indulging their taste for adventure, and would likewise purchase for the young nobility a papal pardon of the numerous sins with which they were burthened by habitual dissipation. On this occasion, the Pope himself was the preacher, and spoke with such animating effect, that his harangue was interrupted by unanimous shouts from the multitude of "God wills it—God wills it!" His holiness then intimated, that the cross should be the badge of the combatants. This figure was accordingly worn upon their shoulders, and the expedition was named a *croisade*. A crowd of all descriptions enrolled themselves under the banner of Peter the Hermit, who placed himself at the head of 80,000 recruits, with sandals on his feet, and a rope round his middle. The 15th of August, 1096, was fixed for beginning their march, but to the impatient spirit of the zealot army, the day appeared too distant; and 60,000 of them set out from the borders of France and Germany, early in spring, under the guidance of Peter, whom they had compelled to this precipitation of the measure. These were followed by another band of 15 or 20 thousand; and in the rear of all, came a mob of 200,000, who exhibited in their conduct the most singular extremes of fanaticism and vice. The Jews of Germany were their first victims; but their outrages in Hungary and Bulgaria drew upon them a severe retaliation from the inhabitants, and not more than a third part of this undisciplined multitude escaped, with Peter, to Constantinople, where their succour against the Turks was eagerly expected by the Emperor. Tired, however, with their depredations, he persuaded them to proceed into Asia, where they were met by Sultan Solyman, and almost totally destroyed on the plain of Nice; Peter himself and a slender remnant of his frantic host being all that returned to the Byzantine capital.

But though this premature and infatuated swarm of crusaders was thus swept away, the most valuable part of the expedition was still in reserve. Godfrey of Bouillon, Hugh of Vermandois, Raymond of Tholouse, Bohemond and Tancred, with many more of the minor European princes, had, by the sale of their domains, assembled regular and well-appointed armies, which, after the pope had declined an invitation to head them, marched at the appointed time towards Constantinople. These new guests, though somewhat less uncivilized than their brutal precursors, were still extremely troublesome to the Greek emperor. By flattery and address, however, he prevailed on them to pass the Bosphorus; and when reviewed in the neighbourhood of Nice, they amounted to 100,000 horse, and 600,000 foot, among whom the women and followers were included. Provisions for this crowd were supplied by the maritime towns of Italy; and Genoa was indebted for its subsequent importance, to the wealth acquired

Crusades.

in a traffic, which the necessities of the crusaders could not fail to render lucrative. Having taken Nice, and defeated Solyman, in 1097, they proceeded eastward, where Baldwin conquered Edessa, and erected it into a separate principality for himself. In the end of 1098, they took the town, but not the citadel of Antioch; and an army of 600,000 Saracens, which had moved to the relief of the latter, was totally defeated and dispersed by the besiegers. In 1099, the crusaders, with little more than a twentieth part of their original number, advanced to Jerusalem, which, after a siege of forty days, was taken by storm, and all its inhabitants, except the Christians, sacrificed in a general massacre. At this scene of barbarity, Peter was present, in the character of a chaplain, for which he had judiciously exchanged that of a general; but his patron Urban died before the gratifying intelligence could reach him. The heroic Godfrey was raised by the army to the throne of Jerusalem; and in the first, and only year of his reign, he added double security to his conquest, by defeating the Egyptian sultan, with an innumerable army, at Ascalon. He was, notwithstanding, defrauded of the reward of his valour, by a papal legate, whom the clergy elected to the patriarchate of his new kingdom, and who contrived to include the temporal in the spiritual power, leaving to Godfrey only the little principality of Jaffa, and a few immunities in that of Jerusalem. The crusaders, after seeing their object accomplished, began to return to Europe; and the few who remained in the Christian settlements of Jerusalem, Antioch, and Edessa, to which a fourth was added, by erecting the Syrian Tripoli into a domain for the young count of Tholouse, were obliged to depend for defence against the Turks, on the gradual accession of adventurers, whom the fame of their previous exploits allured from Christendom. An army of these recruits, amounting to 200,000, was collected by Hugh, brother of Philip I. king of France; but they never reached their destination, being cut off in hostilities, first with the Greeks, or afterwards with Solyman, who still occupied the open country of Asia Minor.

The Christians, at length, finding themselves surrounded with foes, (for even the emperor, though their liege-lord, viewed them with the same hostility which he had felt for their Moslem predecessors,) supplicated a second crusade, which was preached, in 1146, by Bernard, the sainted founder of the monastic order of Bernardines. His eloquence having persuaded Louis VII. of France, and Conrad III. of Germany, with 300,000 of their subjects, to assume the cross, Conrad took the lead, but was defeated by the Turks near Iconium, and with difficulty escaped to Antioch. Louis, a short time after, suffered a similar fate; and both returned home, after witnessing the ruin of the finest armies which their countries had ever produced. The disastrous issue of these attempts for their relief, only hastened the decline of the Christian principalities in Asia. Adversity created divisions among them, which might have been still more fatal, had not equal discord prevailed among their enemies, which gave the former an opportunity of forming an alliance (1166) with the Saracens of Egypt against the Turks of Syria. This, however, was of short duration; and had it been more permanent, could not have availed to resist the illustrious Saladin, who, about the middle of the 12th century, raised himself, from a humble attendant of the caliphs, to the sovereignty of Persia, Arabia, Syria, and Egypt. The next object of his ambition was the contiguous kingdom of Jerusalem; and in the battle of Tiberias, having defeated its army, and taken Guy of Lusignan, who then wore the crown, he made himself master of the city in 1187. Saladin, however, whose valour was equalled by his generosity and wisdom, though he restored Mohammedism, tolerated Christianity in his new conquest; but a few cities on the coast was all of which the Christians retained an independent possession in the East.

Though, in a rational age, the capture of Jerusalem should not have affected the happiness of Europe; yet as ideal evils are frequently the greatest, it was felt through Christendom as an intolerable calamity, and the Pope (Clement IV.) took advantage of this sensation, to unite its sovereigns in a new crusade. The great thrones of the West were, at this time, occupied by princes of eminent talents, who employed them as the fashion of the age prescribed. Philip the Second of France, Richard the First of England, and the German Emperor Frederick Barbarossa, engaged with much zeal in the expedition; but the last of these princes having defeated the Greeks, who had preferred an alliance with Saladin to one with the crusaders, and having, afterwards, been twice successful against the sultan of Iconium, was drowned accidentally in crossing a river. The French and English kings were more fortunate, and arrived at Ptolemais while besieged by the Asiatic Christians, with a force which, when united with the besiegers, made an army of 300,000 men. Ptolemais was taken, but Philip, disgusted with the real or affected superiority of his rival, returned home; and Richard had the glory of defeating Saladin, undiminished by the claims of a partner. The army, however, being reduced, not more by the usual waste of war, than by those intestine quarrels which are fatal to almost every military coalition, he, like the preceding leaders, returned, unaccompanied even by its remains, to Europe. Judging of others by his own generous nature, he took his way through Austria, though he had quarrelled with its prince in the East, and being arrested, was kept in prison till an immense ransom had been procured from his subjects. Before his departure from Syria, he had made a peace with Saladin, who soon after died.

Notwithstanding the misery which had been the uniform result of the crusades, such was the prevalence of fashion, or the ascendancy of the priesthood, that fresh adventurers were ever ready to renew them. In 1202, Baldwin, Count of Flanders, collected an army to act against the Mohammedans, but began, as usual, with the Christians of Greece. Arriving at Constantinople during a disputed succession, his interference tempted one claimant to assassinate his rival, and Baldwin, after dispatching the survivor by a public execution, and indulging his followers with the plunder of the city, sat down on the imperial throne of the Eastern empire. In this splendid acquisition, it is not surprising that the original object of the crusade was forgotten, and that the adventurers preferred the destruction of their fellow Christians, and the spoils of an empire, to a doubtful contest with the Saracens, and the recovery of a sepulchre. Only a few knights crossed to Asia, and the fourth expedition terminated without a single conquest from those against whom it had been equipped.

The frenzy of Europe, however, continued unabated; and John de Brienne, a young French gentleman, being appointed King of Jerusalem, and taking the aid of the Duke of Austria and the King of Hungary, made a descent on Egypt with 100,000 men, from a hope that, by destroying the power of its sultan (brother to Saladin) at the seat of government, the distant dependency of Jerusalem would fall of course. He was at first successful, and after a long siege took Damietta. But a papal legate insisted on superseding him in the command; and during the delays created by this dispute, his army was surrounded by the inundation of the Nile, and he was forced to purchase a retreat by the cession of his conquests, and the surrender of his person as a hostage. Another of the western emperors now became the leader, and renewed the hopes of the crusaders; but this prince, who engaged in the enterprise entirely from policy, avoided the hazards of war, and got possession of Jerusalem by a treaty with the sultan. It did not, however, remain long in possession of the Christians, for Judea (1244) was overrun by the barbarous Tartars, who fled before the irruption of Jengis, and its maritime towns were all that the crusaders retained.

From this uniform round of enterprise and disaster, which renders the narrative of one crusade almost a transcript from that of another, the zeal for renewing them had begun to languish, when a monarch appeared on the throne of France, in whom the superstition of the age was superadded to every amiable and heroic virtue. This was Louis IX. who, after contenting himself for some time with the proper duties of his office, and labouring for the external security and internal improvement of his kingdom, was at length persuaded that he had been warned by heaven, in a dream, to assume the cross. Resisting, therefore, the entreaties of his family and ministers, and embarking with an immense force in the ports of the Mediterranean, he first touched at Cyprus, and afterwards landed in Egypt. The sultan proposed a treaty, which Louis rejected; and after losing one half of his army by sickness, attacked the Saracens with the remainder, but was defeated and taken, near Massoura, in 1250. During his captivity he was treated with the most generous respect; and having ransomed himself and his followers, he removed from Egypt to Palestine, where he remained for some years, and then returned to his own dominions with the sanguine hope of equipping a new expedition. After his arrival, he again devoted himself to the duties of government, and, by the institution of courts of justice, the encouragement of letters, and a general attention to the happiness and improvement of his subjects, performed a service, and earned a glory, far superior to those which he had relinquished, but which he still unfortunately preferred. His piety was ardent and sincere; but being misled by directors who were either deceitful, or themselves deceived by the prevailing absurdities of opinion, he never ceased to pant after a new crusade.

At length, unable to resist his impatience, he once more sacrificed a real to an imaginary duty, and (1270) embarked with an armament from the south ports of the kingdom. His brother, at that time king of Sicily, whose crafty ambition was equal to the unsuspecting sincerity of Louis, seized the opportunity of turning the spiritual zeal of the crusaders to his own temporal advantage. He pretended to have some pecuniary claims against the king of Tunis, whose dominions he had a secret wish to acquire, and by persuading Louis that he had a fair chance of converting, or compelling that prince to the profession of Christianity, the pious warrior was seduced to make the attempt. Having accordingly landed his army, it encamped near the ruins of Carthage, but was immediately surrounded and besieged by the Moors. A contagious distemper attacked his troops: he caught it himself, and died in the 55th year of his age. This prince was among the last, and was certainly the most to be regretted, of all the victims to crusading fanaticism. Had he lived in a more enlightened age, his personal virtues would have been a blessing to the world, whose misery was augmented by their misdirection. After his death, his brother made peace with the Tunisians, and the skeleton of his army returned to France. Long before the age of St Louis, the appetite for holy wars had declined throughout Europe, and the small number of recruits, who arrived in Palestine, had induced the Christian settlers to intermarry with their Moslem neighbours. The descendants of the crusaders had consequently degenerated into a mixed race, and had almost forgot their slight pretensions to an European origin. They retained only Tyre, and Acre or Ptolemais; the latter of which being taken by Melecseraph, Sultan of Egypt, in 1291, the former also surrendered. Their surviving inhabitants were blended with the Mohammedan population of Syria, and not a vestige of the Christian conquest remained.

Such is a hasty sketch of these famous expeditions, which, although to us rendered more interesting by our descent from their authors, exhibit all the disgusting features of the other religious wars, which deform the history of mankind, and depress our triumph in the excellence of human reason. In each, we find the same ignorance in the popular mind; the same direction of it to a trifling object; the same exaggeration of some imaginary evil; the same devotion of every comfort for its redress; and the same domination of a crafty priesthood, seeking to augment its consequence and authority, by engaging the people in measures of which it was the sole projector and guide. In the crusades, therefore, the historian sees little that is new, and while relating them, only traces afresh a part of the circle which human folly is destined to describe; but to the philosopher, who follows out their consequences, no subject can be richer in materials for speculation. The evils which they created were immediate and obvious; the advantages were more remote, and require demonstration to claim our assent. The crusades caused a waste of life and labour beyond example, without the temptation of any prospective return: they, for two centuries, afflicted almost every family in Europe with the most painful privations; and they alienated the attention of its inhabitants from the improvement or enjoyment of their natural blessings. Agriculture and commerce, arts and education, were neglected by every rank, under a general distemper of the imagination, which represented happiness to consist in the possession of a distant land: and to the attainment of this object, which was to give their value to all the rest, they sacrificed the flower of successive generations, and the strength and ornament of their respective countries. Yet with all these pernicious effects, the philosopher will find in the crusades, if not the origin, at least the chief auxiliary cause of a total change in the aspect of society; for though the tide of civilization, in which a return from its lowest depression was scarcely perceptible, might of itself have continued to rise, its motion would have been slow and feeble, but for an impulse undesignedly communicated by these extraordinary expeditions. We shall therefore subjoin a few remarks on the measure in which they affected, 1st, the political condition; 2d, the manners and customs; 3d, the literature and the arts; and 4th, the religion of Europe.

Effects of the crusades on the political condition of Europe.

1. The period at which the crusades began, was that at which the irruptions of the northern and eastern barbarians closed. These had confirmed their settlement in the countries which they overran, and had effaced every vestige of the Roman policy, by the introduction of their own. The latter, as might be expected, was rude and irregular, and from its military origin, terminated in what is too well known to require description by the name of the *Feudal System*. Under this system, the nobility enjoyed a subordinate sovereignty, in their own domains; and though acknowledging a species of allegiance to the king, as the original granter of their lands, yet the acknowledgment was understood to imply so imperfect an obedience, that its occasional violation was accounted neither criminal nor infamous. A kingdom resembled a cluster of confederated states, under a common head, like those of Greece in the days of Homer, with this difference, that, in the former case, the crown was hereditary, which rendered its power proportionally greater. When obedience was refused, it could be enforced only by war, and not by law; and thus a great baron was more like the royal rival than the subject of his nominal superior. He had his own courts of justice, his own mint, and his own army. He made war upon his neighbours; and the pillage of their domains was regarded as the spoils of conquest, not of robbery. Every kingdom was, therefore, a scene of turbulence and distraction; and the tenants of adjoining baronies felt the same mutual hostility, as the subjects of conterminous states at present. The king naturally strove to augment his authority, but he could do so only by dividing the nobility, and then securing the alliance of the most powerful, or by extending his own domains, in the way of purchase or forfeiture. Kings, therefore, encouraged the crusades, from secular, as well as from spiritual motives. The barons who engaged in them, acting not more from superstition, than from a desire of military glory, were generally the most warlike of this intractable order, and their absence was on that account desirable. Sums were required to convey their troops to foreign service, for which their annual revenues were insufficient; and as the expedient of loans was not yet devised, they were obliged to alienate their lands for such a price as they could obtain. Of this necessity their sovereigns took advantage, and by thus enlarging their personal possessions, enlarged their political power. When the kings themselves were infected by the crusading *mania*, they raised money from the sale of municipal privileges to the towns; and this, though an apparent abridgment, was a real extension of their authority. As the consequence of the people advanced, that of the nobility, which was injurious to order, and which opposed the chief resistance to royal authority, declined in proportion; and when this unintended effect was perceived, kings became more willing to emancipate the lower orders of their subjects from feudal servitude. In this manner corporations were formed, with a species of republican jurisdiction, within their own limits and ideas of liberty, which had long been dormant, began once more to revive. These made the most rapid progress, and reached the greatest perfection, in the maritime cities of Italy, which, from the wealth acquired, by supplying the means of transport and subsistence to the crusaders, were enabled to erect themselves into independent commonwealths. From the co-operation of all these circumstances, the power of government and the efficiency of law were increased; the protection thus afforded to property gave new confidence and a new motive to industry; and men being called into situations which obliged them to think and act for themselves, their faculties were quickened by exercise, and directed to objects of enquiry which had formerly been unknown. If, for example, we turn to England, in the reign of Edward the First, who had himself engaged in the last crusade, we find the power of the monarchy wielded with unprecedented ease and energy; we find the people embarking in commerce and navigation; we find the laws improved, and their administration invigorated; we find the rudiments of our present constitution distinctly visible; and we find the youth, instead of limiting their attention to bodily exercises, frequenting the universities, and cultivating their understandings. In France, at the same period, the advance was still more considerable; and though in both countries, partly owing to the personal character of the sovereigns, it must be also ascribed in part to the causes which have been already assigned.

Effects of the crusades on the manners and customs of Europe.

2. In the age preceding the crusades, the manners and mode of life which prevailed through Europe, were gross and unpolished. This must naturally be the case, among the members of small societies, who live in habits of ferocious hostility with their neighbours, and of close and rude familiarity with each other. Into such societies every kingdom was divided. The precincts of each estate were a constant scene of that border warfare, which is the most brutalizing of any; and the conviviality of the baronial hall was, as constantly, the reward of the vassals, on their return from pillage. Their lord was obliged, in order to secure their attachment, to indulge them in intemperance, and in those coarse and turbulent pastimes which suited "the unyoked humour of their idleness." Himself and his relations, having few other associates, were frequently induced to mix in their revels, and a tincture of masculine semi-barbarism was thus diffused, even through the higher orders of society. The distinction between the practice of private war and that of indiscriminate robbery was so faint and equivocal, that heroes of the highway were held in little dishonour, and the right of plundering passengers, within a definite district, was sometimes annexed, by grant, to the possession of certain manors. That respect for the fair sex, which is at once a cause, and a consequence of polished manners, could, in these days, have little influence, as women were classed among other articles of property and plunder, and depredations on *moveables* of this description were frequently the origin of the baronial wars. Previous to the crusades, indeed, a partial remedy, or rather a feeble palliative, for the evils created by this dissolution of order, had arisen from the institution of chivalry. Some individuals, whose natural ideas of justice and humanity were superior to those of their age, determined to supply the deficiencies of law, which permitted injuries too painful for their sensibility to witness, and assuming the character of judges, in every case of oppression, enforced their decisions by their own personal prowess. The weaker sex, and those of the other, who, from profession, were most pacific, became the principal objects of their protection; and the pleasing consciousness of performing acts of generosity, and at the same time of indulging the prevailing propensity to acts of valour, rendered the occupation fashionable, and introduced sentiments and manners of a new and interesting kind. These voluntary champions of injured innocence formed themselves into fra-

Effects of the crusades on the manners and customs of Europe.

ternities, which were governed by their own rules, and into which candidates were admitted with martial and religious ceremonies. In the modern orders of knighthood, these fraternities still preserve a nominal existence; but until chivalry was rendered superfluous by improvements in policy, and ludicrous by the humour of Cervantes, it continued to be a dignified and serviceable institution. For the encouragement and extension of these societies, nothing could be better adapted than the crusades, which were indeed a general enterprise, on the principles of chivalry, undertaken by confederated Christendom. The motive which led to them was indignation at the oppression exercised by the Saracens; and in their progress, many who engaged in them were reduced to such extremities of distress, and dereliction, that various orders of knighthood, especially those of St John and of the Temple, were founded expressly for their relief. The admiration which the crusaders enjoyed, rendered those eastern orders more honourable and permanent than others, and the spirit of chivalry was strengthened at home, by its adoption among the venerated warriors in Palestine. In this spirit were implied a punctilious obedience to the laws of honour, morality, and religion, a dignified courtesy of deportment, and an elaborate tenderness and respect for the fair. In short, *parcere subjectis et debellare superbos* was the general motive by which, on all occasions, it was to be swayed. The new direction which was thus communicated to the activity of human nature, and the ambition of extracting and combining all that is most laudable in the ecclesiastical and military characters, soon produced a visible effect on the aspect of society. Men became more guarded in their mutual intercourse; fashion succeeded, where better principles had failed in improving their conduct; and weakness being invested with an ideal sanctity, which gave it all the advantages of strength, the general comfort was increased by a consciousness of increased security. This direct and imperative operation of chivalry was essentially aided by the change of habits and opinions, which gradually and insensibly proceeds from foreign travel, and from the union of various nations in a common enterprise. Nothing is better fitted to supply the absence of literary education, than visiting new countries, and acting with new associates. It enlarges the views, and corrects false habits of thinking; it teaches us to regard in a proper light, things to which we had attached undue importance; it imposes the necessity of accommodating ourselves to practices and opinions at variance with our own; and it accustoms the temper to forbearance and pliability, and the mind to discretion and address in the ordinary affairs of life. Travelling of any description produces these effects, but travelling as a soldier accelerates them: for as the character is generally barbarised by the petty and acrimonious contests of neighbouring tribes, it is raised and refined, in an equal proportion, by military service on an extended scale, and against a remote and unhabitual opponent. We there contend with men to whom we are individually unknown, and against whom we feel no personal resentment; we learn to measure our hostility, not by passion, but by the necessity of the case; we learn from our own wants, to put the proper value on humanity, to mingle courtesy with valour, and to sympathise in the sufferings of the foe whom we have overcome. With our fellow soldiers, too, our companions in peril and privation, and in all the most interesting situations of life; the sharers in our wistful yearnings after that native land, which is endeared to us by a consciousness of extending its glory, and earning its applause, and to which, amid our toils, we often jointly look forward, sustained by the cheering hope of *fortasse et hæc olim meminisse juvabit*; with these we form a friendship of the most cordial and delicate kind, which exalts, as much as it softens the affections, and which, by giving exercise to the best dispositions of our nature, imparts a manly but captivating amenity to our general deportment.

Such were the effects to be expected from the expeditions to the East, and we accordingly find that, after their operation had time to be felt, the manners of the European nations underwent a perceptible change; while the general imitation of their darling champions introduced the rudiments of modern urbanity, and of those usages which, by implying mutual good will and respect, are found so convenient in smoothing the surface of social intercourse. In the East too, and especially in Constantinople, where the luxury and splendour of an imperial capital had never been interrupted by the establishment of barbarians, the crusaders became acquainted with modes of life which were superior to those of their own countries, and of which, on their return, they were ready to report the advantages, and urge the adoption. This produced, in the 12th and 13th centuries, a rapid improvement in the dignity of courts, in the refinement of pleasures, and in a general taste for those accommodations, and that order and elegance of domestic arrangements, with which the feudal nobility had never thought of gracing the rough hospitality of their halls. The castle of Windsor, which was built about 40 years after the termination of the crusades, is an existing monument of the sort of lodging which was then required by a monarch.

Effects of the crusades on literature and the arts.

3. At the time when the crusades began, Europe was involved in the grossest ignorance. All that remained of ancient science and art was confined to Constantinople, and to the more enlightened of the Saracens, who first from the vicinity, and afterwards by the conquest of Alexandria, added to their native literature a considerable knowledge of the Greek philosophy. Though, in visiting these regions, the crusaders were actuated by no desire of mental improvement, and could not boast even that portion of knowledge, which stimulates to the acquisition of more, yet they must, from the very boldness of the enterprise, have carried with them a vigour of mind, which is seldom unaccompanied by curiosity. This curiosity would be sharpened by an endless succession of new objects and singular characters; and it is scarcely possible that some of them should not have perceived the value of that information of which they were destitute. Of the clergy, in particular, who monopolized all the learning of the age, some among the numbers who proceeded to the East, might have been expected to study the language of the Greeks at Constantinople, or the philosophy of the Saracens in Egypt. No instances, however, can be given of the importation into Europe of any interesting addition to literature, by the votaries of the cross, and we must, therefore, content ourselves with the general fact, that the close of these expeditions was the commencement of a new era in the history of human intellect. The 12th century was the period when it seemed to awaken from its torpor, and to resume its activity, which, though long ill directed, was useful in preparing it for more judicious exertions. A distinguished author (Mr Gibbon) has maintained, that the progress of literature in Europe was retarded, not accelerated,

Crusades. Effects of the crusades on literature and the arts.

by the crusades. But this opinion seems objectionable, for the following reasons, drawn from the nature, and confirmed by the history of the mind. Exercise of one kind disposes the mental faculties, not to indolence, but to exercise of another. Even among barbarians, it is the old warrior who becomes the bard or historian of his tribe. It is those who have themselves made extraordinary exertions, who are most anxious to know what exertions have been made by others. It was after the long wars between the Spartan and Athenian states, that the genius of the Greeks broke out with greatest lustre; and we shall find, that all the golden ages of literature, either immediately succeeded, or actually coincided with periods of excessive agitation, from foreign or intestine conflicts. By analogy, therefore, we may infer that the interesting novelty, and extensive commotion of the crusades, were better fitted to excite the faculties, and fire the imagination, both of those who performed, and of those who promoted them, than the petty contests and insipid routine of rustic sports, which alone, but for this diversion, would have interrupted the slothful uniformity of their European homes.

In the intellectual progress of nations, poets and fabulous historians are the first writers who appear; and whatever stimulates the fancy may be considered as favouring the creation, because it accelerates the commencement of an age of literature. In this view the crusades must have been highly beneficial. They familiarised the minds of Europeans with the splendid fictions—the *speciosa miracula rerum*—on which the genius of the East has always delighted to dwell. Nay, the very occurrences of these expeditions, magnified by the vanity of those who had shared in them, were singularly suited to quicken the embryo seeds of poetry in the breasts of their ingenious countrymen. We accordingly find in the earliest writers of Europe, in Dante and Boccaccio, and in our own poets, from Chaucer to Milton, a frequent propensity to avail themselves of Oriental notions, and to give additional attraction to their writings, by allusions to the romantic adventures of the holy warriors, and to the preternatural, but interesting extravagances which were grafted on them. In so far, therefore, as the crusades supplied a spur to curiosity, and materials to those who could increase its impulse by gratification, in the same degree they must have contributed to assist the ordinary march of intellect, and to give it a more vigorous motion at its outset, than it would otherwise have so speedily acquired. Whatever hastens the age of poetry, must hasten that of philosophy, by which it is naturally succeeded. In addition to these speculative grounds of belief, we have direct evidence that the crusades, even by their successless issue, were of advantage to letters. The popes, after perceiving the inefficiency of carnal weapons, to resist the triumphs of Mohammedanism, had recourse to those of a spiritual and logical kind, by which they hoped, instead of conquering, to convert the Saracens. Young men were, therefore, appointed to be educated as future missionaries; and even at the early period of 1285, Pope Honorius had proposed the establishment of a college at Paris, for the purpose of instructing them in the Oriental languages, that, in his own words, "they might fulfil the intentions of his predecessors." Actuated by similar views, the council of Vienna, in 1311, declared that the revival of letters was the true method of converting the infidels, and of securing the recovery of the Holy Land; and we shall find, by inquiry, that it is nearly to the same period, and probably to the same design, the foundation of many foreign and domestic seminaries of learning must be referred.

On the other hand, it cannot be denied, that, if the crusades were ultimately useful, they were, in various respects, immediately detrimental to the advancement of knowledge. During their continuance, military fame was the chief object of ambition to all who aspired at distinction. A cultivated mind conferred no importance in society, compared with talents for war; and after the institution of chivalry, admission into any of its orders was sufficient to give a youth that rank and respect, the hope of which is the principal incentive to literary labour. Even when some would have preferred an attempt to advance themselves by the latter, they were prevented by the heavy contributions imposed for the equipment of crusading armies. These exhausted all their means, and obliged them to forego that education, and the provision of those books and other helps, for which studious men require a certain measure of ease, if not of affluence, in their circumstances. It must also be confessed, as a proof of the incurious ignorance of the age, that no part of Arabic science, of which Europe has availed itself, was imported by the crusaders. The arithmetical cyphers were known in the west, before the 11th century. The translation of Aristotle, whose authority continued to be long so unprofitably idolized, was obtained from the Saracens in Spain; and the astronomy and geography of the Arabs were transmitted to Christendom, through the same channel.

But if Europe was not much indebted to the crusades, for the direct improvement of science, with respect to the advancement of commerce and the arts, the case was very different. Before the 12th century, there had been no regular and systematic communication between the ports of Europe, and those of Asia and Africa. Commerce was so little valued, and so little understood, that France had allowed her maritime cities, on the Mediterranean, to remain in the hands of the counts of Tholouse, the kings of Majorca, and other petty princes; nor had the idea yet occurred to the Italians, of extending their traffic beyond their own vicinity, and of rendering their ports the *entrepots* for Indian commodities. In short, the numerous and signal advantages of water-transport had never drawn the attention of the European nations, till the destructive disasters of the first crusaders, in attempting a march by land, forced upon the mind of their followers the expediency of changing their element. Ships for their conveyance were, therefore, collected to an unusual number in the Mediterranean ports, and these were afterwards employed in carrying provisions to the crowd, which they had previously landed. By the consequent frequency of voyages to Palestine, the arts of navigation and shipbuilding were rapidly improved; and from this period may be dated the maritime eminence of Pisa, Genoa, and Venice. By the example of Italy, the French monarchs perceived the expediency of obtaining possession of the Mediterranean coast; but it was not till the embarkation of St Louis and his armies, which required no less than 1800 transports, that the port of Marseilles began to rise from its preceding obscurity. The impulse having once been given to the spirit of naval adventure, it went on with increasing activity, till it produced the remarkable change on the aspect of human affairs, which succeeded the discovery of America, and of the naval route to India. The profits, too, which arose from the supply of necessaries to armies at the distance of Palestine, called

Crusades.

the attention of traders to the advantages of an extended transfer of commodities; and the example of the Italian towns was gradually followed by other countries. Wealth was thus introduced into the states of Europe, and the inhabitants prepared, by the enjoyment of affluence and leisure, to relish and require the luxuries of knowledge and the elegant arts, which are never encouraged, till the more urgent cravings of nature have been supplied. In further proof of the benefit which trade derived from the crusades, we may add that the commercial regulations of Richard I. which he promulgated on his return from Palestine, under the title of the "Laws of Oleron," were the wisest then known, and no less remarkable for their justice and humanity than for their prudence.

Effects of the crusades upon religion.

4. To religion, as to letters, the crusades, though immediately injurious, were the remote cause of beneficial changes. At their commencement, the papal authority was in its plenitude, and the sovereign pontiffs, who had subjected Europe, were desirous of reducing Asia under their singular mixture of temporal and spiritual tyranny. But of all such attempts of extravagant ambition, the failure weakens, as the success confirms, the power of the projector. When Europe, disgusted by two centuries of disaster, began to suspect the folly of these expeditions, it must have also begun to doubt the infallible judgment of their ghostly promoters. This doubt, being once introduced into thinking minds, (and such must have been the first to entertain it,) would naturally increase; and when aided by the new vigour which reason had, from other causes, acquired, may be supposed to have operated, as a slow and imperceptible preparative for the doctrines of the reformation, the rudiments of which were suggested by Valdo, about 50 years before, and by Wickliffe, about 50 years after the final recapture of Palestine. During the progress of the crusades, however, that blind and fanatical devotion to the will of the priesthood, without which the people could never have been seduced into so wild an enterprise, seems to have rather increased than declined. Nothing, indeed, was omitted by the popes and their subordinate agents, to carry this principle to its most extravagant height, and thus to accomplish the object on which they had fixed, as necessary to the consummation of their paramount supremacy.

Indulgences, or an exemption from the penalties of purgatory, were granted with a profusion, most subversive of morality, to all who were willing, either by personal service or pecuniary contributions, to forward the conquest of Palestine. The eagerness of the people to drug their consciences, which were purposely agonized, by the venders of the opiate, rendered this artful expedient too productive to be discontinued, after the principal cause of resorting to it had ceased; and the sale of indulgences was afterwards converted into a regular branch of the ecclesiastical revenue. The infamy of such a traffic, in which the interests of virtue were sacrificed by those who exclusively pretended to maintain them, could not fail to be at length perceived, and is well known to have been the chief of those multiplied abuses of human ignorance, which gradually led intelligent men to detect the delusions, and to deny the legitimacy of the Romish church. During the crusades, the interests of the priesthood were artfully identified with those of the Christian faith; and the zealous, but bewildered, laity endeavoured to support the latter, by the most extravagant donations to the former. This liberality was generally directed to the monasteries; for the conventual character had acquired additional value with the people, from what they had seen or heard of the ascetic practices of the East. New monasteries were, therefore, endowed, and new fraternities instituted by the church, that it might provide sufficient channels, through which the bounty of its infatuated votaries should flow. But the popes, not contented with increasing the wealth and numbers of the priesthood, took advantage of the opportunity offered by the crusades to fortify themselves still farther, by instituting orders of knighthood, who, among their other duties, obliged themselves to be champions of the church and of all its rights. But even these auxiliaries, though an apparent addition of strength, in reality increased the weakness, and accelerated the downfall of pontifical domination. The ecclesiastical warriors, who, by a vow of celibacy, exposed themselves to double temptation, and who, under the sanctity of a semi-canonical vocation, could indulge with more freedom the licentiousness of military habits, speedily sunk into the most abominable debauchery. Wealth and indolence, too, produced their usual effects on the monastic orders, who shewed, by their open and unguarded indecencies, that they considered the subjection of the popular mind to be complete and irretrievable, and that the trouble of disguising their vices might therefore be spared. This security created in the popes such a contempt for the public understanding, as led them to insult it with the most absurd additions to the creed. Of this description were the doctrines of transubstantiation, the adoration of the host, the worship of the Virgin, and the efficacy of the rosary, all of which were the inventions of the 13th century. Though, for a time, these ludicrous or idolatrous tenets met with implicit belief, yet human reason, which, by its progressive maturation, was silently resisting every effort to protract its weakness, could not long submit to the wanton mockery which they implied. It was provoked to an investigation and assertion of its natural rights, the result of which, combined with indignation at the dissolute example of the military and monastic orders, contributed to produce that memorable revolt against papal oppression, by which, two centuries after, Christendom was convulsed and purified.

These causes were aided by the persecuting spirit of the church, which, if not created, was confirmed by the crusades. We naturally indulge hatred, from a desire of self justification, against those whom we attack; and hence, during the eastern expeditions, aversion at infidels became the most prevailing sentiment in Europe. This sentiment was propagated by the clergy with so much success, that we find it give a tincture to the style of the times, in which the epithets of *miscreant*, *paynim*, or *recreant*, are the strongest expressions of vituperation and abhorrence which language could supply. When the mind has been enslaved to such a feeling, it is easily transferred from unbelievers to those of our own communion, who differ from us, by the nicest shade of opinion, in religious metaphysics, and experience has abundantly proved, that, in the last case, its asperity is embittered, by the constant irritation which vicinity occasions, and by a closer contact with the objects of detestation. It is, therefore, by no means surprising that the wars with the Saracens, should have introduced an excessive jealousy of heretical notions, and an implacable spirit of persecution at home; or that the cruelties, which were the consequence, should, by natural reaction, have led to that obstinate resist-

Crusades.

Effects of the crusades upon religion.

ance, on the part of the sufferers, and to that exertion and illumination of mind, which terminated in the Protestant reformation.

We conclude with repeating, that the favourable results which we have attempted to trace to the crusades, even should the fairness of the deduction be admitted, will by no means exculpate their authors from the charge of criminal ambition, or enthusiastic folly. In manners, policy, and commerce, they had neither wisdom to foresee, nor virtue to design any improvement: and if their conduct produced advantages to literature and religion, these being diametrically opposite to their desires, implied as much demerit of intention, as the injudicious violence against a victim under torture, which exasperates a sullen tumour into an open ulcer, and thus accelerates the cure of an evil which it was expected to increase. See Gibbon's *History; Histoire Generale de* Voltaire; *Histoire des Croisades de Mainbourg; Esprit des Croisades.* (J. W.)

CRUSTACEOLOGY.

Crustaceology.

Crustaceology treats of the characters of two classes in Zoology, viz. Crustacea and Arachnides. Formerly, both these were arranged by Linné and his followers under the general denomination Insects, (*Insecta*); but the more extended, and consequently more accurate, observations of modern zoologists, have authorised the separation of the Crustacea and Arachnides from Insecta; a division perfectly warranted, not only by the difference of most important characters, but also the great facilities which it affords the student of nature. In the following pages, we shall first treat of the Crustacea, and then take into consideration the characters of the class Arachnides, which holds an intermediate place in the system of nature between the Crustacea and Insecta, and point out their systematic connection and arrangements.

Class I. CRUSTACEA.

Crustacea.

History.

This name, by which the class is distinguished, derives its origin from *crusta*, a *crust* or *shell*, because the animals have all a covering of that kind. The animals themselves are known under the familiar appellations of *crabs, lobsters, shrimps, prawns, centipedes, millepeds, &c* These were considered by the ancients as a subclass of fishes, connecting true fish with the testaceous vermes (*mollusca*); and this opinion prevailed, with very little variation, as recently as the time of Linné, who, in the great revolution which he effected in every part of natural history, separated the Crustacea from fishes and worms, and placed them with insects. After Linné, our industrious countryman Pennant seems to have been the first to separate the crustacea from insects. He has, however, neglected to assign any reason for this change, which renders it rather an innovation than a reform, and deprives him of any claim of priority which he might otherwise have deserved. He appears to have been rather influenced by caprice, than by any conviction of the correctness of his principles, (as we infer, from his wantonly re-connecting the whales with fishes, and in other instances, in which his chief aim appears to have been, to differ from his immortal predecessor Linné,) and on these grounds we shall not farther insist on his claims.

The illustrious French zoologists Cuvier, Lamarck, Latreille, and Dumeril, separated the *Crustacea* from *Insecta*, abandoning all the former opinions prevalent on the subject. How far they may have been right in thus rejecting the doctrines sanctioned by so many men of eminence, remains to be examined; and we are much disposed to think, that the grounds on which they have acted, will be found sufficiently firm to warrant the steps they have taken. In such enquiries, we are not to be governed by prejudice or veneration for the works of older writers, in those points where our own judgment may be employed with equal or even greater certainty. The *magni nominis umbra* has something so imposing on the minds of those too strongly inclined to worship it, that it cannot be too sedulously guarded against. Much caution is however, necessary, in the examination of innovations, and the utmost impartiality is to be used. It is true, that animals may have a decided resemblance in their external characters, whilst their internal structure is totally different. This has been considered the case with the classes in question, although it appears to us very absurd to have placed together animals so very distinct: How ridiculous must it appear even to the most cursory observer, to be told that crabs and lobsters are insects! yet such was the opinion of Linné, and even at this time (although the continental writers unanimously agree in considering them distinct) many collectors, either from accustomed habit, or veneration for Linné, still consider the crustacea as a branch of Entomology, and as they both agree in having articulated limbs and antennæ, they are admitted by most British collectors into their cabinets as genuine *insects*; their internal structure, economy, and external appearance, being disregarded.

We shall now lay before our readers, the observations of Cuvier, Dumeril, Latreille, and Lamarck, and endeavour to point out the most obvious distinctive characters of the Crustacea. It appears, that they agree with insects, in having in common with them articulated limbs and antennæ, but differ most essentially in anatomical structure. The Crustacea breathe by *gills* like the Mollusca, and have generally four *antennæ* or *horns*, and often six *mandibules* or *jaws*; likewise a *heart* like the Mollusca. They undergo little or no transformation; and lastly, they breed more than once. Insecta, on the contrary, breathe by *tracheæ* or *windpipes*, have never more than two *antennæ*, no *mandibules*, no heart, and they all undergo more or less transformation, and perish as soon as the procreation of their species is effected.

Such are the most remarkable characters of the two classes, which warrant, upon every principle, their separation from each other. Indeed Linné himself, with that clearness and accuracy which distinguished his general views in every department of natural history, has laid the foundations of these recent changes effected by the foreign zoologists. That great man has taught us to consider the internal organization "a natural, certain, and unerring guide in the classification of animals." We feel, therefore, fully convinced, that these changes will meet the views of all those who are competent to appreciate the true principles that should regulate every philosophical arrangement.

In the arrangement of the three classes Crustacea, Arachnides, and Insecta, we have adopted certain alterations suggested by Mr Leach, of which we shall give some account: He has proposed to take from the class Arachnides, the orders, I. Tetracera, II. Myriapoda of Latreille, and add them to the Crustacea; and also to take from the same class, the order Parasita of the same author, and add it to Insecta, which, by this alteration, will include all those animals having two antennæ and six legs: the Arachnides, by the same improvement, will take in all that have no antennæ; and, lastly, the Crustacea will comprehend the remainder. On this mode of arrangement we shall say nothing, except that it seems well adapted to facilitate the progress of the student, and on this ground appears to deserve attention.

The following are the characters of the class Crustacea:

Anatomical Character.

Heart single; branchiæ for respiration; no vertebræ; spinal marrow with many knots or ganglia; muscles for moving the feet.

External Character.

Body with naked jointed feet, formed either for swimming or running; no wings; covering crustaceous, horny, or membranaceous, either shield-shaped, or bivalve. Branchiæ placed under the shell.

This class is divided into three orders. 1. Entomostraca. 2. Malacostraca; and, 3. Myriapoda. The latter was placed in the class Arachnides, by Latreille; but, as already mentioned, we are inclined to place it with the Crustacea, for several reasons which we shall state in their proper place. We now proceed to define the Orders, Tribes, Families, and Genera of the class Crustacea.

ORDER I. ENTOMOSTRACA.

Feet either branchial, or furnished with leaf-like processes. Body, with a coriaceous or membranaceous covering, which is either shield-shaped or bivalve. Eyes, generally sessile or fixed; in some few pedunculated, or placed on a footstalk. Palpi, double. Mandibules, obscure or wanting.

In this order the antennæ are sometimes wanting, in some they are very obscure, in others pencil-shaped, or branched. The *eyes* are generally two in number, in some distinct, in others united, so as to appear as one; the *mouth,* furnished either with jaws or a proboscis. The *mandibules* without palpi. *Maxillæ* or *jaws,* four or six. *Feet,* generally ten in number, formed for swimming. *Tail,* furnished with lamellæ or setæ, and sometimes with a sword-like process.

Observation. Some of the animals of this order undergo changes during their growth; these peculiarities will be noticed when the individual species are described.

TRIBE I. THECATA.

Shell, shield-shaped.

Family I. Xiphosura.

The clypeus or shield double, completely covering the body; the feet simple and unequal in size; tail sword-shaped; antennæ scarcely visible; mouth with mandibules.

Genus I. Limulus. Shell composed of two pieces; mandibules double-jointed; tail horny and sword-shaped.

Family II. Pneumonura.

The clypeus single; feet simple, and unequal in size; mouth with a rostrum; tail fibrous, or leaf-shaped.

Genus II. Caligus. No mandibules; tail with two filaments; the anterior feet terminated by a hook, the rest formed for swimming.

Genus III. Binoculus. No mandibules; tail with two lobes; the anterior pair of feet terminated by a nail, the second pair conic, the rest formed for swimming.

Family III. Phyllopoda.

The clypeus single; all the feet furnished with leaf-like fins; tail fibrous or filamentous.

Genus IV. Apus. Mouth with mandibules; tail with two setæ; the feet leaf-shaped.

TRIBE II. OSTRACODA.

Shell bivalve; Eyes most frequently confluent.

Family IV. Monophthalma.

Eyes confluent, or running together so as to appear but one.

* Two eyes.

Genus V. Lynceus. Head exserted; antennæ capillary.

** One eye.

Genus VI. Daphnia. Head exserted; antennæ branched.

Genus VII. Cypris. Head concealed; antennæ terminated by a brush.

Genus VIII. Cythere. Antennæ hairy; head concealed.

TRIBE III. GYMNOTA.

Shell without any covering.

Family V. Pseudopoda.

Head closely united to the thorax; feet obscure or obsolete.

Genus IX. Cyclops. One sessile eye implanted in the front of the thorax.

Family VI. Cephalota.

Head large, and evidently distinct from the thorax.

* Eyes sessile.

Genus X. Polyphemus. One eye; two branched feet extending horizontally.

Genus XI. Zöe. Two eyes; rostrum longer than the thorax, and perpendicularly placed.

** Eyes pedunculated.

Genus XII. Branchiopoda. Body filiform.

ORDER II. MALACOSTRACA.

Feet either formed for swimming or running, the tarsus being furnished with a horny tail. Body, with a calcareous covering; two moveable and pedunculated eyes, (in the third Family the eyes are fixed.) Antennæ in all the genera four, four double. Palpi attached to the mandibules.

Crustacea.

In this order the covering is always calcareous, and is generally shield-shaped. *Antennæ* always four in number; the interior pair often divided. *Eyes* generally pedunculated, or placed on a footstalk; in some they are immersed in a socket. *Mouth* armed with jaws. The *mandibules* two in number, bearing palpi. *Maxillæ* six in number, placed in a longitudinal line, one above the other. Four double *palpi* situated under the maxillæ. *Feet* ten, in some fourteen, formed for swimming or walking; the tarsus terminated by a horny nail. *Tail* simple, or armed either with lamellæ or styles.

Observation. The animals of this order undergo no transformation; they are for the most part produced from eggs. In the last Family, the females carry about their young, until they are large and strong enough to provide for themselves.

TRIBE I. BRACHYURI.

Tail shorter than the body, having no caudal fin.

Family VII. Cancerides.

Shell transverse, or heart-shaped in some; round or square in others. The longitudinal very rarely exceeding the transverse diameter. Antennæ inserted into excavation on the middle of the clypeus.

I. Anterior part of the shell rounded; posterior margin straight.

* Hinder feet formed for swimming, the last joint being much compressed.

Genus XIII. Podophthalmus. Peduncle of the eyes reaching the external anterior margins of the shell.

Genus XIV. Portunus. Peduncle of the eyes much shorter than the external anterior margins of the shell.

** Hinder feet, as well as all the rest, formed for running, the last joint being conic.

Genus XV. Dromia. Hinder feet placed on the back. Shell very convex.

Genus XVI. Calappa. Posterior angles of the shell arched, so as to receive the hinder feet when contracted. Hands crested.

Genus XVII. Hepatus. The second joint of the peduncle of the external double palpi triangular.

Genus XVIII. Cancer. The second joint of the peduncle of the external double palpi quadrangular.

II. Shell more or less square.

Genus XIX. Ocypode. Eyes with an elongated footstalk inserted into the middle of the anterior margin of the shell.

Genus XX. Grapsus. Eyes with a short peduncle inserted in the anterior angles of the shell. Interior antennæ concealed by the inflexed clypeus.

Genus XXI. Plagusia. Eyes with a short peduncle inserted at the anterior angles of the shell. Interior antennæ inserted into two little foveolæ on the upper part of the clypeus.

Genus XXII. Pinnotheres. Shell roundish-square. The internal footstalk of the exterior double palpi one-jointed.

Family VIII. Oxyrhynchi.

Shell somewhat oval or triangular. The longitudinal exceeding the transverse diameter. The anterior antennæ generally exserted.

I. All the tarsi conic.

Genus XXIII. Leucosia. Eyes and antennæ minute. The footstalks of the external double palpi equal.

Genus XXIV. Maja. Eyes distant from one another, and not small. The joints of the internal footstalk of the external double palpi with two broad joints. Hinder feet not spurious.

Genus XXV. Macropodia. Eyes distant from one another. External double palpi porrected. The second joint of the footstalk elongated. Hinder feet not spurious.

Genus XXVI. Lithodes. Eyes near each other at their base. Hinder feet minute and spurious.

Genus XXVII. Corystes. External antennæ porrected as long as the body. The second joint of the internal peduncle of the external double palpi lengthened, and gradually narrowing towards the apex.

Genus XXVIII. Mictyris. The first joint of the internal footstalk of the external palpi very large.

Genus XXIX. Doryppe. The four posterior feet placed on the back.

II. The posterior feet compressed.

* All the feet inserted in the same horizontal line.

Genus XXX. Orythia. The two posterior feet terminated with a swimming joint.

Genus XXXI. Matuta. All the feet, except the anterior pair, terminated by a swimming joint.

** The four posterior feet placed over the others.

Genus XXXII. Ranina. All the feet, except the anterior pair, formed for swimming.

TRIBE II. MACROURI.

Tail longer than the body; the apex furnished with moveable lamellæ, which are termed fins. Feet ten or fourteen.

Family IX. Pagurii.

The caudal, lamellæ, or fins, placed at a distance from the middle lamellæ, and not forming with it a fan-shaped fin.

1. Some of the feet formed for swimming, the last joint being compressed.

* Hands with one finger.

Genus XXXIII. Albunea. Posterior feet small and filiform. The three anterior pair compressed, and armed with a hook.

Genus XXXIV. Remipes. Arms shorter than the second pair of feet; the rest formed for swimming.

** Hands simple.

Genus XXXV. Hippa.

2. Hands with a finger and thumb. Feet not formed for swimming.

Genus XXXVI. Pagurus. Tail armed with hooked processes.

Family X. Palinurii.

The lateral lamellæ meeting the middle process, and forming with it a fan-shaped fin. Peduncle of the antennæ very long, armed at the apex with a jointed seta.

I. All the feet (arms included) terminated by a conic tarsus.

Genus XXXVII. Scyllarus. Exterior antennæ short and broad. Eyes distant.

Genus XXXVIII. Palinurus. Exterior antennæ very long and setaceous. Eyes placed on a common peduncle.

II. The two anterior feet, or arms, with a compound hand. Posterior feet spurious.

Genus XXXIX. Porcellana. Shell roundish-square.

Genus XL. Galathea. Shell oblong-oval.

Family XI. Astacini.

The lateral caudal lamellæ meeting the middle process, and forming with it a fan-shaped fin. The interior antennæ with a short peduncle, armed with jointed setæ.

I. Feet ten. Hands didactyle.

* Interior antennæ with two setæ.

A. Antennæ placed in the same horizontal line.

Genus XLI. Astacus. Six anterior feet compound.

Genus XLII. Thalasina. Four anterior feet compound.

Genus XLIII. Upogebia. Two anterior feet compound.

Genus XLIV. Callianassa. The four anterior feet compound; third pair monodactyle.

B. Exterior antennæ inserted below the interior ones, with a large squama at their base.

Genus XLV. Alphæus. The four anterior feet compound.

Genus XLVI. Penæus. The six anterior feet compound.

** Interior antennæ with three setæ.

Genus XLVII. Palæmon. The four anterior feet compound.

II. Hands monodactyle, or with a moveable hook.

Genus XLVIII. Crangon.

III. Feet more than ten. Hands simple.

Genus XLIX. Praunus.

Family XII. Squillarii.

Eyes pedunculated. The first joint in the body the largest.

Genus L. Squilla. Interior antennæ with three articulated setæ.

Genus LI. Mysis. Interior antennæ with two articulated setæ.

TRIBE III. GASTERURI.

Eyes sessile. The joint of the body which receives the head, of the same size with the rest.

Family XIII. Gnathonii.

Mandibules two, prominent. Antennæ nearly equal. Feet ten, all armed with a fixed nail. Tail with two moveable plates on each side, forming, with a middle process, a swimming tail.

Genus LII. Gnathia.

Family XIV. Gammarini.

Tail armed at its extremity with several styles. Feet fourteen. Tail not distinct from the body.

* Superior antennæ shorter than the peduncle of the inferior.

Genus LIII. Talitrus. Anterior pair of feet largest.

Genus LIV. Orchestia. Anterior pair of feet smallest.

** Inferior antennæ shortest.

Genus LV. Gammarus. The four anterior feet equal, furnished with a moveable nail. Superior antennæ with a seta on the third joint of the peduncle.

Genus LVI. Maera. Anterior feet with a moveable nail, the second pair with a compressed hand and moveable thumb.

Genus LVII. Melita. Anterior feet with a compressed hand furnished with a moveable thumb.

Genus LVIII. Leucothöe. Anterior pair of feet with a finger and thumb, the second pair with a moveable thumb.

Family XV. Corophionii.

Body elongated; tail with four bifid styles; feet fourteen, anterior pair with a moveable thumb. The under antennæ as long as the body, (feet-like.)

Genus LIX. Corophium.

Family XVI. Caprellini.

Body six-jointed; all the articulations except the second and third bearing feet. Two oars on each side, placed on the sides of the second and third joint.

Genus LX. Caprella. Body linear; oars globular.

Genus LXI. Cyamus. Body depressed; oars elongated.

Family XVII. Apseudii.

Body six-jointed; tail also six-jointed; the end armed with appendices. Feet fourteen; the anterior pair armed with a finger and thumb; second pair compressed and denticulated. Inferior antennæ bifurcated.

Genus LXII. Apseudes.

ORDER III. MYRIAPODA.

Body, with seven or more feet-bearing articulations. Antennæ, filiform, two or four in number. Palpi, single. Eyes, immoveable.

The animals which compose this order were placed in the class Arachnides, by Lamarck and Latreille; but, from the characters we have given in the introduction to this article, it is more correctly referable to Crustacea.

Observation. The animals of this order undergo no transformation; it has been stated, however, that some of the Scolopendrides increase the number of their feet during their growth: this Mr Leach denies, for, in his cabinet, most of the indigenous species may be seen, from the smallest size to the mature state, agreeing in all points with full grown specimens.

TRIBE I. TETRACERA.

Antennæ, four or two in number. Feet, fourteen. The anal segment of the body without feet, being sometimes armed either with lamellæ or styles.

Family XVIII. Asellides.

Antennæ generally very distinct, sometimes obscure; the internal or middle as long as the peduncle of the external ones. The last segment of the body generally largest.

I. The four antennæ very distinct.

* The foliaceous appendices of the tail very large, each one formed of a double scale; the two scales parallel and meeting together.

Genus LXIII. Asellus. Tail formed of one segment, with two bifid styles; the four antennæ setaceous, the outermost division being formed of a vast number of little joints.

Genus LXIV. Idotea. Tail formed of two or three segments, without styles; superior antennæ filiform, having four great divisions, the outermost composed of a great many smaller joints.

* * Foliaceous appendices of the tail formed of one or two processes, placed on a common peduncle situated on each side of the tail.

Crustacea.

A. Two processes on each side of the tail.

Genus LXV. Anthoura. Tail with two broad lamellæ on each side, and a middle process; antennæ short, the upper pair longest. Anterior pair of feet furnished with a moveable hook.

Genus LXVI. Cymothoa. Tail composed of many segments; the body not rolling into a ball; the feet armed with strong nails.

Genus LXVII. Sphæroma. Tail composed of two segments; body capable of rolling into a ball; the tarsal nail of a moderate size.

B. One process on each side of the tail.

Genus LXVIII. Nesæa. Peduncle of the superior antennæ large, and long; body six-jointed, the last joint largest.

Genus LXIX. Campecopea. Peduncle of the superior antennæ not large, but longer than the inferior; the process at the side of the tail long and curved.

II. The four antennæ obscure or wanting.

Genus LXX. Bopyrus.

Family XIX. Oniscides.

The internal antennæ very short and obscure.

Genus LXXI. Ligia. External antennæ terminated by an articulated seta.

Genus LXXII. Philoscia. External antennæ eight-jointed; the base naked; the first joints of the tail abruptly narrower than the last joints of the body.

Genus LXXIII. Oniscus. External antennæ with eight joints, inserted under the margin of the head.

Genus LXXIV. Porcellio. External antennæ with seven joints, inserted under the margin of the head; lateral styles of the tail conical and projecting.

Genus LXXV. Armadillo. External antennæ with seven joints, inserted in a fovea, in which the margin is elevated; lateral styles of the tail not projecting, terminated by a triangular joint; (body capable of rolling into a ball.)

TRIBE II. MILLEPEDA.

Feet above fourteen. Antennæ two. All the segments of the body, the anal, and head excepted, bearing feet.

Family XX. Julides.

The maxillæ adhering to the lip, or wanting. Palpi tuberculiform and obscure.

* Body crustaceous.

Genus LXXVI. Glomeris. Body elliptical, convex above, arched beneath; rolling itself into a ball when touched.

Genus LXXVII. Julus. Body oblong; eyes granular, and very distinct.

Genus LXXVIII. Polydesmus. Body long; eyes obscure.

** Body soft.

Genus LXXIX. Pollyxenus. Body oblong, terminated by a pencil.

Family XXI. Scolopendrides.

Two very distinct maxillæ, connected at their base. Maxillary palpi two, which are filiform. Labial palpi also two in number, terminated by a little hook (hamulus.)

I. Each segment bearing two pair of feet.

Genus LXXX. Scutigera.

II. Each segment bearing one pair of feet.

A. Antennæ conico-setaceous.

* Feet forty-two.

Genus LXXXI. Scolopendra. Eyes eight.

Genus LXXXII. Cryptops. Eyes obscure.

** Feet thirty.

Genus LXXXIII. Lithobius. Eyes granular.

B. Antennæ filiform.

Genus LXXXIV. Geophilus.

ORDER I. ENTOMOSTRACA.

Entomostraca.

Family I. Xiphosura.

Genera and species.

1. Limulus.

Genus I. Limulus. Shell coriaceous, of a rounded oval form, rather narrower behind than before, notched and flattened. Clypeus double. Shell divided, the anterior division the largest, somewhat moon-shaped, with three elevated ridges on the back. Eyes two in number, small, oval, and obscure, placed on the under side of the carinæ or ridges. Back carinated, with a deep sulcus or groove on each side. Tail horny, attached to the body by a hinge-like joint. No antennæ. Two double jointed, cylindrical mandibules, situated on the under part of the anterior division of the shell; the outermost digitated, furnished with a finger and thumb, the former being moveable. Feet ten, all (excepting the anterior pair, which are most frequently simple,) furnished with a finger and thumb. The branchiæ, or gill-like lungs, situated under a horny lamella on the sides of the body.

Sp. 1. *Polyphemus.* All the feet digitated; tail three-sided, frequently somewhat notched above; the middle carina of the anterior scutum spiny. Polyphemus.

Inhabits the ocean of South America, where it is well known to sailors under the name of *king-crab.*

Monoculus polyphemus of Linné.

Limulus cyclops of Fabricius.

Sp. 2. *Moluccanus.* All the feet digitated; tail three-sided, notched above from the base to the apex. The middle carina of the scutum without spines. Moluccanus.

A native of the East Indian ocean. Latreille, Gen. *Crust. et Ins.* tom. i. p. 11.—*Molucca crab.*

Sp. 3. *Heterodactylus.* The four anterior feet simple. Inhabits China. Heterodactylus.

Limule hétérodactyle. Lat. *Hist. Nat. des Crust. et des Insect.* tom. iv. p. 89.

Limulus heterodactylus of Latreille's *Genera Crust. et Ins.*

Sp. 4. *Virescens.* The anterior pair of feet simple. Inhabits the East Indian seas. Virescens.

Limulus polyphemus of Fabricius.

Observation. Limulus noctilucus, discovered by Captain Horsburgh, and described by James Macartney, Esq. in an ingenious paper on luminous animals, *Phil. Trans.* 1810, Plate xv. p. 292, evidently belongs to a distinct genus, at present unknown to us.

Family II. Pneumonura.

2. Caligus.

Genus II. Caligus. Shell heart-shaped. Two eyes placed at a distance from one another, on the anterior margin of the shell. Antennæ minute, setaceous. Mouth with a conic rostrum, which is bent downwards. Feet either eight or ten; two or four of which are furnished with an inflexed nail, and are formed for walking; the pair following these walking feet are armed with setæ, (sometimes with a double nail,) the rest bearing leaf-like lamellæ. Abdomen exserted, and nar-

Crustacea. rower than the shell, the apex armed with two round filaments.

Piscinus. *Sp.* 1. *Piscinus.* Body short; tail bifid, with one leaf-like process.

A very common species, attaching itself to various fish, especially the holibut (*pleuronectes hippoglossus*).

Caligus curtus of Müller. *Monoculus piscinus* of Fabricius and Linné. *Binoculus piscinus* of Otho Fabricius.

Oniscus lutosus of Slabber.

Productus. *Sp.* 2. *Productus.* Body elongated; tail with three laminæ.

Found on the same fish with the preceding; common on the cod.

Monoculus salmoneus of Fabricius. *Caligus productus* of Müller.

3. Argulus. Genus III. Argulus. Shell oval, plain, and membranaceous; in front with two contractions, notched behind. Eyes two, placed at a distance from one another, on the sides of the anterior edge. Antennæ two, in some four, of a very small size, composed of three joints, conic at their base, but gradually tapering towards the apex, inserted between the eyes. Mouth with a conic pectoral rostrum. Feet twelve; the anterior pair tubular, and somewhat hemispherical, by means of which the animal attaches itself to any body; the second pair conic, composed of four joints, notched at their base. The other four pair double jointed, and formed for swimming.

Argulus. *Sp.* 1. *Argulus.* Body greenish-grey.

Binocule du gastéroste, Geoffroy.

Argulus dephinus, Müller.

Monoculus argulus, Fabricius.

Monoculus gyrini, Cuvier.

Binoculus gasterostei, Latreille.

Argulus foliaceus of Jurine.

Inhabits fresh waters, adhering to tadpoles and fish of various kinds, as carp, tench, &c.

Observation. A most scientific paper on this species, *Argulus foliaceus,* is given by young Jurine in the *Annales du Muséum d'Histoire Naturelle* for 1806, in which he accurately describes its anatomical structure and economy. *Argulus charon* of Müller is merely the young of *Argulus foliaceus,* as has been shewn by young Jurine in the above mentioned paper.

Family III. Phyllopoda.

4. Apus. Genus IV. Apus. Body soft, covered either with a membranaceous or semi-crustaceous shell, of a roundish-oval shape, deeply notched behind. Two moon-shaped prominent eyes, placed very near each other, on the anterior part of the head. Antennæ hair-like and double jointed. Mandibules two, one on each side, nearly of a cylindrical shape, very short and hollow within, somewhat waved at the apex, and compressed; the extreme point notched. Four depressed, horny, transverse maxillæ, two on each side, placed under the mandibules. About sixty pair of lung-like feet. The tail elongate, somewhat conic, truncated at the end; composed of many very short and obscure joints.

Caneriformis. *Sp.* 1. *Caneriformis.* The dorsal carina blunt behind; no lamella between the caudal setæ.

Inhabits marshes and stagnant pools.

Limulus palustris, Müller.

Monoculus apus, Fabricius.

Apus cancriformis, Latreille.

Productus. *Sp.* 2. *Productus.* The dorsal carina spined behind; a lamella inserted between the caudal fins.

Found in the same situations as the preceding species. Is the *Monoculus apus* of Linné, well described by him in *Fauna Suecica,* ed. sec. p. 498. "*Cauda setis duabus validis, interjectâ lamellâ.*"

Family IV. Monophthalma.

5. Lynceus. Genus V. Lynceus. Eyes two. Antennæ two or four in number, setaceous or hair-shaped. Feet eight in number. Head exserted.

Brachyurus. *Sp.* 1. *Brachyurus.* Antennæ four; shell globose; tail deflexed.

Inhabits ponds and marshes.

Monoculus brachyurus of Fabricius.

Lynceus brachyurus of Latreille.

Sphæricus. *Sp.* 2. *Sphæricus.* Antennæ two; shell globose; tail deflected.

Inhabits ponds and marshes.

Monoculus sphericus of Fabricius.

Lynceus sphericus of Latreille.

6. Daphnia. Genus VI. Daphnia. Müller, Latreille. Eye one. Head exserted. Antennæ two, branched. Feet eight. (or twelve).

Pulex. *Sp.* 1. *Pulex.* Tail inflected; shell pointed behind.

Daphnia pennata of Müller.

Monoculus pulex of Linné and Fabricius.

Daphnia pulex of Latreille.

Pulex caudatus of Schæffer.

Inhabits Europe.

7. Cypris. Genus VII. Cypris. Muller, Latreille. Eye one. Head concealed under the shell. Antennæ setaceous, branched, and inserted above.

Conchacea. *Sp.* 1. *Conchacea.* Shell oval, transparent, and hairy.

Monoculus conchaceus, Linné and Fabricius.

Cypris pubera, Müller.

Cypris conchaceus, Latreille.

Inhabits fresh waters.

Detecta. *Sp.* 2. *Detecta.* Shell somewhat kidney-shaped, and transparent.

Cypris detecta, Müller.

Inhabits Europe.

Reniformis. *Sp.* 3. *Reniformis.* Shell kidney-shaped and green.

Cypris reniformis, Dardebart de Férussac, fils.

Inhabits France and Britain. First described by the son of Dardebart dé Ferussac, in the *Annales du Muséum d'Histoire Naturelle* for 1806. It has been taken in Duddingston Loch, near Edinburgh, and in various ponds in Devon, by Mr Leach. See Plate CCXXI, Fig. 2. Plate CCXXI. Fig. 2.

8. Cythere. Genus VIII. Cythere. One eye. Head concealed. Antennæ two, inserted above, and hairy.

Viridis. *Sp.* 1. *Viridis.* The shell green, kidney-shaped, and tomentose.

Cythere viridis, Mül. *Ent.* p. 64. tab. 7. fig. 1, 2; Latreille, *Gen. Crust. et Ins.* tom. 1. p. 19.

Cythérée verte, Latreille, *Hist. Nat. des Crust. et des Ins.* tom. iv. p. 252.

Monoculus viridis, Fab. *Ent. Syst.* tom. ii. p. 494.

Inhabits fuci and marine confervæ of the north of Europe.

Family V. Pseudopoda.

9. Cyclops. Genus IX. Cyclops. Müller, Latreille. Eye one. Body elongate, ovate-conical form. Antennæ two or four. Feet six or ten.

Quadricornis. *Sp.* 1. *Quadricornis.* Antennæ four; tail straight and bifid.

Monoculus quadricornis of Linné, Fabricius, Donovan.

Cyclops quadricornis of Müller and Latreille.

Inhabits ditches and gently running streams of water.

Amymones nauplii of Müller, is merely the young of this species, or of some other.

Longicornis.

Sp. 2. *Longicornis.* Two very long antennæ; tail bifid.

Monoculus longicornis, Fabricius.

Cyclops longicornis, Müller, Latreille.

Inhabits the Norwegian Sea.

Observation. The above species are very distinct and well marked; but we are sorry to inform our readers that this is not the case with the others, all of which inhabit fresh waters, but are by no means distinctly defined. The species alluded to are *Cyclops rubens, cœruleus, claviger,* and *mulleri.* On the latter, a long and elaborate paper is given in the *Annales du Muséum d'Histoire Naturelle* for 1806, but we have heard from good authority, that it has been described under another name in the works of Müller. We shall therefore be silent on the subject, and pass it without further notice.

Family VI. Cephalota.

* Eyes sessile.

10. Polyphemus.

Genus X. Polyphemus. Head distinct from the thorax. One eye. Thorax distinct from the abdomen, which is oval and crustaceous, compressed and crooked. Tail very much inflected. Two bifurcate processes extended horizontally. Eight short retuse feet, armed with setæ.

Oculus.

Species 1. *Oculus.* Body greenish-grey, oars blackish.

Inhabits marshes and lakes. Besides this, Mr Leach believes there are many other species which have been confounded with it: It is *Polyphemus oculus* of Müller and Latreille, *Monoculus pediculus* of Fabricius, *Cephaloculus stagnorum* of Lamarck.

11. Zöe.

Genus XI. Zöe. Head indistinct, with two large globose eyes. Rostrum nearly perpendicular, rather larger than the thorax, with the apex acute. Four antennæ inserted beneath the eyes; the interior simple, the exterior geniculated and bifid. Thorax somewhat oval. Back produced into a recurved spine twice as long as the thorax. Feet short, and hid under the thorax, with the exception of the hindermost pair, which are long, and formed for swimming. Tail, length of the thorax, and often inflected or bent up under it, composed of four joints; the first four very narrow, the last largest and lunated.

Pelagica.

Species 1. *Pelagica.* Colour cinereous.

Inhabits the sea every where.

Zöe pelagica, Bosc, *Hist. Nat. des Crust.* tom. ii. p. 135. *Monoculus taurus* of Slabber.

** Eyes with a distinct peduncle.

12. Branchiopoda.

Genus XII. Branchiopoda. Body filiform, and very soft. Head divided from the thorax by a very narrow but distinct neck. Two lateral moveable eyes. Two short, double-jointed, capillary antennæ, inserted behind and above the eyes. Front armed with two moveable tentaculæ or horns, (broader towards the apex in the male,) which are notched: those of the female jointed, and bearing a papilla on their point. In the front of the male, at the base of the tentaculæ, are two long hair-like filaments; the clypeus in this sex is double. In both sexes, the mouth has a hooked rostriform papilla, supported by four little processes. The trunk of the body keel-shaped, consisting of eleven joints, each bearing two branchial feet; the anterior pair with two, the posterior with three lamellæ. The tail about the length of the body, composed of six? or nine? obscure joints; the anal segment bearing two fins. The organs of generation situated at the base of the tail.

Stagnalis.

Species 1. *Stagnalis.* Body transparent, of a light-brown colour, slightly tinged with green or blue, particularly on the head and legs.

Cancer stagnalis of Linné and Shaw, *Gammarus stagnalis* of Fabricius, *Branchiopoda stagnalis* of Lamarck and Latreille, *Apus piciformis* of Schæffer.

A most ingenious and accurate paper has been written on this species by Dr George Shaw, in the *Transactions of the Linnean Society of London,* vol. i. of which we shall here avail ourselves.

"It is generally found in such waters as are of a soft nature, and particularly in those shallows of rain-water which are so frequently seen in the spring and autumn, and in which the *Monoculus pulex* of Linné, and other small animals, abound. At first sight, it bears some resemblance to the larva of a dytiscus; but when viewed closely it is found to be of a much more curious and elegant appearance than that animal. The legs, of which there are several pair (eleven?) on each side, are flat and filmy, and have the appearance of so many waving fins, of the most delicate structure imaginable. The whole animal is extremely transparent, and the general colour is brown, slightly tinged with bluish-green. These creatures should seem, by their appearance, to be of a predaceous nature, the structure of their fangs seeming to be particularly adapted to the purpose of seizing their prey; yet (Dr Shaw observes) I never observed those which I kept to attack any of the animalcules which were in the same water; on the contrary, *Monoculus conchaceus* of Linné very frequently assaults them, and adheres with such force to their tails or legs, as sometimes to tear off a part in the struggle. It delights much in sunshine, during which it appears near the surface of the water, swimming on its back, and moving in various directions, by the successive undulations of its numerous fin-like legs, and moving its tail in the manner of a rudder. On the least disturbance, it starts in the manner of a small fish, and endeavours to secrete itself, by diving into the soft mud. It changes its skin at certain periods, as is evident, from the exuviæ or slough being frequently found in the water in which these animals are kept.

Linné, as appears in the last edition of the *Fauna Suecica,* had observed this animal, but, though he particularly mentions the appearance of the ovarium, he proposes a most extraordinary doubt, whether it may not prove to be the larva of some species of ephemera. He repeats this question in the *Systema Naturæ.*

"In March and April, the females deposit their eggs without any settled order, and perfectly loose in the water. They appear to the naked eye like very minute globules of a light brown colour. Each ovum, when magnified, closely resembles the farina of a mallow. It is thickly beset with spines on every side, and coated over with a transparent gelatinous substance, reaching just to the extremities of the spines, and is most probably intended to assist in causing them to adhere to the substances on which they may chance to fall, or as a security from the attacks of smaller insects. In about a fortnight or three weeks, the eggs are hatched, and the young animals may be seen to swim with great liveliness, by means of three very long pair of arms or rowers, which appear disproportionate to the size of the animal, and indeed it bears in this very small state not much resemblance to the form it afterwards assumes; but, in the short space of a very few hours, the body assumes a lengthened form, and begins to acquire the tail-fin. The eyes in this state do not appear pedunculated. On the seventh day after hatching, they approach pretty nearly the form of the perfect animal; they, however, still retain the two first pairs of rowers or arms. The legs are at this period very visible. About the ninth day it loses the long oars, and appears still more like the animal in its advanced state." Its growth is but slow, and it is highly probable that a very considerable time elapses before the insect acquires its full size; but this the Doctor tells us he cannot presume to determine, as those he kept died before they had acquired any considerable size. When first hatched, they are scarcely larger than the common mite.

Cancer paludosus of Müller (*Zool. Dan.* p. 10, tab. 48, fig. 1.) is a distinct species, if his figure be correct. It differs in its tentacula and tail. Latreille thinks it very probable that *Cancer salinus* of Linné, and *Cancer paludosus* of Otho Fabricius, may also belong to this genus.

ORDER II. MALACOSTRACA.

FAMILY VII. CANCERIDES.

MALACOSTRACA.

A. The last joint of the hinder feet flattened, and formed for swimming.

13. PODOPHTHALMUS.

GENUS XIII. PODOPHTHALMUS. The peduncle, or footstalk, on which the eyes are placed, as long as the external angles of the shell.

Vigil.

Sp. 1. *Vigil.* Anterior claws, and external anterior angle of the shell, spiny.

A native of the shores of India.

Podophthalmus spinosus, Lamarck; *Portunus vigil*, Fabricius. (*Suppl. Ent. Syst.* 365.)

14. PORTUNUS.

GENUS XIV. PORTUNUS. The peduncle of the eyes much shorter than the anterior angle of the shell.

* Shell with more than five teeth on each side; hinder spine very long. Gen. *Lupa*, Leach's MSS.

Pelagicus.

Sp. 1. *Pelagicus.* The shell on each side with nine teeth, the posterior tooth largest; hands on the front feet angulated; the front with four equal teeth; two teeth-like processes are on each side, at the internal angle of the eyes.

Inhabits the sea every where, attaching itself to the Fucus natans, or floating tangle.

It is *Portunus pelagicus* of Fabricius; *Cancer pelagicus* of Linné.

See *Lupa* in Index.

Lupa pelagica, Leach's MSS.

** Shell with five teeth on each side; transverse much greater than the longitudinal diameter.

a Orbit of the eye behind, with one fissure. Gen. *Carcinus*, Leach's MSS.

Mænas.

Sp. 2. *Mænas.* Shell smooth, with five teeth on each side; clypeus with three rounded teeth or lobes. When alive green, mottled with black; hands with one tooth; wrists with a spine.

Inhabits the rocky shores of the European ocean, lurking under stones and tangle. Vast numbers are sold in London to the poor, who esteem them as great delicacies. The young, or fry, are frequently mottled or bordered with white.

Cancer mænas of Linné, Fabricius, Latreille, Pennant, &c.

b Orbit of the eye behind, with two fissures. Gen. *Portunus*, Leach's MSS.

1. Hinder nails with an elevated rib; wrists with two teeth.

Puber.

Sp. 3. *Puber.* Shell covered with a velvet-like down, five equal teeth on each side; the front beautifully denticulated; hands striated, with one spine on the upper side; wrists with two teeth.

Inhabits the Mediterranean and British seas.

This is *Cancer puber* of Linné; *Portunus puber* of Fabricius and Latreille; *Cancer velutinus* of Pennant.

This species, when alive, is a most beautiful animal. The anterior claws are mottled with blue and black; the eyes likewise exhibit a rich scarlet colour striped with blue. It is by no means uncommon on the rocky coasts of Devonshire, being found at low tide under stones and fuci. It is probably the species taken notice of by Aristotle, on account of the broad feet, which he says assist them in swimming, as webbed feet do the water fowl.

2. Hinder nails, with an elevated rib; wrists with one tooth.

Corrugatus.

Sp. 4. *Corrugatus.* Shell with transverse serrate-granulated lines, ciliated with hair; front with three short teeth, middle one largest; sides with five nearly equal in size; wrists with a sharp tooth.

Cancer corrugatus of Pennant.

Mus. Montagu.

Emarginatus.

Sp. 5. *Emarginatus.* Shell convex, with abbreviated lines of granules; sides with five teeth, the fourth smallest; front notched; wrists with a strong tooth.

Portunus emarginatus, Leach's MSS.

Discovered at Torcross; we have seen the female only.

Mus. Leach.

Arcuatus.

Sp. 6. *Arcuatus.* Front arcuated, in other respects exactly like *Portunus emarginatus.*

Mus. Sowerby, Leach. The female has not occurred.

Mr Montagu considers this as the male of *Portunus emarginatus.* Mr Leach thinks that *Emarginatus* may prove to be an accidental variety of this species; but considers the distinctions as too strong for usual sexual distinction.

3. Hinder nails without an elevated rib; wrists with one tooth.

Depurator.

Sp. 7. *Depurator.* The clypeus and shell on each side, with five nearly equal teeth; the wrists internally with a sharp spine; shell with oblique granulated lines; front with three teeth, middle one rather longest; hands above with one spine.

Inhabits the European ocean. It is found on all the shores of Great Britain, inhabiting water of twenty fathoms. It is well known to the fishermen under the name of flying crab, and is supposed by them (though erroneously) to destroy oysters, by insinuating its flattened hinder foot into the shell, when the animal opens for food.

Portunus depurator of Fabricius; *Cancer depurator* of Linné.

Lividus.

Sp. 8. *Lividus.* The clypeus with three teeth, middle one rather longest; shell on each side with five nearly equal teeth; hands above with one tooth; wrists internally with a sharp spine; shell smooth, and more depressed than in *Depurator*.

A single specimen was taken by Mr Leach at Newhaven, since which time he has seen another in the collection of Mr Montagu. The eyes are smaller, and the antennæ are shorter, than in *Portunus depurator.*

Portunus lividus, Leach's MSS.

Marmoreus.

Sp. 9. *Marmoreus.* Shell convex and smooth, with very obsolete granulations; front with three equal teeth, sides with five; hands smooth; wrists with one sharp tooth within.

Cancer pinnatus marmoreus, Montagu's MSS.

Portunus marmoreus, Leach; *Malacost. Brit.*; *Portunus*, Tab. A.

The shell, when alive, most beautifully marbled with red and white. Discovered at Torcross in the southern coast of Devon, by G. Montagu, Esq. where it is not uncommon.

*** Shell with five teeth on each side; longitudinal equal, or nearly equal, to the transverse. Orbit of the eye entire. Gen. *Portumnus*, Leach's MSS.

Variegatus. *Sp* 10. *Variegatus*. Shell somewhat triangular, with five teeth on each side. Three teeth on the clypeus, and one over each eye. Last joint of the posterior feet somewhat lanceolated.

Inhabits the sandy shores of Great Britain, and is esteemed a rare species. When alive, is of a yellowish white colour, mottled with purplish brown.

See *Portumnus*. Index.

Portumnus latipes, Leach's MSS.

Cancer latipes of Pennant.

Cancer latipes variegatus, Plane.

B. Hinder feet, as well as the rest, formed for walking.

15. Dromia. Genus. XV. Dromia. Hinder feet placed on the hinder part of the back. Shell very convex.

Rumphii. *Sp*. 1. *Rumphii*. Shell hairy, with five acute teeth on each side. Arms and feet smooth.

Inhabits the East Indies, and is the only species of the genus known.

Cancer dromia of Linné; *Dromia rumphii*, Fabricius and Latreille.

16. Calappa. Genus XVI. Calappa. Hinder angles of the shell arched, receiving the feet when contracted. Hands crested.

Tuberculata. *Sp*. 1. *Tuberculata*. Shell warty; the posterior angle with six wrinkled teeth; the posterior angle with two obscure teeth or spines.

A native of New Holland.

Calappa tuberculata of Fabricius.

Fornicata. *Sp*. 2. *Fornicata*. Posterior angles of the shell rounded and smooth.

Inhabits New Holland.

Caner calappa of Linné; *Calappa fornicata*, Fabricius and Latreille.

Granulata. *Sp*. 3. *Granulata*. Shell tuberculated, with the posterior angles spined, the hindermost spines very sharp and large; posterior margin notched a little at the base of the tail.

Inhabits the shores of the Mediterranean Sea, and is found at low tides lurking under fuci.

Cancer granulatus of Linné; *Calappa granulata* of Fabricius and Latreille.

17. Hepatus. Genus XVII. Hepatus. The second joint of the footstalk, or peduncle of the external double palpi, triangular, becoming gradually narrower towards the apex.

Fasciatus. *Sp*. 1. *Fasciatus*. Shell banded with brown.

Inhabits America.

Calappa angustata of Fabricius; *Hepatus fasciatus* Latreille.

18. Cancer. Genus XVIII. Cancer. Shell narrow behind. The second joint of the footstalk of the external double palpi quadrangular, notched at the apex internally, for the insertion of the following joint.

* Arms of the male considerably longer than those of the female.

Pagurus. *Sp*. 1. *Pagurus*. Shell on each side, with nine folds; the apex of the hand black.

Cancer pagurus of Linné, Fabricius, Latreille, and Pennant.

The common crab of our markets, the *Crabe pagure* of French writers, is in season between Christmas and Easter, and about harvest, and is esteemed the most delicious species of the genus. Its natural history is but little known. During summer, it inhabits all our rocky coasts, generally preferring twenty fathoms water. In the winter, it is rarely met with, during which time it is said to burrow in the sand. The tips of the claws were formerly used in medicine, to correct acidities in the stomach: this absurd practice is now deservedly rejected

It is taken in wicker baskets resembling a mouse trap, or in nets with large meshes, which are sunk to the bottom, and baited with garbage.

Sp. 2. *Incisus*. Back wrinkled. Sides of the shell with four obtuse teeth. Fingers black. Colour when alive florid. Incisus.

Cancer florridus of Montagu.

Cancer incisus of Leach, MSS.

Inhabits the shores of Europe. In Great Britain it is considered extremely rare, having been taken only by Mr Montagu, and Mr Leach, on the rocky coasts of Devon at low tides, where it is common.

Not *C. florridus* of Linné, which is an unknown species, as the description in the *Amœnitates Academicæ* will evince.

Mus. Leach, Montagu, Sowerby.

** Arms of the males not evidently larger than those of the female.

Sp. 3. *Hirtellus*. Body and legs hairy; the shell with five dents on each side; claws somewhat muricated on the outside. Hirtellus.

Inhabits the European ocean. In England it is esteemed a great rarity, having only been found hitherto on the coasts of Devonshire.

Cancer hirtellus, Pennant. *Bristly crab*.

Mus. Donovan, Leach, Montagu.

Sp. 4 *Spinifrons*. Shell smooth, with teeth on each side; the second and third teeth bifid; the front and claws with many spines. Spinifrons.

Inhabits the European ocean.

Cancer spinifrons of Fabricius, *Sup. Ent. Syst*. p. 339; and of Latreille.

Sp. 5. *Denticulatus*. Shell tuberose, with the sides spiny; clypeus with five teeth, the middle one longest, the basilar ones shortest; arms angulated. Denticulatus.

Inhabits England and Scotland.

Described and named by George Montagu, Esq. in the *Transactions of the Linnean Society of London*, vol. ix. from a specimen sent him by Mr Boys of Sandwich. He mentions having seen a Scotch specimen in the collection of Edward Donovan, Esq. F. L. S. &c. Lately taken in Devon by Mr Prideaux, an assiduous naturalist.

Genus XIX. Ocypode. Eyes with an elongated footstalk, inserted into the middle of the anterior margin of the shell. Shell rhomboidal, or heart-shaped. 19. Ocypode.

See *Gecarcinus* in Index.

Sp. 1. *Uca*. Shell somewhat truncate-cordate, with the sides abruptly convex; feet hairy; the tarsi with five or six elevated lines, which are rather warty; hands tuberculated with tufts of hair both above and below. Uca.

Cancer uca of Linné; *Ocypode uca* of Latreille.

Inhabits South America. Latreille.

We strongly suspect this to be the species commonly known by the name of land crab, of which Sloane, Catesby, and others, have given such detailed accounts. The following, selected from such authorities, may probably not prove unacceptable. "These animals live not only in a kind of orderly society in their retreats in the mountains, but regularly march once a year down to the sea side, in a body of some millions at a time, as they multiply in great numbers. They choose the month of April or May to begin their expedition, and then sally out by thousands from the stumps of hollow trees, which they excavate, from the holes which they dig for themselves under the surface of the earth, clefts of the rocks, and other hiding places. At that time, the whole ground is covered with this band of adventurers; there is no setting down one's foot without treading on them.

"The sea is their place of destination, and to that they direct their march with the utmost precision. They never turn to the right or left for any obstacles that intervene, if they can possibly pass over them; and even if they meet with a house they will attempt to scale the walls. But though this be the general order of the route, they are upon other occasions obliged to conform to the face of the country; and if it is intersected with rivers, they are seen to wind along the course of the streams; but if only a small rivulet occurs, they force a passage across it. The procession sets forward from the mountains with the regularity of an army, under the guidance of an experienced commander. They are said to be commonly divided into three battalions, of which the first consists of the strongest and boldest males, that, like pioneers, march forward to clear the route and face the greatest dangers. They are often obliged to halt for want of rain, and to go into the most convenient encampment till the weather changes. The main body of the army is composed of females, which never leave the mountains till the rain is set in for some time, and then descend in regular order, being formed into columns of fifty paces broad, and three miles deep, and so close, that they almost cover the ground. Three or four days after this, the rear guard follows, a straggling undisciplined troop, consisting of males and females, but neither so robust nor so vigorous as the former. The night is the chief time of proceeding, but if it rains by day they do not fail to profit by the occasion; and they continue to move forward in a slow uniform manner. When the sun shines and is hot upon the surface of the ground, they halt and wait until the cool of the evening. When they are terrified, they march backward in a confused and disorderly manner, holding up their nippers. They try to intimidate their enemies by clattering their nippers together, as if it were to threaten those who come to disturb them. Their disposition is carnivorous, though they most commonly subsist on vegetables; for if, by any accident, one should get maimed in such a manner as to be incapable of proceeding, the rest fall on him and devour him on the spot, and then pursue their journey.

"After a march of sometimes two or perhaps three months, in this manner they arrive at their destined spot on the sea-coast, and then proceed to cast their spawn. The eggs are as yet within their bodies, and not excluded and retained, as is usual with animals of this kind, under the tail; for the creature waits for the benefit of the sea water to facilitate their exclusion. For this purpose, the crab has no sooner reached the shore, than it goes eagerly to the edge of the water, and lets the waves wash over its body two or three times. This has been thought necessary by some to ripen the spawn in the ovaria, as the crab appearing satisfied after a slight bathing, immediately retires, and seeks a lodging on the land. After this they say the spawn grows larger, is excluded from the body, and adheres to the ciliations under the tail. This bunch is seen as big as a hen's egg, and exactly resembling the roes of herrings. In this state of pregnancy they once more seek the shore for the last time; and shaking their spawn into the water, leave them to the chance of fortune and accident to bring them to maturity. At this time large shoals of hungry fishes are at the shore in expectation of this annual supply; the sea, to a great distance, seems quite black with them, and about two-thirds of the eggs are immediately devoured by those rapacious invaders. The eggs that escape are hatched under the sand, and soon after millions at a time of those little crabs are seen quitting the shore and slowly travelling up to the mountains. The old ones, however, are not so active to return; they have become so feeble and lean that they can hardly crawl along, and the flesh at the time changes colour. The greater part of them, therefore, are obliged to continue in the plains and lower parts of the country, until they recover, making holes in the earth which they cover with leaves and dirt, so as to exclude the light and air. In this cavity they throw off their old shells, which they leave behind them, as it were quite whole. At this time they are quite naked, and almost without motion for six days together, when they begin to grow fat, and are then most delicious eating. It is said they have under their stomachs four large white calcareous stones, which gradually decrease as in proportion the shell hardens, and when they come to perfection entirely disappear. Soon after this the animal is observed slowly making its way back, and all this is commonly performed in the space of six weeks. This animal, when possessed of its retreats in the mountains, is impregnable; for only subsisting on vegetables, it seldom ventures out; and its habitation being in the most inaccessible places, it remains for a greater part of the season in perfect security. It is only when impelled by the desire of bringing forth its young, and when compelled to descend into the flat country, that it is taken. At that time the natives wait for their descent in eager expectation of their arrival, and destroy thousands; but disregarding their bodies, they only seek for the small spawn which lies on each side of the stomach, within the shell, of about the thickness of a man's thumb. They are much more valuable on their return, after they have cast their shells; for being covered with a skin resembling soft parchment, almost every part except the stomach may be eaten. They are taken in the holes by feeling for them with an instrument; they are sought after by night, when on their journey, by flambeaux light. The instant the animal perceives itself attacked, it throws itself on its back, and with its claws pinches most dreadfully whatever it happens to fasten upon. But dextrous crab-catchers take them by their hinder legs in such a manner that they cannot make use of their nippers, and thus throw them into their bags. Sometimes also they are taken when they take refuge in the bottoms of holes in rocks on the sea-side, by clapping a stick to the mouth of the hole, which prevents their getting out; and then soon after the tide coming, enters the holes, and the animal is found, upon the water retiring, drowned in its retreat.

"These crabs are of various colours: some are reddish, variegated with black; some yellowish, and others black, inclining to blue. Those of a light colour are esteemed most, and when full in flesh are well tasted. In some of the sugar islands they are eaten without apprehension of danger, and form no inconsiderable part of the food of the poor negroes."

They vary much in size; the largest grow to about

Crustacea. six inches wide; they walk sidewise. They are said to be poisonous, and to have killed several people who have eaten them, particularly the black kind. The lighter coloured varieties are most esteemed, and are frequently fattened for the table.

Ruricola. *Sp.* 2. *Ruricola.* Shell of a somewhat truncated heart-shape; with the sides very abruptly convex; the tarsi with six serrated elevated lines; hands smooth.

Inhabits South America, and most probably has the same habits with the preceding species, with which it has undoubtedly been confounded by many writers.

Cancer ruricola of Linné. *Ocypode tourlourous* of Latreille.

Cordata. *Sp.* 3. *Cordata.* Shell as in the two foregoing species, with the sides gently sloping; tarsi with four elevated lines, which are serrated.

Inhabits the same country with the two preceding species.

Cancer corpatus of Linné. *Ocypode cordata* of Latreille.

Ceratophthalma. *Sp.* 4. *Ceratophthalma.* Shell of a rhomboidal-square form; arms granulated; hands cordated; with the apex of the peduncles of the eyes produced beyond them into a smooth spine.

Inhabits the shores of the East Indies and Mediterranean.

Ocypode ceratophthalma of Fabricius and Latreille; *Cancer ceratophthalmus* of Pallas, and probably *Cancer cursor* of Linné.

Colour, when alive, light, prettily mottled with reddish brown. About sunset it comes up the shores and wanders about the strand, running at intervals with great velocity. The right claw is commonly larger than the left, and both are equally rough.

Vide Index, *Ocypode, Goneplat,* and *Gecarcinus.*

Vocans *Sp.* 5. *Vocans.*

This species, of which Linné has given a very imperfect character, is said to inhabit Jamaica, where it conceals itself under stones, and when caught emits a cry. It grows to the size of three inches in diameter.

Cancer vocans of Linné; *Cancer vocans major* of Herbst; *Ocypode maracoani* of Latreille.

Another species allied to this is figured by Herbst; it apparently differs in nothing but size from the above, and may probably be the young of it.

Angulata. *Sp.* 6. *Angulata.* Shell nearly quadrate; armed near the anterior angle with one spine, (sometimes two, one behind the other).

Colour red; eyes half the length of the shell. Arms of the male about five times the length of the body; those of the female only twice.

Inhabits the western coast of Britain. First noticed as British by Mr Pennant; it has since been taken in great abundance in Salcombe Bay, Devonshire, by George Montagu, Esq. F.L.S.

Cancer angulatus of Linné, Fabricius, and Pennant. *Ocypode bispinosa* of Lamarck; *Goneplat bispinosa,* Leach, MSS. *Vide Goneplat* in Index.

Mus. Donovan, Leach, Montagu, Sowerby.

20. Grapsus. Genus XX. Grapsus. Eyes with a short peduncle, inserted at the anterior angles of the shell, which is depressed and quadrangular. Interior antennæ hid by the clypeus, which is inflexed.

Pictus. *Sp.* 1. *Pictus.* Shell with four tooth-like folds in the anterior part; fingers concave at the apex; a strong tooth on the inner wrist.

Inhabits South America and the West India islands.

Cancer grapsus of Linné and Fabricius.

It is rather rare. The colour is whitish, variously but beautifully varied with red, or red spotted with white, sometimes with minute red dots and streaks on a white ground, the speckled appearance pervading the whole upper surface of the thorax and legs. The hand claws are comparatively very small, rough, and of a rufous colour, bordered with white; body beneath pale.

Obs. Cancer tenuicrustatus of Herbst, of which he figures a large and small variety, (probably the sexes), is merely a variety of this species.

Varius. *Sp.* 2. *Varius.* Front of the shell with four folds; arms short; the extremities of the fingers concave.

Inhabits the Mediterranean Sea.

Grapsus varius of Latreille, on whose authority it is here inserted.

Cruentatus. *Sp.* 3. *Cruentatus.* Front of the shell with four smooth folds; fingers conical; wrists tuberculated and spiny.

Inhabits South America.

Grapsus cruentatus of Latreille.

21. Plagusia. Genus XXI. Plagusia. Eyes with a very short peduncle affixed to the anterior angles of the shell, which is quadrangular. The anterior antennæ fixed into two little foveolæ on the upper part of the clypeus.

Clavimana. *Sp.* 1. *Clavimana.* Hands clubbed; shell depressed, with the front of the clypeus and sides of the shell with four teeth.

Inhabits the Indian ocean.

Plagusia clavimana of Latreille. *Seba Mus.* tom. 3. fig. 21.

Depressa. *Sp.* 2. *Depressa.* Shell depressed, the sides on each side with five, and the middle of the clypeus with two teeth; the tubercles on the back naked.

Inhabits the shores of the Mediterranean.

Cancer depressus of Fabricius; *Plagusia depressa* of Latreille.

Squamosa. *Sp.* 3. *Squamosa.* The tubercles on the back ciliated; the sides of the shell with five, and the middle of the clypeus with two, dentiform processes.

Its habitation is unknown.

Plagusia squamosa of Latreille.

Semicylindrica. *Sp.* 4. *Semicylindrica.* Shell elevated; sides without teeth.

Inhabits the Indian ocean.

Cancer semicylindricus of Fabricius; *Plagusia semicylindrica* of Latreille, who is of opinion that this species and *Cancer auritus* of Fabricius, (both species unknown to us), should constitute a distinct genus.

22. Pinnotheres. Genus XXII. Pinnotheres. Shell roundish square, or oval round. The internal double palpi joined at their base.

The animals of this genus inhabit bivalve shells; and some of the species were known to the ancients, who believed them to have been the consentaneous inhabitants of the pinnæ and other bivalve shells; which being too stupid to perceive the approach of their prey, were warned of it by their vigilant friend. Oppian tells the fable prettily:

> In clouded deeps below, the *pinna* hides,
> And through the silent paths obscurely glides;
> A stupid wretch, and void of thoughtful care,
> He forms no bait, nor lays the tempting snare;
> But the dull sluggard boasts a crab his friend,
> Whose busy eyes the coming prey attend:
> One room contains them, and the partners dwell
> Beneath the convex of one sloping shell;

Deep in the wat'ry vast the comrades rove,
And mutual interest binds their constant love;
That wiser friend the lucky juncture tells,
When in the gaping circuit of hill shells
Fish wandering enter; then the bearded guide
Warns the dull mate, and pricks his tender side;
He knows the hint, nor at the treatment grieves,
But hugs th' advantage, and the pain forgives;
His closing shells the *pinna* sudden joins,
And twixt the pressing sides the prey confines.
Thus fed by mutual aid, the friendly pair
Divide their gains, and all the plunder share.

Pisum. *Sp.* 1. *Pisum.* Shell orbicular, of a reddish colour; hands oblong.

Plate CCXXI. Fig. 3. Inhabits various species of mussels. In one hundred of *Mytilus modiolus*, Mr Leach found three of this species. Male unknown. See Plate CCXXI. Fig. 3.

Varians. *Sp.* 2. *Varians.* Shell of an oval-round, somewhat narrow in front, very convex, solid and marbled; hands oval; fingers arched. Female unknown.

Pinnothère des moules. Latreille *Hist. Nat. des Crust. et des Ins.* tom. vi. p. 83. pl. 48.

Cancer varians. Oliv. *Encycl. Meth. Hist. Nat.* t. vi. p. 155.

Pinnotheres mytilorum. Latr. *Gen. Crust. et Ins.* vol. i. p. 35.

It is highly probable that *Cancer pinnophylax* and *Pinnotheres* of Linné belong to this genus. They are unknown to all the naturalists of the present time. See *Pinnotheres mytili, modioli, pinnæ, pisum, varians,* and *mytilorum* in the Index, as we have obtained some interesting facts lately, respecting the genus and its species.

* *All the feet with conic tarsi.*

FAMILY VIII. OXYRHYNCHI.

Observation. It is very evident that *Cancer rhomboidalis* of Montagu (*Linnean Transactions*, vol. vii. tab. 6. p. 84.) belongs to this family, but is not referable to any genus hitherto established; and as a specimen of it has never come under our inspection, we shall describe it in his own words.

"*Cancer rhomboidalis*: with an uneven rough thorax, destitute of spines, but furnished with three large tubercles on the fore part, and two others near the tail: front, a broad thin concave plate, projecting into a long sharp-pointed proboscis: antennæ two, setaceous, longer than the proboscis: eyes vastly large, prominent, reticulated, pedunculated, nearly half the diameter of the thorax; arms large in proportion, smooth; on the first joint beneath, a hooked spine turning upwards; fangs toothed; legs eight, subulate, a long spine on the first joint of each, underneath; tail nearly as long as the body, slender, cylindric-depressed, formed with five joints; the end truncated, hirsute: colour, when alive, light olive-green. Length from the point of the proboscis to the end of the tail, a quarter of an inch. Found amongst *sertulariæ* or the back of *Cancer dodecos.*"

23. Leucosia. GENUS XXIII. LEUCOSIA. Shell somewhat oval and convex. (The greater part in most of the species smooth.) The double external palpi with equal narrow footstalks; the second joint narrowing towards the point, and reaching the anterior margin of the shell. *Antennæ and eyes minute.*

Nucleus. *Sp.* 1. *Nucleus.* The clypeus with two teeth-like processes in front: the posterior margin of the shell with two folds and a minute spine on the upper side; arms of an equal size and elongated.

Inhabits the Mediterranean Sea.

Cancer nucleus of Linné; *Leucosia nucleus* of Fabricius and Latreille.

Sp. 2. *Craniolaris.* Shell granulated; anterior part depressed above, posterior margin wrinkled, without spines; one tooth-like process in the middle of the clypeus; arms warty beneath; hands cylindrical and compressed; fingers conical, the internal side with sharp teeth. Craniolaris.

Inhabits the shores of Malabar.

Cancer craniolaris of Linné; *Leucosia craniolaris* of Fabricius and Latreille.

GENUS XXIV. MAIA. Shell nearly triangular, (generally rough and rostrated in front.) The internal footstalk of the external double palpi with two broad joints. Space between the eyes very wide. Feet nearly equal in size and shape: *the hinder feet being neither small nor spurious.* See *Ilyas Inachus,* in the Index. 24. Maia.

Division I. Arms very thick, and extending in a right angle.

Sp. 1. *Horrida.* Shell spinous, the upper surface very unequal and irregular: tail as if worm eaten; hand oval. Horrida.

Inhabits the Asiatic Ocean.

Cancer horridus of Linné; *Parthenope horrida* of Fabricius; *Maia horrida* of Latreille.

It is described by Petiver under the name of the great warty crab; is the *Rotskrabbe* of Rumphius, the *Die schreckliche* of Herbst.

For *Cancer horridus* of Pennant, see *Lithodes maja, Genus* 26.

Sp. 2. *Giraffa.* Shell spiny, with the spines branched: hind claws very long and tuberculated beneath. Giraffa.

Inhabits the East Indies.

Cancer giraff of Fabricius.

Sp. 3. *Muricata.* Shell unequal and hairy, with a double line and two dorsal spines on each side; marginal spines four; legs hairy. Muricata.

Habitat unknown.

Cancer muricatus of Fabricius. *Ent. Syst.*

Division II. Arms extended forwards, and not remarkably thick.

* Second pair of feet neither three times the length of the body, nor very slender.

Sp. 4. *Araneus.* Thorax rough and tuberculated; rostrum bifid; claws oval. Araneus.

Inhabits the European seas, frequenting all our sandy coasts, particularly the mouths of rivers, where it resides in deep water, and is taken by the oyster dredgers, who name it harper or spider crab; and, as they suppose it injurious to the beds, always bring it ashore and destroy it. It is very frequently covered with bernacles, alcyonia, sponges, fuci, and other marine substances. Its common size is about ten inches across from the tip of one arm to the other, but it sometimes measures sixteen from these points. The arms of the male are considerably longer than those of the female. It spawns during the greater part of the year.

Cancer araneus of Linné and Pennant.

Sp. 5. *Armata.* Shell of an elongated triangular form, hairy, with three dents behind; clypeus with two strong spines; hands elongated. Armata.

Màia armata of Latreille. *Inachus opilio* of Fabricius.

Inhabits the Mediterranean Sea.

Sp. 6. *Squinado.* Shell rough; the front with two spines, the sides with six elongated conic spiny processes: the arms scarcely longer than the following pair of feet; hands cylindrical and smooth; fingers tuberculated. Squinado.

Crustacea. *Cancer maja* of Scopoli. *Cancer spinosus*, Oliv. *Encycl. Method. Hist. Nat.* tom. vi. p. 173. *Maja squinado* of Latreille.

Inhabits the Mediterranean Sea.

To this division belong *Cancer asper*, *Dorsettensis*, and *Tetraodon* of Pennant's British Zoology.

** Second pair of feet very slender, and three times the length of the body.

Sagittaria. *Sp.* 7. *Sagittaria.* Rostrum very long, and surrounded by spines; feet spiny, arms elongate.

Maja sagittaria of Latreille. *Inachus sagittarius* of Fabricius.

Inhabits the island of Guadaloupe.

Phalangium. *Sp.* 8. *Phalangium.* Rostrum long and bifid, contracted at its base. Shell somewhat hairy, with three acute spines in the anterior part, obtuse tubercles behind: snout bifid.

Inhabits the northern seas, and is very abundant on many of our coasts, being frequently taken by the oyster dredgers, who imagine it to be the young of araneus.

Plate CCXXI. Fig. 4. *Cancer phalangium* of Pennant. *Leptopodia phalangium*, Leach's MSS. See Plate CCXXI. Fig. 4. and Appendix.

25. Macropodia. Genus XXV. Macropodia. Shell nearly triangular (unequal and rostrated in front;) external double palpi narrow and porrected: the second joint of the internal peduncle pretty long. Eyes distant: feet alike, *the hinder ones neither spurious nor minute.*

Longirostris. *Sp.* 1. *Longirostris.* Shell hairy, with three erect spines on the front; the hinder part with obtuse tubercles; rostrum bifid.

Cancer dodecos of Linné?

Inachus longirostris of Fabricius. *Macropus longirostris* of Latreille. *Macropodia longirostris*, Leach's MSS.

26. Lithodes. Genus XXVI. Lithodes. Shell nearly triangular and unequal, the anterior part rostrated. The external double palpi with narrow cylindrical footstalks. Eyes near each other at their base, but diverging above the shell. Hinder feet minute and spurious.

Maja. *Sp.* 1. *Maja.* Claws, feet, and shell spiny; rostrum spiny, with the apex bifurcate: flesh-coloured when alive.

Inhabits the northern and British seas. It is very rare in this country, being found only on the rocky coasts of Yorkshire and Scotland. It has been mistaken by Pennant for *Cancer horridus* of Linné, which we have already shown to belong to a distinct genus. *Vid. Gen.* 24. *Maia horrida.*

Cancer maja of Linné. *Inachus maja* of Fabricius. *Lithodes arctica* of Latreille. *Cancer horridus* of Pennant.

Mus. Donovan, Montagu, Neill, Leach, Fleming, Sowerby.

27. Corystes. Genus XXVII. Corystes. Shell somewhat oval. External antennæ porrected, as long as the body. The second joint of the internal peduncle of the external double palpi lengthened, and gradually narrowing towards the apex. Arms of the male three times the length of the body.

Cassivelaunus. *Sp.* 1. *Cassivelaunus.* Thorax rugulose, with four teeth on each side. Wrists with two or three spines. *Cancer cassivelaunus* of Pennant.

Inhabits all the sandy shores of our island, where it is frequently cast ashore, after a brisk gale of wind. Between the second and third spine, there is a small projecting process. Colour, when alive, flesh red.

Obs. Coristes longimanus of Latreille is merely the male of this species.

28. Mictyris. Genus XXVIII. Mictyris. Shell nearly oval, elevated, and truncated behind. Antennæ short. The basilary joint of the internal footstalk of the external double palpi very large. Arms at the base of the wrist jointed.

Longicarpus. *Sp.* 1. *Longicarpus.* Body nearly oval, thick, rather narrower in front, truncated behind, soft, and of a pale yellow colour. Length about nine lines. Shell with two longitudinal impressed lines; the anterior margin inflexed and rounded, and lateral external angles (as in some of the *Ocypodes*) produced into a tooth behind the eyes; the posterior margin ciliated with short black hairs. Eyes globular, with a short peduncle, placed under the anterior margin of the shell, (as in the *Ocypodes.*) Arms exserted forwards and downwards; the base of the second joint internally with a strong spine; the next joint triangular, the apex below being armed with three little processes. The wrist lengthened, somewhat arched, and hairy on the inside. Hand short, much compressed, with elevated lines. Fingers elegantly lengthened. Thumb with a strong single tooth. The other feet twice as long as the body, and much compressed; the tarsi furrowed and compressed; the second and first pair the largest, and nearly of an equal size.

Inhabits the East Indies. This rare and curious animal was first described by the French author Latreille, (whose system we are nearly following,) from a specimen in the Parisian Museum of natural curiosities. Our description is made from his, and the MSS. of Mr Leach, who described it from a specimen in the collection of the Royal College of Surgeons, London; and who had not seen Latreille's work at the time he drew up his description.

29. Dorippe. Genus XXIX. Dorippe. Shell somewhat oval, depressed, narrow before, and truncated. The four posterior feet dorsal; the last joints shortest.

Quadridens. *Sp.* 1. *Quadridens.* Middle of the clypeus with four teeth; those placed externally shortest. Sides of the shell with one tooth; the four anterior thighs somewhat notched.

Cancer lanatus of Linné; *Dorippe quadridens* of Latreille and Fabricius.

Inhabits the Mediterranean Sea, and figured by Plancus.

*** Some of the feet formed for swimming, the last joint being compressed and foliated.

30. Orithyia. Genus XXX. Orithyia. The two hinder feet alone formed for swimming.

Mamillaris. *Sp.* 1. *Mamillaris.*

Orythia mamillaris of Fabricius and Latreille, on whose authority we have inserted it here. They refer to a figure in *Herbst*, tab. 18. fig. 101.

Inhabits the Indian Ocean.

31. Matuta. Genus XXXI. Matuta. All the feet, with the exception of the brachia, inserted in the same horizontal line, and furnished for swimming.

Victor. *Sp.* 1. *Victor.* Shell punctured on all sides, but not striated behind.

Matuta victor of Fabricius and Latreille.

Inhabits the Indian Ocean.

Herbstii. *Sp.* 2. *Herbstii.* Shell with impressed dots; deeply striated behind.

Matuta Herbstii, Leach's MSS.

A new species, described in the manuscripts of Mr William Elford Leach, from a specimen in the British Museum, and named by him, after the celebrated crustaceologist Herbst, author of a large work in the German language, entitled *Von Krabben,* illustrated with correct plates.

Crustacea.

32. Ranina. Genus XXXII. Ranina. All the feet, except the brachia or arms, formed for swimming, two pair being placed above the others. Hand without the thumb; the finger much bent or arched; hands from the base to their extremities, gradually broader and much compressed.

Serrata. *Sp.* 1. *Serrata.* Arms very spiny; anterior margin of the shell with toothed lobes.

Cancer raninus of Linné and Fabricius; *Ranina serrata* of Latreille.

Inhabits the Indian Ocean.

Dorsipes. *Sp.* 2. *Dorsipes.* Anterior margin of the shell with seven teeth; the hands with a few tooth-like processes.

Cancer dorsipes of Linné; *Albunea dorsipes* of Fabricius; *Ranina dorsipes* of Latreille.

Family IX. Pagurii.

* Peduncle of the anterior antennæ much shorter than the two articulated setæ. Hands with one finger or none. Some of the feet formed for swimming, the last joint being compressed and leaf-shaped.

33. Albunea. Genus XXXIII. Albunea. Hands with one finger. Hinder feet minute, filiform, and spurious; the last joint of the other feet compressed and hooked.

Symnista. *Sp.* 1. *Symnista.* Anterior part of the shell smooth.

Cancer symnista, Linné; *Albunea symnista* of Fabricius and Latreille.

34. Remipes. Genus XXXIV. Remipes. Arms shorter than the second pair of feet; last joint hooked. The upper part rather convex. The feet, with the exception of those mentioned, formed for swimming.

Testudinarius. *Sp.* 1. *Testudinarius.* Shell about an inch in length, rather oval, of a reddish yellow colour, finely wrinkled; the anterior part with five teeth, the middle being shortest. Eyes placed on a very slender cylindrical peduncle, and inserted under the lateral teeth of the anterior margin. The middle antennæ somewhat bent backwards, ciliated with fine hair, and furnished with a thick peduncle. The exterior antennæ bent inwards under the others, with its peduncle flattened and jointed, having an elongated hairy footstalk.

Remipes testudinarius, Latreille; *Hippa adactyla* of Fabricius?

Inhabits New Holland.

35. Hippa. Genus XXXV. Hippa. Hands compressed, oval, and simple. The tarsus of the second and third pair of feet lunated; of the fourth triangular (rarely subquadrate); the posterior feet minute, spurious, and filiform.

Emeritus. *Sp.* 1. *Emeritus.* Tail inflexed; the last joint oval.

Cancer emeritus of Linné? *Hippa emeritus* of Fabricius and Latreille.

Inhabits the Indian Seas.

** Peduncle of the interior antennæ longer than the two articulated setæ. Feet formed for walking. The tarsi conic. Hands compound, furnished with a finger and thumb.

36. Pagurus. Genus XXXVI. Pagurus. This being the only genus of the division hitherto discovered, no generic character is necessary. All the species are parasitical, inhabiting the empty cavities of turbinated shells, the animals of which they are supposed to attack and devour, to gain possession of their shell. They change their habitation with their growth, first occupying the shells of the common periwinkle or trochus, then perhaps a nerite as large as a walnut, and after that a whelk. The tail is naked and slender, being covered only with a skin of very delicate texture; but it is furnished at the extremity with one or more hooks, by means of which it secures itself to the shell which it makes choice of. It is really astonishing with what facility these animals move, bearing at the same time the shell, which serves them as a covering, on their back. All the species are termed indiscriminately *Soldier-crabs* and *Hermit-crabs*, from the idea of their living in a tent, or retiring to a cell.

Crustacea.

Bernhardus. *Sp.* 1. *Bernhardus.* Arms hairy and rough, the right (generally) largest; hands somewhat heart-shaped; fingers broad. The appendix of the exterior antenna somewhat produced.

Cancer bernhardus of Linné and Pennant. *Pagurus bernhardus* of Fabricius and Latreille.

The common soldier-crab of our seas. It was not unknown to the ancients; Aristotle has very accurately described it under the name καρκίνιον.

A variety with equal claws sometimes occurs. It is considered by the vulgar as the young of the common lobster; it rarely exceeds six inches in length, from the tip of the claw to the tail.

Araneiformis. *Sp.* 2. *Araneiformis.* Resembling the foregoing species, but only one fourth its size.

Inhabits the shells of smaller univalve testacea. It is not uncommon in the Frith of Forth, where it was first observed by Charles Stewart, Esq. and described by him in a work entitled Elements of Natural History, under the name *Cancer araneiformis.* It differs from the foregoing species merely in size; and is considered by Mr Leach, who found several of them *in spawn* (at Porto-Bello near Edinburgh, after a hard easterly wind, and now has them in his collection) as the young of *Bernhardus;* most of the crustacea having the power of producing young before they attain their full growth.

Latro. *Sp.* 3. *Latro.* Shell at the suture four-cleft; tail simple and ventricose beneath.

Cancer latro of Linné.

Inhabits the East Indies, living in holes and cavities of rocks, from whence it wanders abroad in the night, and is said to climb cocoa-nut trees, in order to procure the fruit, which it throws down, and then descending tears them open with the two fore claws. The flesh is eaten by the natives after the entrails are removed, which they think poisonous. Probably referable to another genus.

Diogenes. *Sp.* 4. *Diogenes.* Hands rough and pubescent; left hand largest.

Pagurus diogenes of Fabricius. *Cancer diogenes* of Gmelin.

Inhabits the Indian seas, and is called by the natives *Gami na al Koona.* The general colour when alive is pale-testaceous, or yellow-brown.

"It is very diverting to observe this animal when about to change its shell, at which time it is seen busily parading the shore along that line of pebbles and shells which is formed by the extremest wave; still, however, dragging its own incommodious habitation at its tail, unwilling to part with one shell, even though a troublesome appendage, till it can find another more convenient. It is seen stopping at one shell, turning it and passing it by; going on to another, contemplating that for a while, and then slipping its tail from its old habitation to try on the new; this also is found inconvenient, and it quickly returns to its old shell again. In this manner it frequently changes, till at last it finds one light, roomy, and commodious; to this it adheres, though the shell be sometimes so large as to hide the body of the animal, claws and all. Yet it is not till after many trials and many combats also, that the soldier is thus completely equipped: for there is often a contest between two of them for some well-looking favourite shell for which they are rivals. They endeavour both to take possession; they strike with their claws, they bite each other till the weakest is obliged to give up the object in dispute. It is then the victor immediately takes possession, and parades in his new conquest three or four times back and forward upon the strand before his envious antagonist."

When taken, it is said to utter a feeble cry, endeavouring to seize the enemy with its nippers; which, if it fastens upon, it will sooner die than quit the grasp.

They frequent those parts of the sea-shore which are covered with shrubs and trees, producing various wild fruits, on which they subsist; though they will also feed on garbage of all kinds when much in want of food. When roasted in the shell they are esteemed delicate food.

Custos.

Sp. 5. *Custos.* Left claw largest; hand smooth; legs with very long smooth claws.

Pagurus custos of Fabricius, described by him from a specimen in the museum of Daldorff; much akin to the following species, but distinct.

Inhabits the East Indies.

Miles.

Sp. 6. *Miles.* Left hand largest; hand rough and tuberculated on each side; legs with very long serrated claws.

Pagurus miles of Fabricius.

Inhabits the East Indies.

Aniculus.

Sp. 7. *Aniculus.* Thorax ovate, ciliated at the sides; legs rugose and hairy.

Pagurus aniculus of Fabricius, described from a specimen in the Banksian cabinet.

Inhabits the South Seas.

Tubularis.

Sp. 8. *Tubularis.* Body nearly cylindrical; shell with excavated dots.

Cancer tubularis of Linné. *Pagurus tubularis* of Fabricius.

A native of the Mediterransan Sea, inhabiting the shell of *Serpula glomerata.*

Oculatus.

Sp. 9. *Oculatus.* Hands equal and rough; peduncles of the eyes as long as the thorax, with a small tooth at the base. Arms with a blood red spot on each.

Pagurus oculatus of Fabricius.

Inhabits the empty shell of *Murex brandaris,* and is about six inches in length when full grown.

latus.

Sp. 10. *Alatus.* Hands smooth, with three wing-like processes; right hand largest.

Pagurus alatus of Fabricius.

This species was discovered in Iceland by Dr Köenig. It is rather smaller than *Pagurus bernhardus*; under side of the wrist rugose.

Canaliculatus.

Sp. 11. *Canaliculatus.* Hands and wrists grooved, with elevated serrated margins; legs with hairy tufts.

Cancer canaliculatus of Herbst.

The habitat of this species is very doubtful.

Family X. Palinurini.

* The two anterior feet simple, with conic tarsi, rather larger than the others, but of the same form. Hand, without the finger. Exterior antennæ not inserted behind the eyes.

37. Scyllarus.

Genus XXXVII. Scyllarus. Exterior antennæ with broad squamiform joints, resembling a crest. Eyes distant.

Latus.

Sp. 1. *Latus.* Shell granulated; squamiform joint of the external antennæ entire.

Scyllarus latus of Latreille, who supposes it to be distinct from *Scyllarus australis* of Fabricius; and as this is the opinion of the London collectors also, we have followed him in giving the above name, and adopted it as a distinct species.

Australis.

Sp. 2. *Australis.* Plates of the antennæ roundish and smooth.

Discovered in the South Seas by Sir Joseph Banks, from whose collection Fabricius drew the above vague description; and as the plates of the antennæ were taken away by Fabricius, we cannot pronounce, with that degree of certainty we could wish, this to be really sufficiently distinct from *Scyllarus latus.*

Arctus.

Sp. 3. *Arctus.* Plates of the antennæ aculeated and hairy; the anterior part of the shell in front, with five spines.

Cancer arctus of Linné. *Astacus arctus* of Pennant. *Scyllarus arctus* of Fabricius and Latreille.

Inhabits the European ocean. It is rather larger than *Astacus marinus* (the common lobster). The shells are tuberculated, of a brown colour, spotted with yellow; legs spotted; thighs spinous.—It is very rare in England, if ever found on the coast, which we doubt.

Tridentatus.

Sp. 4. *Tridentatus.* Shell dentated above; the squamiform of the external antennæ with three strong teeth.

Its habitat is unknown. The above description was copied from the manuscripts of Mr William Elford Leach, who observed it in the collection of William Comyns, Esq. of Mount Pleasant, near Dawlish, Devonshire.

Observation. Fabricius has described three other species under this genus, which being unknown to British collectors, and unnoticed by other authors who have written on this branch of natural history, we can only describe them in the words of the author.

Antarcticus.

" *Sp.* 5. *Antarcticus.* Rough and hairy; thorax and plates of the antennæ serrated and ciliated. Inhabits India.

Æquinoctialis.

" *Sp.* 6. *Æquinoctialis.* Rough; thorax and plates of the antennæ wrinkled. Inhabits South America.

Orientalis.

" *Sp.* 7. *Orientalis.* Rough; anterior part of the thorax on each side armed with three spines. Inhabits the East Indies."

38. Palinurus.

Genus XXXVIII. Palinurus. External antennæ very long and setaceous. Peduncle of the eye transversely broad.

Vulgaris.

Sp. 1. *Vulgaris.* Spines placed over the eyes, which spines are dentated below; the segments of the abdomen with a transverse impressed line, which is interrupted in the middle.

Palinurus quadricornis of Fabricius. *Palanuris vulgaris* of Latreille.

Inhabits the Mediterranean Sea.

Homarus.

Sp. 2. *Homarus.* Thorax prickly on the anterior part, with two spines in front; base of the antennæ spinous.

Cancer Homarus of Linné. *Astacus homarus* of Fabricius.

Inhabits our rocky coasts, is taken for food, and commonly sold in London under the name of Thorny Lobster.

Astacus homarus of Pennant.

** Two anterior feet different from the rest, being furnished with a finger and thumb; hand compressed; hinder feet minute. Exterior antennæ inserted behind the eyes. The middle lamella of the tail either divided into two by a longitudinal groove, or the posterior margin notched.

39. Porcellana.

Genus XXXIX. Porcellana. Shell of a roundish square form. The internal side of the basilary joint of the internal footstalk of the external double palpi, dilated.

Hexapus.

Sp. 1. *Hexapus.* The anterior margin of the shell

Crustacea. with three wrinkled processes; the middle tooth being deeply notched. Arms smooth.

Cancer hexapus of Linné and Fabricius. *Porcellana hexapus* of Latreille.

Inhabits the European Ocean; is very common on our coasts, being frequently thrown ashore after a storm, adhering to the roots of *Fucus digitatus*.

Longicornis. *Sp.* 2. *Longicornis.* Clypeus with three wrinkled teeth, the middle tooth being entire. Arms striated.

Cancer longicornis. Linné.

Inhabits the European Ocean.

Platycheles. *Sp.* 3. *Platycheles.* Anterior margin of the shell with three entire teeth; the arms very large; the internal sides of the wrists with teeth; hands externally ciliated.

Cancer platycheles of Pennant, *Porcellana platycheles* of Latreille.

Inhabits the European Ocean.

It was discovered by Mr Pennant in Anglesea and the Hebrides, and described by him in his British Zoology. Some naturalists have supposed it to be *Cancer hexapus* of Linné. It is found on the coast of Devonshire at low tide, adhering to the under side of large stones.

40. Galathea. Genus XL. Galathea. Shell oval. The basilary joint of the internal peduncle of the external double palpi, neither plain nor dilated on its internal margin.

Strigosa. *Sp.* 1. *Strigosa.* Upper part of the hands, wrists, and arms ciliated with spines on every side: under side of the hands as if plaited; hairy between the fingers; rostrum with seven dents.

Cancer strigosus of Linné and Pennant. *Galathea strigosa* of Fabricius and Latreille.

Inhabits the European Ocean; is very common on several of our rocky coasts, being known by the name of *Plaited Lobster.* It is very active, and when taken, flaps its tail against its body with great violence and noise. Upper part when alive, brown inclining to reddish brown, with the sutures blue. Length six inches.

Squamifera. *Sp.* 2. *Squamifera.* Hands plaited, with their external margin spiny; wrists and arms plaited, internal margin armed with strong spines. Rostrum with seven dents.

Inhabits England.

Astacus squamifer. Montagu's MSS.

A new species discovered by Montagu on the south coast of Devon, where it is by no means uncommon. The above characters will point out their specific characters with sufficient accuracy. It has probably been confounded with *Galathea strigosa,* from which it is however very distinct. Length five inches.

Bamfia. *Sp.* 3. *Bamfia.* Thorax anteriorly wrinkled and spiny; rostrum with three teeth: arms very long and slender.

Galathea rugosa of Fabricius, *Astacus bamfius* of Pennant, *Cancer rugosus* of Gmelin.

Inhabits the European Ocean.

It was discovered in this country by the Rev. Mr Cordiner, near Banff, and sent to Mr Pennant; two others have since occurred on the same coast, which are preserved in the collections of Donovan and Sowerby. Length of tail and body five inches; arms six inches and a half.

Observe. Two other species are described under this generic title by *Fabricius,* but as they have never come under our inspection, we conceive it better to describe them in his words; as they may be referable to some other genus.

Gregaria. " *Sp.* 4. *Gregaria.* Thorax with ciliated plates; snout with three teeth; anterior feelers very long. *Fabricius.* Much smaller than the preceding species (*i. e. Galathea strigosa* and *rugosa.*)

" Inhabits the sea round Patagonia, where it occurs in such vast shoals that the sea appears perfectly red; that being the prevailing colour of them when alive: it has a brown spot on the back; hand claws rough. *Donovan.*

" *Sp.* 5. *Amplectens.* Thorax smooth; rostrum very short and notched; middle pair of legs very long. The body is small, whitish, and transparent, dotted with red. Thorax smooth, roundish behind, and broad, narrowing towards the front; four cetaceous antennæ, which are very long; abdomen of five segments; middle process or lamella of the tail tongue-shaped. Amplectens.

" This kind is luminous at night; it inhabits the Atlantic near the coast of Brasil." *Fabricius.*

Family II. Astacini.

Division 1. Hands compound, that is furnished with a finger and thumb.

* Antennæ inserted under the eyes, furnished with two articulated setæ.

Genus XLI. Astacus. Antennæ inserted in nearly the same transverse horizontal line; the peduncle of the exterior either supported by a small lamella or none. Six anterior feet compound; the anterior ones largest. The middle table of the swimming tail-fin broader at the base than at the apex. 41. Astacus.

In *A. gammarus* and *fluviatilis* the external antennæ are simple, in *Norvegicus* furnished with a scale at their external base: this last is considered as a distinct genus by Mr Leach, under the name of *Nephrops,* from the kidney shaped eye.

Sp. 1. *Gammarus.* Shell, tail, and feet, smooth, beautifully studded with minute excavated dots. Sides of the rostrum with four or more teeth, a strong tooth likewise at the base on each side. Eyes globose, or rather hemispherical. Hands with four, five, or six teeth on their internal margin. Tarsi beautifully ornamented with tufts of hair. Exterior lamella of the tail, at the junction of the accessory plate, with distinct obtuse spines. Ciliæ of the tail testaceous. Colour, when alive, purplish-black, often inclining to violet, elegantly mottled, (particularly on the under side,) with white; cream white and reddish. One claw always larger than the other; the fingers of one armed internally with minute teeth, of the other with tubercles. Gammarus.

Cancer gammarus of Linné. *Astacus gammarus* of Pennant. *Astacus marinus* of Fabricius and Latreille.

The middle lamella of the tail, in the *male* with the apex nearly straight, in the *female* rounded.

Inhabits the European Ocean; is the common lobster of our markets. It is found in great abundance on the north coast of Scotland, particularly amongst the Orkney Isles; but it is far more frequent on the coast of Norway, from whence the metropolis is well supplied at most seasons of the year, and these are generally preferred for the table.

Little can be said with regard to the natural history of the *lobster* beyond what has already been stated by Mr Pennant, and his friend Mr Travis of Scarborough. We shall therefore avail ourselves of the observations of these gentlemen, and detail at full length all they have remarked, but we cannot vouch for the perfect accuracy of all their observations.

" The habitation of this species is in the clearest water at the foot of rocks which impend over the sea. This has given opportunity of examining more closely into the natural history of this animal than many others, who live in an element that prohibits most of the human researches, and limits the inquiries of the most inquisitive: Lobsters are found on most of the shores of

Great Britain. Some are taken by the hand, but the far greater number in pots, a sort of trap formed of twigs, and baited with garbage, (called *kreels*) formed like a mouse-trap, so that when the lobster gets in, there is no return. These are fastened to cords and sunk into the sea, and their place marked by a buoy.

"They begin to breed in the spring, and continue breeding most part of the summer. They are highly prolific; Dr Baster counted 12,444 eggs under the tail of one female, besides those which remained in the body unprotruded. They deposit these eggs in the sand, where they are very soon hatched."

"Lobsters change their crust annually, and previous to their putting off their old one, they appear sick, languid, and restless. They totally acquire a new coat in a few days; but during the time they remain defenceless, they seek some very lonely and remote place, lest they should be devoured by such of their brethren as are not in the same weak situation." *Pennant.*

They are exceedingly voracious animals, and feed on all sorts of dead bodies, sea-weeds, or garbage.

Some very interesting particulars were communicated to Mr Pennant by Mr Travis, from a variety of observations made by himself on the coast of Scarborough. "Lobsters," he observes, "are found in great abundance and very fine on that coast. The larger ones are in general, in their best season, from the middle of October till the beginning of May. Many of the small ones, and some of the larger sort, are good all the summer. They are, in general, from four to four inches and a half from the tip of the head to the extremity of the back shell. Commonly the pincers of one of the lobster's large claws are furnished with knobs, and those of the other serrated; with the former, it keeps firm hold of the stalks of submarine plants, and with the other it cuts and minces its food very dexterously. The knobbed or numb-claw, as the fishermen sometimes call it, is sometimes on the right side, and sometimes on the left indifferently. It is more dangerous to be seized by them with the cutting claw than the other, but in either case, the quickest way to get disengaged, is to pluck off the creature's claw; a new one will be produced in its place, though it will never attain the size of the former. The female or hen lobster, does not cast her shell the same year that she deposits her ova, or in the common phrase, *her berry*. When the ova first appear under her tail, they are very small, and extremely black, but they become in succession almost as large as ripe elder berries before they are deposited, and turn of a dark brown colour, especially towards the end of her depositing time. They continue full and depositing the ova in constant succession as long as the black substance can be found in their body, which, when boiled, turns of a beautiful red colour, and is then termed coral. Hen lobsters are found in berry all the year. It is a common mistake that a berried hen is always in perfection for the table. When her berries appear large and brownish, she will always be found exhausted, watery, and poor. Though the ova be cast all the year round, they seem only to come to life during the summer months of July and August. Great numbers of them may be then found under the appearance of *tadpoles* swimming about the little pools left by the tide amongst the rocks, and many also under their proper form, from half an inch to four inches in length.

"In casting their shells, it is hard to conceive how the lobsters are able to draw the flesh of their large claws out, leaving the shell entire and attached to their body; in which state they are constantly found. The fishermen say the lobsters pine before casting their shell, till the flesh of its large claw is no thicker than a goose quill, which enables them to draw its parts through the joints and narrow passages near the trunk. The new shell is quite membranaceous at first, but hardens by degrees. Lobsters only grow in size whilst their shells are in a soft state. They are chosen for the table by their being heavy in proportion to their size; and by the hardness of their shells on the sides, which, when in perfection, will not yield to moderate pressure. Barnacles, and other marine animals adhering to them, are esteemed certain indications of superior goodness. Cock lobsters are in general better than the hens in winter; they are distinguished by their narrow tails, and by having a strong spine upon the centre of each of the transverse processes beneath the tail, which support the four middle plates of the tails. The flesh of the lobster's claw is more tender and delicate than that of the tail. The Scarborough fishermen do not take them in pots or kreels, as is usual in still and deep waters; they use a bag-net, fixed to an iron hoop, about two feet in diameter, and suspended by three lines like a scale. The bait is usually fish-guts tied to the bottom and middle of the net. They can take none in the day-time except when the water is thick: they are most frequently taken at night, but even then it is not possible to take any when the sea has a luminous appearance: (This is accounted for, by James Macartney, Esq. in a paper given by him to the Royal Society, and published in the Philosophical Transactions for 1810, p. 292.) In summer, the lobsters are found near the shore, and thence to about six fathoms water; but in winter, they are seldom taken in less than twelve or fifteen fathoms. Like insects, they are much more active and alert in warm than in cold weather. In the water, they can run nimbly on their legs or small claws, and if alarmed, can spring tail foremost, to a surprising distance, as swift as a bird can fly." (This observation has been confirmed by that indefatigable observer of nature, Patrick Neill, Esq. secretary to the Wernerian and Horticultural Societies of Edinburgh, who, in a tour made by him to the Orkney Isles, says they skimmed along the surface of the sea with amazing rapidity as the boats approached the shore.) "The fishermen can see them pass about thirty feet, and by the swiftness of their motions, suppose they may go much farther. When frightened, they will spring from a considerable distance to their hold in the rock; and what is not less surprising than true, they will throw themselves into their holds in that manner through an entrance barely sufficient for their bodies to pass; as is frequently seen by the people who endeavour to catch them at Filey Bridge. In frosty weather, if any should happen to be found near the shore, they are quite torpid and benumbed."

Immense numbers of lobsters are annually sent to London from the Orkney Isles. Pennant mentions, in his Tour to Scotland in 1772, that 60,000 or 70,000 are yearly sent from Montrose alone. They are said to fear thunder, and to cast their claws on a great clap; it is said they will do the same on the firing of a great gun; and that when men of war meet with a lobster boat, a jocular threat is used, that if the master does not sell good lobsters, *they will salute him.* When frightened or irritated, they frequently throw off their claws; the same thing happens when the poor animals are plunged into the boiling pot for dressing. When first caught, if only taken by one claw, they will throw it off and so effect their escape.

The circumstance of the reproduction of their claws, though surprising, is nevertheless true; lobsters as well as crabs will renew their claws, if by accident they should be torn off, within the space of a few weeks after the mischief has happened.

A small lobter, according to Mr Pennant, differing in nothing but size from the above, is found near Llyn in Caernarvonshire, where it burrows in the sand; from which last circumstance, we suspect it to be distinct, and well worth the examination of any naturalist who may happen to visit that place.

The lobster was well known to the ancients, and is well described by Aristotle, under the name *αστακος*.

Fluviatilis. *Sp.* 2. *Fluviatilis.* Rostrum toothed. Hands tuberculated.

Cancer astacus of Linné. *Astacus astacus* of Pennant. *Astacus fluviatilis* of Fabricius and Latreille.

Inhabits the rivers of Europe, especially such as have a clayey bottom. It is the common *craw-fish* of English writers, and is much esteemed as food. They excavate holes for themselves in the banks of rivers in which they live, only coming abroad at night in search of food, which consists of vegetable as well as animal matters; they are taken by means of nets, which are spread across the waters which they frequent, or by the hand. Colour, when alive, dark brown approaching to black.

Norvegicus. *Sp.* 3. *Norvegicus.* Rostrum acute, with many spines on each side; shell somewhat spiny in front; from which three longitudinal ridges arise. Hands angular, the angles tuberculated. Wrists spiny. Eyes kidney-shaped. Tarsi hairy. Accessory process of the tail at the base acutely spined. Tail elegantly marked with smooth and short-haired spaces placed alternately.

Cancer norvegicus of Linné. *Astacus norvegicus* of Pennant. *Nephrops norvegica,* Leach's MSS.

Inhabits the northern parts of Europe; is found in the Frith of Forth during the summer months, often attaching itself to the lines of the fishermen. Like the common lobster, it has one claw large, the other small; a variety with equal claws sometimes occurs. Colour, when alive, flesh red.

42. Thalassina. Genus XLII. Thalassina. Antennæ inserted in nearly the same horizontal line. The four anterior feet compound, the first or front pair largest.

Scabra. *Sp.* 1. *Scabra.* Shell oval, sides compressed, and spiny. Back with two longitudinal furrows, one on each side; these converge towards the posterior margin, and include another very deep groove. Tail cylindrical, a little longer, and much narrower than the shell; composed of six segments (not including the fin) very convex above, with the lateral margin dilated, wrinkled, and rounded; the first five with an elevated carina or ridge, the fin segment with narrow, acute, and sharp appendices. The feet compressed, with the posterior and anterior margins denticulated; the four anterior feet ciliated with hairs; right arm largest; hands oval, and tuberculated, with teeth above and below; the thumb compressed and rounded. This genus was instituted by the illustrious Latreille, in his work entitled *Genera Crustaceorum et Insectorum,* who describes the above species from a specimen in the museum of natural history in Paris. Mr Leach has compared this description with a specimen in the Hunterian museum, and from his manuscript we have inserted the above account, which differs but little from that given by Latreille.

43. Upogebia. Genus XLIII. Upogebia. Antennæ inserted in nearly the same horizontal line. Eyes pedunculated, and concealed under the proboscis. Abdomen composed of quadrate crustaceous joints. Anterior feet compound, being furnished with a very long moveable thumb; feet compressed, decreasing in size, the anterior being largest. Middle process of the tail nearly quadrate, the apex being scarcely narrower than the base.

Stellata. *Sp.* 1. *Stellata.* Thorax smooth behind, the anterior part set with minute spines disposed in longitudinal rows, anterior part terminating in a broad and rough rostrum, on each side of which at the base is a strong spiny spire. Under part of the hands hairy, fingers very sharp; wrists and arms angulated, and set with hairs beneath and inside. Feet somewhat compressed. Extremity of the middle process of the caudal fin slightly notched; moveable processes, with an elevated ridge, in the middle. Length two inches. Colour yellowish white, covered with minute yellow or orange spots.

Cancer stellatus, Montagu; *Upogebia stellata,* Leach's MSS.

This animal was discovered by George Montagu, Esq. and described by him in the ninth volume of the *Linnean Transactions.* It is very rare, and inhabits the subterraneous passages made by the solenes, or rasor shells.

44. Callianassa. Genus XLIV. Callianassa. Antennæ placed in nearly the same horizontal line; the peduncle of the exterior with four joints, and a seta three times as long as the peduncle; the footstalk of the interior antennæ with three joints, and a jointed seta a little longer than the peduncle. A large scale attached to the base of the internal antennæ above. Abdomen with six membranaceous joints. Feet compressed; the two anterior pair compound, the third pair with a simple moveable thumb; hands of the anterior pair jointed; wrist entire. The middle process of the tail triangular, with the point very sharp.

Subterranea. *Sp.* 1. *Subterranea.* Thorax smooth and membranaceous, the anterior part crustaceous above. Claws unequal; the larger one very smooth, with the margin and fingers ornamented with tufts of hair; inner side of the thumb denticulated; wrist triangulated, with the margins toothed, armed at the base with a hooked process; arm angulated, denticulated beneath: smaller claw with oblong, oval, and somewhat hairy fingers, the arms and wrists being simple, and not angulated. The second pair of feet with hairy fingers, and an ovate hand; the third with a moveable thumb, very much compressed and ciliated; the fourth and fifth simple, with compressed hairy tarsy.

Cancer astacus subterraneus, Montagu, *Lin. Trans. Callianassa subterranea* of Leach's MSS.

This singular animal was discovered by Mr Montagu, whilst digging for *Solen vagina* in a sand bank in the estuary of Kingsbridge, on the south coast of Devon, about two feet beneath the surface. He informs us that they are rare, but that a sufficient number has been taken, to shew that the larger claw is not constant to one side. The females are very rare. Length about two inches.

Mus. Montagu, Sowerby, Leach, Prideaux.

45. Alphæus. Genus XLV. Alphæus. The exterior antennæ situated lower than those of the middle, with a large scale attached to the peduncle, (this scale being generally notched on the external side of the point.) The four anterior feet compound. Wrists of the second pair jointed. Middle process of the tail of an oblong-triangular shape, the apex much narrower than the base.

* The anterior larger than the second pair of feet.

Avarus. *Sp.* 1. *Avarus.* Hands unequal and difformed; rostrum short and subulated.

Alphæus avarus of Fabricius and Latreille.

** The second pair of feet larger than the first.

Crustacea.

Flavescens. *Sp.* 2. *Flavescens.* Body entirely yellow.

Alphæus flavescens of Latreille.

Marmoratus. *Sp.* 3. *Marmoratus.* Body pale rufous, mottled with red.

Alphæus marmoratus of Latreille.

This and the foregoing species inhabit the East Indian ocean, and are described by Latreille, from specimens in the French museum of natural history, and on his authority we introduce them here.

46. Penæus. Genus XLVI. Penæus. The exterior lower than the internal antennæ, with a scale attached to the peduncle, (often notched on the external side of the apex). The six anterior feet compound; the anterior pair shortest. Middle process of the tail-fin oblong-triangular, the apex much narrower than the base.

Monodon. *Sp.* 1. *Monodon.* Rostrum porrected, and turning upwards; serrated above, armed with three teeth below.

Penæus monodon of Fabricius and Latreille.

Observe. To this section another genus (not hitherto defined by any author) seems to belong, which contains *Cancer astacus gibbosus* of Montagu. *Lin. Trans.* vol. ix. pl. 5. fig. 1. But as we have never seen perfect specimens, we refrain from attempting a generic character, which must necessarily be very defective. We shall therefore describe the animal in Montagu's own words.

" Body slender, incurvated, with six joints. Thorax smooth. Proboscis long, laterally compressed, and serrated; a small spine on each side the proboscis, and another beneath each eye. Antennæ four; upper pair shortest and bifid; lower pair single, nearly as long as the body. Two anterior ciliated plates. Eyes pedunculated. Arms and legs scarcely definable; the anterior pair is terminated by a quadrifid joint; the second pair is cheliform, the other three pair appear when magnified to have a toothed claw. Besides these, there are two very long and slender appendages, which do not strictly appear to be legs, but seem to be auxiliary to the palpi, though they originate so far from the mouth, for they are always placed forwards towards the mouth; these are slightly chelate. The caudal fins are similar to those of the prawn, with a slight spine near the end of the exterior pair. Colour, when alive, red. Length about an inch. Not unfrequently taken by dredging at Torcross, Devonshire." See *Hippolyte* in the Index.

** Interior antennæ with three setæ.

47. Palæmon. Genus XLVII. Palæmon. Four anterior feet compound.

A. Anterior pair smaller than the second.

Squilla. *Sp.* 1. *Squilla.* The rostrum acute, and turning upwards; the superior part with seven teeth, longer than the peduncle of the internal antennæ.

Cancer squilla of Linné. *Astacus serratus* of Pennant. *Palæmon squilla* of Fabricius and Latreille.

Inhabits the European ocean, frequenting most of our shores, lurking amongst loose stones and algæ, in pools left by the tide, where it is taken by means of a small net fixed to a hoop. It is the common prawn of our markets. When alive, cinereous, elegantly banded with brown; but by boiling, it acquires a fine red colour. Pennant says, that it is frequently taken over thirty fathoms depth of water, but we have never observed it in such a situation. Length five inches.

Varians. *Sp.* 2. *Varians.* Rostrum straight, a little longer than the peduncle of the middle antennæ, with four teeth in the upper side.

Palæmon varians, Leach's MSS.

A very common species on the Devonshire and Glamorgan coasts, where it is taken and sold under the name of shrimp. It may possibly be *Astacus squilla* of Pennant, but the descriptions of that author are so laconic, that we are in great doubt in this as in various other instances. Length two inches and a half or three inches.

B. Anterior larger than the second pair of legs.

Sp. 3. *Nitescens.* Rostrum without teeth. Nitescens.

Cancer astacus nitescens of Montagu. *Athanas nitescens*, Leach's MSS.

Found on the southern coast of Devonshire by Col. Montagu. Length one inch, or rather less.

Division II. Hands without the finger, having only a moveable thumb.

Genus XLVIII. Crangon. Anterior pair of feet largest, and furnished with a moveable thumb; the other four pair unequal and simple. 48. Crangon.

Sp. 1. *Vulgaris.* Shell smooth, rostrum short, with a single groove above. See Plate CCXXI. Fig. 5. Vulgaris. Plate CCXXI. Fig. 5.

Cancer crangon of Linné. *Astacus crangon* of Pennant. *Crangon vulgaris* of Fabricius and Latreille.

Inhabits all the sandy shores of the European ocean; is the common shrimp of the English markets. Its colour when alive is cinereous, inclining to transparent, beautifully mottled and spotted with brown and blackish-brown.

Division III. All the feet simple, having neither finger or thumb.

Genus XLIX. Praunus. Legs on each side fourteen, set in a double series at the sides of the thorax. Female furnished with a pouch, situated at the base of the abdomen, in which she carries her young after their exclusion from the egg. 49. Praunus.

This genus was instituted by Mr Leach, who has derived the name from the English word *prawn*.

Sp. 1. *Flexuosus.* Middle process of the tail-fin deeply notched. Flexuosus.

Cancer flexuosus of Müller. *Cancer multipes* of Montagu. *Lin. Trans.* vol. ix. tab. 5. fig. 3. *Praunus flexuosus*, Leach's MSS.

Discovered as an inhabitant of Britain by Mr Henry Boys of Sandwich. It has since been observed by Mr Montagu on the south coast of Devon, and accurately described by him in the ninth vol. of the *Linnean Transactions.* As he never saw it alive, the following account, extracted from Mr Leach's MSS. may not prove uninteresting.

" Colour when alive pellucid-cinereous. Eyes black, red at their base. Laminæ of the head with a black longitudinal line, and spots. A clouded spot on each side the hinder part of the thorax, and another above the legs. Every segment of the body above beautifully marked with a reddish rust-coloured spot, disposed in an arborescent form; tail-fin spotted with the same colour, mixed with black. Pouch of the female with two rows of fuscous-black spots. Under side of the abdomen regularly mottled with rufous-black. It is found with fry from the middle of June to the middle of July. Females one-third more abundant than the males." Mr Leach observed them in great abundance in pools left by the tide in the Frith of Forth near Leith. Length an inch and a quarter."

Sp. 2. *Integer.* Middle process of the tail entire and not notched. Integer.

Praunus integer, Leach's MSS.

This species was discovered by Mr Leach at Loch-Ranza, Isle of Arran, in brackish pools left by the tide, in the month of August, in the greatest abundance. The females were with young, and the males were more abundant than the females. Like the foregoing species, it swims with its head uppermost, having a most grotesque appearance. Colour when alive, pellucid, cinereous, spotted with black and reddish-brown, varying much in their position. Mr Leach confesses, that he did not at first conceive it to be distinct from *Praunus flexuosus*, but on examination found that they not only differed in size, but most essentially in the middle process of the tail-fin. Length a third of an inch.

Family XII. Squillarii.

50. Squilla. Genus L. Squilla. Interior antennæ with three articulated setæ. Two large arms. Ten feet, with an hooked hand; the other six simple.

Mantis. *Sp.* 1. *Mantis.* Upper part of the body with several elevated longitudinal lines; thumbs with six dents.

Inhabits the Mediterranean and Asiatic seas.

Cancer mantis of Linné. *Astacus mantis* of Pennant? *Squilla mantis* of Fabricius and Latreille.

This species has been introduced into the *British Fauna*, but the authority is questionable.

51. Mysis. Genus LI. Mysis. Interior antennæ with two articulated setæ. Arms small. Twelve feet, all armed with a claw, and formed for swimming.

Saltatorius. *Sp.* 1. *Saltatorius.*

Cancer pedatus of Otho Fabricius. *Mysis saltatorius* of Latreille.

Inhabits the Greenland Sea.

This genus is introduced from the *Genera Insectorum et Crustaceorum* of Latreille, who owns that he has never examined the species himself, but has admitted it into his work solely on the authority of Otho Fabricius.

Family XIII. Gnathionii.

52. Gnathia. Genus LII. Gnathia. Mouth with two strong porrected mandibules or jaws, concave above, convex below. Antennæ setaceous; the upper pair rather longest. Feet ten, all armed with a nail. Tail jointed, and furnished with a swimming tail, as in the family Astacini.

Termitoides. *Sp.* 1. *Termitoides.* Mandibules on the inner side armed with minute teeth; middle process of the tail triangular, apex acute.

Cancer maxillaris of Montagu.

Gnathia termitoides, Leach's MSS.

Inhabits the British Ocean, but is not common.

Mr Leach suspects, that *Oniscus cœruleatus* of Montagu, *Lin. Trans.* vol. xi. is the female of this animal.

Family XIV. Gammarini.

1. Superior antennæ shorter than the peduncle of the inferior antennæ. Feet fourteen.

53. Talitrus. Genus LIII. Talitrus. Anterior pair of feet larger than the second pair; no hands.

Observe. The animals of this genus are familiarly known under the name of *sandhoppers*, and cannot have escaped the observation of the most cursory observer, multitudes being seen, during the summer, on all our sandy shores, skipping about in all directions in the evening. Their use in the economy of nature appears to be that of contributing to the dissolution of putrid animal and vegetable matter.

Locusta. *Sp.* 1. *Locusta.* Inferior antennæ as long as the body; the last division with between thirty and forty smaller joints.

Cancer locusta of Pennant and Gmelin. *Oniscus locusta* of Pallas. *Gammarus locusta* of Fabricius? *Cancer gammarus saltator* of Montagu. *Talitrus locusta* of Latreille.

Inhabits the sandy shores of the European ocean. It has acquired the name *Locusta* from the form of its mouth, which is protruded, and very much resembles that part of a locust. Length three quarters of an inch. Colour, when alive, corneous; when dead, whitish, and often mottled with reddish. It has never been taken in the water; it burrows in the sand, and serves as food to the shore birds, who devour it with avidity.

Sp. 2. *Littoralis.* Inferior antennæ much shorter than the body, the last segment composed of about twenty-five joints. Littoralis.

Talitrus littoralis. Leach's MSS.

Inhabits all the sandy shores of Britain. It was first observed by the Rev. J. Fleming, who communicated it to Mr Leach, from whose manuscripts it is here inserted. Length about half an inch. Colour corneous, inclining to reddish on the back. It is so common, that a more minute account is unnecessary, it having all the habits of the preceding species.

Genus LIV. Orchestia. Two anterior pair furnished with a moveable thumb, which is capable of being bent on the edge of the hand; second pair largest, having a compressed hand. 54. Orchestia.

Sp. 1. *Littorea.* Hand ovate, the part which meets the thumb slightly toothed or wrinkled. Thigh of the posterior pair of legs jointed, and very much compressed. The female wants the hands. See Plate CCXXI. Fig. 6. Littorea. Plate CCXXI. Fig. 6.

Pulex marinus of Baxter; *Cancer gammarus littoreus* of Montagu; *Orchestes littorea*, Leach's MSS.; *Talitrus gammarellus*, Latreille?

This species is the only one of the genus hitherto discovered. It is very common on many of our shores, lurking under the rejectamenta of the sea, having all the habits of the preceding genus. Latreille quotes Baxter's figure, which renders it highly probable that this may be his *Talitrus gammarellus*; but as he quotes also the *Oniscus gammarellus* of Pallas, it still remains in some doubt.

2. Superior antennæ longer, or at least as long as the inferior. Fourteen feet, the third and fourth pair smallest.

Genus LV. Gammarus. The four anterior feet furnished with a moveable nail, which is capable of being bent inwards on the hand. Abdomen with thirteen joints. Peduncle of the antennæ with three joints. 55. Gammarus.

Observation. The animals composing this genus inhabit ponds and rivulets, also the sea side. The males are considerably larger than the females, which they embrace with their claws, often swimming about with them, and not unfrequently on their back. The females carry about their young with them after their exclusion.

* Fresh water.

Sp. 1. *Pulex.* Eyes ovate, situated on a level with the base of the superior antennæ; back near the tail with fasciculi of spines. Pulex.

Cancer pulex of Linné and Pennant; *Gammarus pulex* of Fabricius and Latreille.

This species is utterly incapable of living in the sea, although we have the authority of Linné and many of his followers to the contrary; the truth is, that Linné included the various species of this genus under the names *Cancer locusta* and *Pulex*; this shows the necessity and advantage of constituting natural genera, the only way by which we can ever hope to attain an accurate knowledge of species.

A species which Mr Leach considers as distinct from *pulex*, was discovered in water taken from a

Crustacea. newly sunk well, in the square of St Bartholomew's hospital, London, by Thomas Wheeler, Esq. apothecary to that institution, who sent it to Mr Leach, in whose collection it is now preserved. It is very probably a young animal; it differs principally from *Gammarus pulex*, in having the upper process of the tail much longer. The colour, when alive, was cinereous, but so translucent, that the eyes could not be discovered; it stands in Mr Leach's cabinet, under the specific name *subterraneus*, as it most probably inhabits springs under the earth.

** Marine.

Locusta. *Sp.* 2. *Locusta.* Eyes lunated and placed in a line with the superior antennæ; back near the tail with fasciculi of spines.

Cancer locusta of Linné. Is it *Cancer gammarus locusta* of Montagu? *Linn. Trans.* vol. ix.

Inhabits pools left by the tide, on all the rocky shores of Great Britain.

Length of the male an inch.

Camylops. *Sp.* 3. *Camylops.* Eyes shaped like the capital letter S, extending from the upper part of the superior to the upper part of the base of the inferior antennæ. Back near the tail with fasciculi of spines.

Discovered on the shore of Arran, by Mr Leach, who named it, from the flexuous shape of the eyes, *G. camylops.*

Length of the male half an inch, female somewhat less.

Mus. Leach

Rubricatus. *Sp.* 4. *Rubricatus.* Eyes angulated; situated between the superior and inferior antennæ.

Cancer gammarus rubricatus of Montagu. *Ampithöe rubricata*, Leach's MSS.

Length half an inch.

Inhabits Britain.

Discovered by George Montagu, Esq. and well described by him in the *Transactions of the Linnean Society*, vol. ix. Colour, when alive, usually reddish, or pale pink, minutely and closely speckled with spots of a darker shade. Eyes crimson. It is a rare species, and possibly does not belong to this genus.

56. Mæra. Genus LVI. Mæra. Anterior pair of feet with a moveable nail; the second pair with a compressed hand and moveable thumb. Peduncle of the antennæ with three joints; the superior antennæ longest.

Grossimana. *Sp.* 1. *Grossimana.* Body smooth, with eleven joints; superior antennæ nearly as long as the body. Internal edge of the palm of the second pair of feet ciliated, having a slight groove to receive the thumb.

Length five lines.

Colour, when alive, pale yellow, sometimes mottled with pink.

Cancer gammarus grossimanus of Montagu. *Mæra grossimana.* Leach's MSS.

Inhabits pools left by the receding tide, on all our rocky shores.

57. Melita. Genus LVII. Melita. Anterior pair of feet very small; second pair with a compressed hand, and moveable nail which bends on the palm. Superior styles of the tail very long and large.

Palmata. *Sp.* 1. *Palmata.* Blackish; the tail above, with a few spines.

Inhabits the rocky shores near Plymouth in Devonshire. Crustacea.

Gammarus palmata, Montagu, *Linnean Transactions*, vol. vii. tab. 6. *Melita palmata*, Leach's MSS.

Genus LVIII. Leucothöe. Anterior feet with a finger and thumb; the thumb jointed; second pair with a moveable thumb but no finger. Peduncle of the antennæ with two joints. Superior antennæ longest. 58. Leucothöe.

Sp. 1. *Articulosa.* Body smooth and glossy. Eyes garnet-coloured. Wrist of the second pair of feet with a projecting compressed lamella. Internal edge of the hand slightly toothed. Articulosa.

Cancer articulosus of Montagu.

Leucothöe articulosa. Leach's MSS.

Inhabits the bottom of the sea.

Length half an inch.

Mus. Montagu, Leach.

Obs. It is probable that *Phronima sedentaria* of Latreille, *Genera Crustaceorum et Insectorum*, vol. i. p. 56. plate 2. fig. 2. forms a distinct family; but as a specimen has never come under our inspection, we shall translate his words in this note.—" Feet ten; the third pair longest and furnished with compound hands.

" *Cancer sedentarius Forsk. F. Arab.* page 95."

He observes farther, that it inhabits the Mediterranean Sea, dwelling in a cell composed of a gelatinous matter, (perhaps the dead body of a beroe,) of a bladder-like appearance, open at both ends. It often changes its posture, but generally sits within its nest.

It has lately been discovered in Zetland amongst the rejectamenta of the sea, by the Rev. J. Fleming, one of our most zealous and enlightened naturalists.

Family XV. Corophini.

Genus LIX. Corophium. Body elongated, composed of ten joints. Tail three jointed, with four bifid styles. Feet fourteen, the anterior pair furnished with a moveable thumb. The upper antennæ armed with a seta, the under ones as long as the body, very thick, more resembling feet than antennæ. 59. Corophium.

Sp. 1. *Longicornes.* The under part of the second joint of the antennæ near the apex, armed with a sharp spine. Longicornes.

Cancer grossipes of Linné; *Oniscus volutator* of Pallas; *Gammarus longicornis* of Fabricius; *Astacus linearis* of Pennant; and *Corophium longicorne* of Latreille.

Inhabits the European Ocean.

Length half an inch.

Family XVI. Caprellini.*

Genus LX. Caprella. Body linear. Eyes situated behind the antennæ. Antennæ four jointed, the upper ones with the last segment as long as the three others, and composed of several minute articulations; the under ones somewhat compressed, half the length of the superior. The first pair of feet (*palpi* of Montagu) situated very near the mouth; the second pair with the hand denticulated on the inside. Fins of a membranaceous jelly-like substance of a globular form. The anus with two little appendices. 60. Caprella.

* The body of these animals, exclusive of the head, is composed of six joints, all except the second and third bearing feet. The second and third segments furnished on each side with two processes, which probably serve as fins. Feet ten, all armed with a moveable nail; the anterior pair very small, and originating from the head. Mouth with two jointed palpi, armed at the point with a little hook.

The female is furnished with a pouch; situated between the fins, in which she carries about the eggs and her young after their exclusion, until they are enabled to shift for themselves.

Crustacea.

Linearis.

Sp. 1. *Linearis.* Head with one little tubercle. Hand of the second pair of feet with three teeth on the inner edge.

Cancer linearis of Linné; *Astacus atomos* of Pennant; *Caprella linearis* of Latreille; *Oniseus scolopendrioides* of Pallas.

Inhabits the European Ocean, affixing itself to fuci and other marine plants. Colour, when alive, brown, inclining to cinereous, beautifully spotted with rust-colour.

Phasma.

Sp. 2. *Phasma.* The first joint of the body with two spines; a third spine on the anterior part of the second joint; a fourth spine on the head, all pointing forward. Hands of the second pair of feet with one strong spine. Colour generally pale olive green. Discovered on the coast of South Devon on *fuci*, by Mr Montagu, and described in vol. vii. of *Linnean Transactions*, by him.

Penantis.

Sp. 3. *Penantis.* Back without spines; anterior part of the head produced into a spine; hands of the second pair of feet with one tooth.

Astacus atomos of Pennant.

Common on the Devonshire coast.

Acanthifera.

Sp. 4. *Acanthifera.* Back, especially the hinder part, spiny; inner edge of the second hands lunate-excavated.

Caprella acanthifera, Leach's MSS.

Discovered in Devonshire, where it is not uncommon.

61. Panope.

Genus LXI. Panope. Body depressed. Eyes situated on the vertex of the head. Antennæ four jointed; the upper pair, with the basilar joint, largest; the second and third equal, but rather shorter than the first; apical joint very small; inferior pair also composed of four joints, shorter than the first joint of the upper pair. Feet compressed and armed with strong nails; the anterior pair situated on the base of the head, the wrist jointed. Hands of the second pair armed with teeth on their inner edge. Fins of a leathery-membranaceous substance, cylindrical and elongated. Anus produced, having a few obscure small tubercles on each side and under.

The pouch of the female with four valves.

Ceti.

Sp. 1. *Ceti.* Base of the fins with a process resembling the figure 6; the hands of the second pair of feet with two obtuse teeth on the thumb side of the hands. Anus with three processes.

Inhabits the European Ocean, attaching itself to whales, and, according to Latreille, to fishes of the genus Scomber.

Oniscus ceti of Linné; *Pycnogonum ceti* of Fabricius. *Panope ceti*, Leach's MSS.

Family XVII. Apseudii.

62. Apseudes.

Genus LXII. Apseudes. Body six jointed, tail with six segments, the last largest, armed at the apex with appendices. Feet fourteen, the *anterior pair* with a finger and thumb; the *second pair* compressed and dentated; the *third and fourth* alike and simple; the *fifth* with a double nail?; the *sixth and seventh* spurious. The superior antennæ with a biarticulated peduncle armed at the apex with a jointed seta; the inferior antennæ bifurcate.

Talpa.

Sp. 1. *Talpa.* Rostrum acute, with three excavated longitudinal grooves.

Cancer gammarus talpa of Montagu; *Apseudes talpa*, Leach's MSS.

Inhabits the British Ocean; length four lines; colour yellowish-white; is very rare.

Mus. Montagu, Leach.

ORDER III. MYRIAPODA.

Crustacea.

Family XVIII. Asellides.

I. The four antennæ very distinct.

Genus LXIII. Asellus. Tail composed of one piece, with two longitudinal foliaceous double-jointed lamellæ, and two bifid styles inserted about the middle of the posterior margin. Antennæ setaceous; the last segment composed of a great many smaller joints. 63. Asellus.

Sp. 1. *Vulgaris.* Colour cinereous, often spotted with grey or white. Vulgaris.

Inhabits ditches and wells very frequent, and is considered as a proof of the goodness and purity of the water.

Oniscus aquaticus of Linné and Donovan; *Idotea aquatica* of Fabricius; *Entomon hieroglyphicum* of Klein; *Asellus vulgaris* of Latreille.

Genus LXIV. Idotea. Tail with two or three segments, and two longitudinal plates as in the genus Asellus. The internal or middle antennæ composed of four joints, and placed somewhat above the exterior ones. 64. Idotea.

Genus Stenosoma of Leach.

* Body linear, external antennæ very long.

Sp. 1. *Hecticus.* The segments of the abdomen laterally dilated. Colour cinereous brown, or greenish-brown, sometimes bordered with grey or cinereous brown. Hecticus.

Inhabits the European Ocean.

Oniscus linearis of Pallas and Pennant; *Oniscus hecticus* of Gmelin. *Idotea tridentata* of Latreille is only a variety of this species.

** Body thickest in the middle. Idotea, Leach.

Sp. 2. *Entomon.* Body of an oblong oval; the segments swelling at the sides; tail conical and elongated, having a tooth on each side of the base. See Plate CCXXI. Fig. 7. Entomon. Plate CCXXI. Fig. 7.

Inhabits the European Ocean.

Oniscus entomon of Linné and Pennant; *Cymothoa entomon* of Fabricius; *Oniscus œstrum*, Donovan, in Rees' *Cyclopædia*, article Entomology, plate x.

It is very probable that *Oniscus marinus* of Pennant is merely a variety of this species; both are found on all our rocky coasts in the greatest plenty: it differs merely in having the tail more conical than in *entomon*, and having no teeth at the base; there are, however, so many intermediate varieties, that it cannot with propriety be considered as a distinct species.

Sp. 3. *Œstrum.* Segments of the abdomen slightly prominent at the sides. Tail deeply notched, with a very small protuberance in the middle of the notch. Œstrum.

Inhabits the European Ocean.

Oniscus œstrum of Pennant.

Genus LXV. Anthura. Body linear; tail with two broad moveable plates on each side, which, when the animal is alive, much resemble a five-petaled flower. Antennæ short, the interior or upper pair rather longest. Anterior pair of feet furnished with a moveable hook or thumb. 65. Anthura.

Sp. 1. *Gracilis.* Lateral appendices of the tail obliquely truncated. Colour pale, coloured with rufous. Gracilis.

Inhabits the British seas, but is very rare.

Oniscus gracilis, Montagu; *Anthura gracilis*, Leach's MSS.

Observation. *Oniscus cylindricus* of Montagu, *Linnean Transactions*, vol. vii. p. 71. plate 6. fig. 8, seems to belong to a genus nearly allied to *Anthura*; but as no specimen has ever occurred to us, we must content ourselves with transcribing the description given by that author.

" *Oniscus cylindricus*, with a smooth, glossy, cylindric, and very convex body, with seven joints independent of the head, tail, and five narrow segments at the base of the latter; central caudal fin subovate, with two smaller lateral ones on each side, which, when spread, give it a quinquedentate appearance: antennæ four, short, the upper pair not half so long as the other; legs fourteen; feet of the foremost six broad, serrated on the inside; all armed with a single claw.

"Length an inch; breadth not quite a quarter. Colour pale yellow, clouded with cinereous on the sides."

66. CYMOTHOA. GENUS LXVI. CYMOTHOA. Tail composed of a great many segments, the last at its base bearing a double appendage on each side. Most of the segments bearing feet, their lateral margins being thickened. Antennæ setaceous and many-jointed, inserted one pair above the other, under the clypeus. Feet with strong, sharp nails.

Asilus. *Sp.* 1. *Asilus.* Head with three protuberances or lobes on the hinder part: the hinder segments (the last excepted) arched backwards; the last segment semi-elliptical.

Inhabits the European ocean.

Oniscus asilus of Linné and Pallas; *Cymothoa asilus* of Fabricius and Latreille.

Œstrum. *Sp.* 2. *Œstrum.* Body oblong oval, the last segment transverse.

Inhabits the European Ocean.

Oniscus œstrum of Linné and Pallas; *Cymothoa œstrum* of Fabricius and Latreille.

Observation. It is highly probable that *Oniscus testudo* of Montagu (*Transactions of the Linnean Society of London*, vol. ix. page 102. tab. 5. fig. 5.) is referable to a genus akin to this; but as we have never had an opportunity of examining this species, we cannot speak with certainty on this head, but content ourselves by quoting the description given by that author.

"*Oniscus testudo.* Body subovate, composed of eight joints, rising to a ridge on the back; the plates elevated on their edges; the four first fall very low on the sides, and obscure the anterior legs; along each side of the body a row of small tubercles: the front sub-bifid: antennæ four, very short, the lower pair hid beneath: eyes prominent and black; posterior end obtusely pointed; caudal fins beneath, obscure; legs fourteen, short and strong, the three posterior pairs longest; all furnished with a simple claw.

"Length two lines.

"Colour dull red, with a white spot on the anterior part of the back, but as the animal dies this mark is lost. Rare."

67. SPHÆROMA. GENUS LXVII. SPHÆROMA. Tail composed of two segments; the last furnished with a double lateral foliaceous appendage, placed on a common footstalk on each side. Body oval, capable of rolling into a globular form, composed of seven joints. Antennæ setaceous and many jointed, inserted by pairs one above the other; their bases placed very close together; the upper pair with a very large peduncle.

Serrata. *Sp.* 1. *Serrata.* Body smooth; the anal segment of the tail rounded, the sides obliquely truncated; the lamellæ equal, elliptical, with their points sharp.

Oniscus globator of Pallas; *Cymothoa serrata* of Fabricius; *Sphæroma cinerea* of Latreille.

Inhabits the European Ocean; is very abundant on several of our rocky coasts in pools left by the tide; when touched, it contracts into a ball. Length nearly half an inch. Colour, when alive, cinereous, very beautifully speckled with black.

Rugicauda. *Sp.* 2. *Rugicauda.* Body smooth; the anal segment rough, rounded at the apex; the sides obliquely truncated; the lamellæ equal, their points somewhat rounded.

Sphæroma rugicauda, Leach's MSS.

Inhabits the Atlantic Ocean.

It was discovered on the shore of Ulva, one of the Western Isles of Scotland, by Mr Leach: he observed that it was more agile than *Sphæroma cinerea*, from which species it is readily distinguished by the roughness of the anal segment, and the smaller size of the peduncle of the superior antennæ. He has since observed it in very great plenty near the Ware-head, on the river Tamer, in Devon, where the water is but brackish; a curious contrast with the original habitat in the Atlantic!

Colour, when alive, cinereous, very beautifully speckled and streaked with black. Eyes black. Length about one-third of an inch.

GENUS LXVIII. NESÆA. Apex of the tail on each side with a single foliaceous appendage placed on a footstalk. Body oblong. Antennæ setaceous, and nearly of an equal length; the upper pair with a very large double-jointed peduncle, (the basilar joint largest,) which occupies nearly half their length. Space between the antennæ very visible. Body composed of six joints, the last largest. 68. NESÆA.

Sp. 1. *Bidentata.* Last segment of the body armed with two spines or teeth. Bidentata.

Oniscus bidentatu, Linnean Transactions.

Næsea bidentatas, Leach's MSS.

Inhabits the British ocean: the living specimens we have seen were cinereous, faintly streaked with red.

GENUS LXIX. CAMPECOPEA. Base of the tail armed with a bent foliaceous process on each side. Body composed of six joints. Antennæ setaceous, the upper pair longest, with the peduncle composed of two visible joints; the intermediate space between the superior antennæ very great. 69. CAMPECOPEA.

Sp. 1. *Hirsuta.* Body hirsute. Hirsuta.

Oniscus hirsutus, Montagu, *Lin. Trans.* vol. vii. t. 6. f. 8. *Campecopea hirsuta*, Leach's MSS.

Colour (according to Montagu) brown, with sometimes a few faint bluish spots on the posterior joint. Length one-eighth of an inch.

Inhabits the European ocean, but is rather rare.

II. The antennæ obscure, or entirely wanting.

GENUS LXX. BOPYRUS. Body depressed, of an incurvate oval form. The under part on each side with four foliaceous marginal appendices. Feet minute, spurious, bent, and placed on the margin. The last segment of the tail small. 70. BOPYRUS.

Sp. 1. *Squillarum.* Colour pale greenish. Squillarum.

Monoculus crangorum of Fabricius. *Bopyre des crustacés* of Bosc. *Oniscus squillarum* of Montagu. *Bopyrus squillarum* of Latreille.

Inhabits the European ocean, dwelling under the thoracic plate of the prawn (*Palæmon squilla*) or shrimp (*Crangon vulgaris*), and causing a tumour on the sides of the animal. It varies much in shape, taking the form of the shell. It is so common, that it is surprizing it should have escaped the notice of all British naturalists until it was described in the ninth volume of the *Linnean Transactions*, by George Montagu, Esq. It was first described in the *Memoirs of the Academy of Sciences*, in the year 1772, page 29, pl. 1.

Observation. Mr Montagu has described an animal as inhabiting the thoracic plate of CALLIANASSA *subterranea*; and as we have never seen the species, we

Crustacea.

must content ourselves by extracting the description given by that celebrated zoologist.

" *Oniscus thoracicus.* Body oval, inequilateral, with about fifteen indistinct joints, indented at the sides, the six posterior shooting into long, lateral, fasciculate, fleshy, ramose appendages, and the extremity furnished with six simple recurved ones, two of which are larger than the rest. Antennæ four, short; the outer pair longest, and only visible above. The two first joints of the body furnished with a long, flat, oar-like, fleshy fin, or cirrus, on each side; the other joints with similar short ones. Legs fourteen, very short, crooked, and concealed beneath. The abdominal valves are large, cover the whole under part of the body, and form a receptacle for the ova, which are, in specimens before me, vastly distended with many thousands of a pale orange colour.

" Length, including the posterior appendages, scarcely half an inch.

" Colour usually orange; lateral appendices whitish.

" The male is very inferior in size, of a more slender form, and is destitute of the cirri on the anterior part of the body, and those on the posterior joints are simple, not branched, as in the female; in other respects they agree."

Mr Montagu says likewise that he has extracted it from under the thoracic plate, and kept it alive in a glass of sea-water for several days. In the few which he has met with, the male was always found attaching itself to the ventral appendices of the female by its claws. That it forms a distinct genus from any here defined, and is referable to another division of the tribe, need scarcely be mentioned to the scientific reader.

Family XIX. Oniscides.

71. Ligia.

Genus LXXI. Ligia. The outermost segment of the external antennæ composed of a number of small articulations. A bifid style, placed on a peduncle on each side of the tail.

Observation. It has been supposed by Latreille, and other authors of eminence, that the number of joints in the last section of the external antennæ afforded specific distinctions in this genus; the observations, however, which we have made on *L. oceanica* and *scopulorum*, fully prove the evanescence of this character, as the joints not only vary in number in the same species, but even in the same individual.

Oceanica. Plate CCXXI. Fig. 8.

Sp. 1. *Oceanica.* Body brownish; back very rough; sides often beautifully speckled with minute black spots. See Plate CCXXI. Fig. 8.

Oniscus oceanicus, Linné. *Ligia oceanica* of Fabricius and Latreille.

Length half an inch.

Inhabits the shores of the European ocean.

This, and probably all the species, are very prolific: Mr Williams, an ardent student of zoology, found above seventy young ones in the abdominal pouch of a female, in the month of August.

Scopulorum.

Sp. 2. *Scopulorum.* Body cinereous, sides speckled with minute black spots; back somewhat rough.

Ligia oceanica, variety, Leach's MSS.

This species, which is probably a variety of the preceding, is very common on the rocky coasts of Devonshire. It is nearly three times the size of *L. oceanica,* from which it is readily distinguished by the comparative smoothness of its back, and superior size.

Observation. The above species are all that we have met with. Three others are enumerated by Latreille; these we shall mention in his words.

" 3. *Italica.* Antennæ almost as long as the body; the last joint composed of seventeen minute articulations; styles of the tail equal, exserted; the footstalks narrow and elongated." Italica.

Ligia Italica of Fabricius.

4. " *Hypnorum.* Antennæ half the length of the body; the last joint composed of ten minute articulations; the caudal styles exserted, with the point of the peduncle internally produced into a setigerous tooth; the body above variegated with cinereous and yellow." Hypnorum.

Oniscus hypnorum of Cuvier and Fabricius.

Oniscus agilis of Panzer.

Latreille observes, " It inhabits the shores of the British Ocean; I received it from the celebrated Brébisson."

" 5. *Oniscoides.* Styles of the tail very short, not exserted; the laciniæ ovate-lanceolate." Oniscoides.

Oniscus assimilis of Linné. *Cymothoa assimilis* of Fabricius.

" Inhabits the Mediterranean Sea."

Genus LXXII. Philoscia. External antennæ eight-jointed, the base naked. The first segments of the tail abruptly narrower than the preceding joints of the body. 72. Philoscia.

Sp. 1. *Muscorum.* Body variegated with cinereous and white. Muscorum.

Oniscus muscorum of Scopoli and Cuvier. *Oniscus sylvestris* of Fabricius. *Philoscia muscorum* of Latreille.

Is found under mosses and stones in England, France, and Germany.

Genus LXXIII. Oniscus. The external antennæ with eight joints, inserted under the margin of the anterior part of the head. 73. Oniscus.

Sp. 1. *Asellus.* Body above obscurely cinereous and rough, with white longitudinal lines of spots; the sides yellowish. Asellus.

Oniscus asellus of Linné and Latreille. *Oniscus murarius* of Fabricius and Cuvier.

Inhabits rotten wood, old walls, &c. throughout Europe.

It was formerly used in medicine, being supposed to cure agues, consumptions, &c. but is now wisely rejected from the modern pharmacopœias. Its vulgar names are *common millepied* or *sows.*

Genus LXXIV. Porcellio. External antennæ seven jointed, inserted under the margin of the anterior part of the head. The lateral styles of the tail conic and prominent. 74. Porcellio.

Sp. 1. *Scaber.* Body above rough and granulated. Scaber.

Oniscus asellus of Cuvier, Fabricius, and Panzer; *Porcellio scaber* of Latreille.

Inhabits Europe.

This species is found under stones, in rotten wood, and on old walls. It varies much in colour, being at one time bluish black, at another time yellow. In Scotland it is called *sclater.*

Sp. 2. *Lævis.* Body smooth. Lævis.

Porcellio lævis of Latreille.

Inhabits the same place as the former species. In this country it is rare, one specimen only having been taken by Mr W. E. Leach, in Devon.

Obs. To this genus, *Oniscus convexus* of De Geer (*Mem. sur les Insect,* tom. vii. pl. 35. fig. 11.) appears to belong.

Genus LXXV. Armadillo. External antennæ seven jointed, the lateral styles of the tail not prominent, the last joint triangular, and meeting the hinder margin of the posterior margin. Body capable of rolling into a ball. 75. Armadillo.

Sp. 1. *Vulgaris.* Body above of a greyish-lead colour; the posterior margins of the segments white. Vulgaris.

Crustacea.

Oniscus armadillo of Linné and Cuvier; *Armadillo vulgaris* of Latreille.

Inhabits the roots of trees and rocks all over Europe.

Oniscus cinereus of Panzer is merely a variety of this species.

Its vulgar name is *Pill millepied.*

Variegatus. *Sp.* 2. *Variegatus.* Segments black, margined with white; back variegated.

Oniscus variegatus of Villers, *Armadillo variegatus* of Latreille.

Oniscus pulchellus of Panzer, (*Fn. Ins. Germ.* fasc. 62. fig. 21.) seems near akin to this species.

FAMILY XX. JULIDES.

76. GLOMERIS. GENUS LXXVI. GLOMERIS. Antennæ inserted on the upper anterior margin of the head; the two basilar joints small; the sixth, including the last, very large. Body oblong-oval, convex above, arched beneath, capable of contracting into a ball; the first segment very narrow, being merely a semicircular lamella; the second larger than any of the others; the last semicircular.

* *Feet on each side sixteen.*

Marginata. *Sp.* 1. *Marginata.* Body black above, the margins of the segments of a dirty orange yellow.

Inhabits Britain, France, and Germany, under stones.

Oniscus marginatus of Villers, *Oniscus zonatus* of Panzer, *Cloporte bordé* of Olivier, *Glomeris limbata* of Latreille, *Julus oniscoides* of Stewart.

Pustulata. *Sp.* 2. *Pustulata.* Body black above, spotted with red.

Inhabits the southern parts of France and Germany.

Oniscus pustulatus of Fabricius; *Oniscus armadillo* of Scopoli.

** *Feet on each side twenty.*

CRYXUS, Leach's MSS.

Ovalis. *Sp.* 3. *Ovalis.* Body dirty yellow.

Inhabits the ocean.

Julus ovalis of Linné, *Julus ovatus* of Fabricius, *Glomeris ovalis* of Latreille, CRYXUS *ovatus*, Leach's MSS.

It is surprising that Latreille should have placed this species in the genus GLOMERIS: though we had never seen the animal, the description and figures would almost have justified us for entertaining this opinion; its economy, the number of legs, at once exclude it altogether from this genus; which, in Mr Leach's manuscripts, as above quoted, is considered as a distinct genus.

77. JULUS. Plate CCXXI. Fig. 9. GENUS LXXVII. JULUS. Antennæ inserted in the anterior margin of the head; the second joint longer; the sixth, including the seventh, (which is very minute), shorter than that which precedes it. Body cylindrical, elongate, serpentiform, the segments rarely marginated. Eyes distinct and granulated. (The second and third segments of the body often bearing but one pair of feet.) See Plate CCXXI. Fig. 9.

* Body not marginated or laterally depressed.

Terrestris. *Sp.* 1. *Terrestris.* Feet 64 to 74 pairs; back cinereous, with light brown annuli; the last segment pointed. *Latr. Gen. Crust. et Ins.* tom. i. p. 75.

Inhabits Europe.

Julus terrestris of Latreille, who describes it as having 64 or 74 pair of legs; Linné, Fabricius, and Degeer, mention 100 pair of legs as proper to this species. We have never seen this animal, therefore can give no opinion on this point; although it is probable, from the above remark, that two species have been confounded; future observation must however decide this point.

Niger. *Sp.* 2. *Niger.* Body black, legs pale, from 88 to 95 in number, (or perhaps more); the hinder part of the segment longitudinally streaked; anus pointed.

Inhabits Britain, under the bark of decaying trees, or under stones and moss.

Julus niger, Leach's MSS.

This species, when alive, is black, although it sometimes, though rarely, occurs of a brownish black colour. After death it generally changes to blue, having the margins of the segments brown or yellowish, with a row of black spots along the sides of the body. It is by far the most common species in the neighbourhood of Edinburgh.

Sabulosus. *Sp.* 3. *Sabulosus.* Back greyish-black, with two longitudinal reddish lines; the last segment pointed. Feet 95 pair.

Inhabits Europe; is common in this country under stones, and on the bark of trees.

Julus sabulosus of Linné, Fabricius, and Latreille.

Maximus. *Sp.* 4. *Maximus.* Feet on each side one hundred and thirty-four.

Inhabits America.

Julus maximus of Linné and Fabricius.

Fuscus. *Sp.* 5. *Fuscus.* Feet on each side one hundred and twenty-four; back brownish.

Inhabits India.

Julus fuscus of Linné and Fabricius.

Indus. *Sp.* 6. *Indus.* Feet on each side one hundred and fifteen; body rust coloured, the last segment pointed; feet yellowish.

Inhabits India.

Julus Indus of Linné and Fabricius.

Obs. There are several species, or varieties of Juli, belonging to this subdivision, which inhabit this country, but the marks by which they are distinguished are not sufficiently known to enable us to give an account of them. Much remains to be done in this department, and it would prove highly beneficial to science, were naturalists to breed, from the young state, the various species of these JULI, and mark the changes produced in the animal during its growth, as colour, formation of new feet, &c. Until this has been done, nothing can be added to this genus without great uncertainty.

** Body more or less marginated, or laterally compressed. Genus CRASPEDOSOMA of Leach.

Raulinsii. *Sp.* 7. *Raulinsii.* Body blackish; back with two light red longitudinal lines; head black; feet and belly reddish-white; side somewhat marginated, or rather compressed; back with one longitudinal sulcus.

Inhabits Scotland, under stones and in decaying trees.

Craspedosoma Raulinsii. Leach's MSS.

Discovered by a very assiduous entomologist, Richard Rawlins, Esq.* under stones near Edinburgh, where it appears to be pretty common; it has since been observed under the bark of decaying willow trees and moss, near Roslin and in Ravelston wood.

Polydesmoides. *Sp.* 8. *Polydesmoides.* Body considerably depressed;

* We have now most sincerely to lament the premature death of this gentleman, who, had he survived, would have proved one of the greatest ornaments in the department of Zoology including the animals without vertebræ that has ever appeared in this country. His industry and acquirements were truly astonishing, and his zealous ardour remained to his last moments.

Crustacea. the segments laterally produced, bearing little spines; back with one longitudinal groove; each segment with two slight tubercles on the sides of the groove.

Julus polydesmoides, Montagu's MSS.

Inhabits Devonshire, often occurring under stones.

78 Polydesmus. Genus LXXVIII. Polydesmus. Antennæ inserted on the superior margin of the head, the last joint exserted: body linear; the segments laterally compressed and marginated; eyes obsolete. *The seventh segment from the head bearing but one pair of feet in the male.* The anterior joints of the body, in both sexes, generally having but one pair of feet.

Complanatus. *Sp.* 1. *Complanatus.* Back tuberculated; body depressed; the last joint pointed; feet and belly light yellowish white; upper part light reddish-brown.

Julus complanatus of Linné and Fabricius; *Jule aplatie* of De Geer, *Polydesmus complanatus* of Latreille.

Inhabits moist woods and hedges under moss and stones; is very frequent about Edinburgh and London.

79. Pollyxenus. Genus LXXIX. Pollyxenus. Antennæ inserted under the margin of the head, very short and cylindrical. Body elongated and depressed, the last segment armed with a pencil.

Lagurus. *Sp.* 1. *Lagurus.* Body brownish.

Scolopendra lagura of Linné and Fabricius, *Pollyxenus lagurus* of Latreille.

Inhabits Europe. Not yet observed in Britain.

Family XXI. Scolopendrides.

I. Every segment of the body bearing two pair of feet.

80. Scutegera. Genus LXXX. Scutegera. Each joint bearing two pair of feet.

Coleoptrata. *Sp.* 1. *Coleoptrata.* Feet thirty; body reddish-yellow, with longitudinal lines, and bands on the feet of a blue-black colour.

Genus Cermatia of Illiger.

Julus araneöides of Pallas, *Scutigera araneöides* of Latreille.

Inhabits houses in the southern parts of Europe; In Mr Leach's museum are specimens of a very large size from Madeira.

II. Every segment of the body bearing one pair of feet.

The insects composing this division, have been considered, by all authors who have illustrated this department with their writings, as forming one genus, which they named Scolopendra. The specific characters were taken from the number of feet: thus all the species having forty-two feet, were considered as one species, under the name Scolopendra *morsitans*; and other species (as we shall point out below) were confounded with one another in the same manner. In the following arrangements, we shall adopt genera divided from Scolopendra by Mr W. E. Leach, which we have copied from his manuscripts.

81. Scolopendra. Plate CCXXI. Fig. 10. Genus LXXXI. Scolopendra. Antennæ conico-setaceous, composed of many articulations, which are nearly conical. The inferior lip somewhat narrower before than behind; the anterior margin denticulated, and divided by a deep fissure. Feet forty-two in number, the hinder pair spinous at their base. The segments of the body somewhat marginated. The anterior pair of feet minute. Eyes eight in number, four on each side placed in a rhomboidal form. See Plate CCXXI. Fig. 10.

Obs. All the species of this genus have been considered as one by all authors, their characters being "Pedibus utrinque 20, oculis octo," *Linn. Syst. Nat.* 1068. *Fab. Ent. Syst.* 2—390. In this character the last feet are not enumerated. In the works of De Geer and Latreille, we find the last pair (which are much larger than the rest, but organised in the same manner) computed as feet, and the character "posterioribus spinosis," particularly noted in the specific character: this last, as we have mentioned in the generic character, is common to all the species, as is also the Linnean "eyes eight." We shall now point one such species as have come under our notice; and we have no doubt that many more remain to be discovered, which hitherto have been confounded under the title of *S. morsitans.*

* The segments transversely quadrate.

Sp. 1. *Spinipes.* The segments rusty-brown; the angles rounded; the antennæ, palpi, galeæ, posterior margins of the segments, and feet, yellowish; all the feet (excepting the anterior pair) with small spines on their joints. Spinipes.

Scolopendra Spinipes. Leach's MSS.

Habitat unknown.

Described from a specimen preserved in the College Museum of Edinburgh. Length about 11 inches. The lip and base of the mandibulæ ferrugineous. The whole body, when examined with a lens, punctulated. The nails, heels, and apex of mandibulæ, pitchy black.

Sp. 2. *Inermis.* Segments brown, with the posterior margins and feet pale; feet not spiny; hinder feet, as in the generic character, spiny at their base. Inermis.

Mus. Dr Barclay.

Scolopendra inermis. Leach's MSS.

Habitat unknown.

** Segments oblong-square.

Sp. 3. *Morsitans.* Joints rust-brown coloured; feet pale. Morsitans.

Habitat unknown.

Mus. Dr Barclay.

Scolopendra morsitans. Leach's MSS.

*** Segments alternately oblong and transversely quadrate.

Sp. 4. *Inæqualis.* Segments rusty-brown; feet pale. Inæqualis.

Habitat unknown.

Scolopendra inæqualis. Leach's MSS.

Genus LXXXII. Cryptops. Antennæ conico-setaceous, with 17 globular sub-conical joints. Anterior margin of the lip not denticulated, and scarcely notched. The basilar joint of the posterior feet not spiny; legs forty-two; eyes not discernible. 82. Cryptops.

Sp. 1. *Hortensis.* Body testaceous, inclining to rusty-brown; the back darker in colour; antennæ and feet hairy. Hortensis.

Cryptops hortensis. Leach's MSS. *Scolopendra hortensis*, Donovan's *British Insects*, vol. xv. where it was first figured and described, from specimens sent by Mr Leach, under that name, to Mr Donovan.

Inhabits gardens in and near Exeter in Devonshire, discovered by Mr Leach.

Genus LXXXIII. Lithobius. Antennæ with many joints, (about 45) the two basilar ones largest, of a conical-filiform shape each, joints nearly conical. Eyes granulated. Inferior lip anteriorly notched, the margin much denticulated. Feet thirty. 83. Lithobius.

To this genus Scolopendra *coleoptrata* of Panzer is referable. Leach's MSS. translated.

Sp. 1. *Forficatus.* The whole under lip deeply punctulated, the dots impressed; feet testaceous-yellow. Forficatus.

Scolopendra forficata of Linné, Fabricius, and Latreille; Lithobius *forficatus* of Leach's MSS.

Crustacea.

Inhabits Europe; is not very uncommon in many parts of England and Ireland, but has not yet occurred in Scotland or Wales.

Variegatus. *Sp.* 2. *Variegatus.* The whole under lip slightly punctulated with impressed dots; feet pale-testaceous-yellow, spotted with blackish-brown, or fuscous.

LITHOBIUS *variegatus.* Leach's MSS.

Discovered in Devonshire by Mr Leach, who was rather doubtful whether it is more than a variety of LITHOBIUS *forficatus*, but is now confident of its being distinct.

Lævilabrum. *Sp.* 3. *Lævilabrum.* Under lip very smooth, with lightly impressed obscure dots on the anterior part; feet testaceous yellow.

LITHOBIUS *lævilabrum*, Leach's MSS.

Common in Scotland in rocky places, living under stones, in fissures of rocks, and under moss.

84. Geophilus. GENUS LXXXIV. GEOPHILUS. Antennæ filiform, composed of fourteen nearly equal joints.

Electricus. *Sp.* 1. *Electricus.* Body linear and yellowish; feet about 140, (144 Latreille.)

SCOLOPENDRA *electrica*, Linné, Fabricius, Latreille; GEOPHILUS *electricus*, Leach's MSS.

Inhabits Europe.

This curious animal is found on decayed trees: it emits a dim phosphoric light as it moves along, often leaving behind it a shining track.

Observation. Besides the species of this family which have been here described, are many more inhabiting this country, but their natural history is so imperfectly understood, that we cannot at this time venture a description, lest we fall into error; much remains to be done, but should any species be accurately defined, we shall insert it under its proper head, together with all new discoveries in this and other classes, in the article ZOOLOGY.

Directions for preserving Crustacea for Cabinets.

Those species which inhabit the sea, should be suffered to remain for some hours in cold fresh water to extract the salt, which would soon destroy them by attracting moisture; they are then to be placed in a crawling posture, and the parts of the mouth are to be displayed by means of pins, until dry: they will then remain in that position. The more minute species must be dried, and afterwards stuck on paper with gum water, in different positions. Those of the last order, *Miriapoda*, are to be killed by immersion in spirits, and afterwards stuck with a pin on the right side. CRUSTACEA are kept in a cabinet lined with cork, to which they are affixed by pins; or in boxes loose: the former method is best, as they can then be moved from one place to another without trouble or risk. For a more particular account, we must refer to the article ENTOMOLOGY, where cabinets, modes of preparation, &c. will be found accurately detailed at full length.

CLASS II. ARACHNIDES.

Arachnides.

FROM ἀραχνη, a *spider*, and εἰδος, *resemblance*; a class of animals proposed as a distinct class by the celebrated Lamarck, Professor of Zoology in Paris, and established as such by Latreille and other eminent naturalists. As we mentioned in our introduction to this article, the animals composing this class were placed among Insects (INSECTA) by Linné, Fabricius, De Geer, and others; and in this light they were viewed by Latreille in his work on the genera of insects and crustacea; and he seems to have admitted them as a distinct class in his last work, rather through the persuasion of others than from his own judgment.*

In considering the classes CRUSTACEA and ARACHNIDES, we have, at the suggestion of Mr Leach, adopted an arrangement proposed by him, which contains some essential alterations, which, however, seem sufficiently warranted, as they tend to the ease of the student, and so far may prove much to the advancement of the science. By his arrangements, (which we have fully stated in our general remarks in the introduction to this article,) all those animals formerly considered as insects, without wings and antennæ, are placed in the class ARACHNIDES; consequently, the orders, 1. *Tetracera*, 2. *Myriapoda*, 3. *Thysanoura*, and 4. *Parasita* of Latreille, are rejected from this class: The two first are placed with the CRUSTACEA, and are considered as one order, to which the name *Myriapoda* is applied; the two latter he arranges with Insects, and places them in an order called by Linné *Aptera*. Of this we shall have occasion to speak more fully when considering the class INSECTA, under the article ENTOMOLOGY, and again comparatively in the article ZOOLOGY; it will therefore be unnecessary to take up the time of the reader, by saying any more on the subject at present; we shall therefore proceed to give the characters of the class ARACHNIDES, with those of its Tribes, Families, and Genera, after which the individual Species, with their structure and economy.

Anatomical Character.

No vertebræ; heart single; tracheæ † for respiration; feet for moving the body.

External Character.

Feet jointed, eight (rarely six) in number. Stigmata, or external openings of the tracheæ, visible. Body without wings. No metamorphosis, or scarcely any. No antennæ.

ORDER I. PODOSOMA.

BODY composed of segments, each segment being a continuation of the feet (at least apparently so.) HEAD distinct. THORAX not distinct from the body. FEET eight in number, each segment bearing one on each side.

TRIBE I. GNATHONIA.

Eyes four in number, placed on a tubercle on the anterior part of the body. *Ovifera* one on each side. *Mandibules.*

* See the Introduction to his *Considerations générales sur l'Ordre naturel des Crustaces, des Arachnides, et des Insectes.*

† Visible from the external openings.

Family I. Nymphonides.

Palpi two in number.

Genus I. Nymphon. Mandibules armed with a forceps.

Family II. Phoxichilides.

No palpi.

Genus II. Phoxichilus. Mandibules terminated by a simple bent nail.

TRIBE II. AGNATHONIA.

Eyes two in number. *Ovifera* none? *Mandibules* none.

Family III. Pycnogonumides.

No mandibules. No ovifera?

Genus III. Pycnogonum. Mouth furnished with a simple tube.

ORDER II. ELEUTEROSOMA.

Head connected with the thorax, which is generally distinct from the abdomen. Thorax feet bearing. Feet six or eight in number.

TRIBE I. HEXAPODA.*

Feet six in number.

Family IV. Astomides.

Feet six in number.

A. *Palpi and rostrum very conspicuous.*

Genus IV. Caris. Body consisting of one coriaceous piece, which is much depressed, and nearly orbicular.

Genus V. Leptus. Body soft and oval.

B. *Palpi and rostrum obscure.*

Genus VI. Astoma. Feet very short.

TRIBE II. OCTOPODA.

Feet eight in number.

A. *Abdomen* sessile, without any appearance of rings; *Mouth* generally produced into a rostrum or haustellum.

Family V. Hydrachnides.

Feet formed for swimming.

Genus. VII. Limnochares. Rostrum scarcely projecting.

Palpi without appendages.

Body depressed.

Mandibules none.

Genus VIII. Hydrachna. Mandibules none.

Rostrum conic, projecting, the points sharp.

Palpi projecting, the apex with a moveable appendage.

Genus IX. Elais. Mandibules depressed, the points armed with a nail.

Family VI. Ricinides.

Feet not formed for swimming; no mandibules; rostrum shaped like a bird's beak, or hunter's horn.

I. Eyes distinct. Body very soft and thick; the dorsal Skin not coriaceous.

* *Palpi obscure, not projecting.*

Genus X. Sarcoptes.

** Palpi more or less distinct.

Genus XI. Bdella. Palpi slender, filiform, long, and elbowed, the extremity armed with hairs.

Eyes four.

Posterior feet very long.

Genus XII. Smaris. Palpi slender, straight, and filiform, a little longer than the rostrum, without any setæ at the extremity.

Eyes two.

Anterior feet very long.

Genus XIII. Cheyletus. Palpi very thick, resembling arms.

II. Eyes indistinct: Body with a covering, partly membranaceous, partly coriaceous.

* *Palpi and rostrum obscure.*

Genus XIV. Uropoda. Feet very short; anus with a filament, by which it attaches itself to insects.

** *Palpi and rostrum distinct.*

Genus XV. Argas. Palpi short, conic, and free, not covering the rostrum.

Genus XVI. Ixodes. Palpi short and depressed, embracing the rostrum, and sheathing it.

Family VII. Acarides.

Feet not formed for swimming; with mandibules.

I. Palpi very short, and not projecting.

Genus XVII. Acarus. Body very soft. Mouth naked.

Genus XVIII. Oribita. Body covered wirh one coriaceous plate. The rostrum covering the parts of the mouth.

II. Palpi projecting.

* *No hook or moveable appendage at the extremity of the palpi.*

Genus XIX. Gamasus.

** *An hook or moveable appendage at the apex of the palpi.*

Genus XX. Erythræus. Body not divided. Eyes sessile.

Genus XXI. Trombidium. Body divided into two parts; the anterior division bearing the eyes, the mouth, and two first pairs of feet.

Eyes pedunculated.

B. Abdomen fixed or sessile, sometimes ringed. Mouth not prolonged into an haustellum or rostrum.

Family VIII. Phalangides.

Mandibules armed at their points with forceps; abdomen generally sessile; anus without tubercles of nipples.

I. Eyes not placed on a peduncle or tubercle.

Genus XXII. Siro. Mouth naked: Mandibules very long.

Genus XXIII. Trogulus. Mouth situated in a cavity, under the anterior part of the thorax; mandibules short.

II. Eyes placed on a common tubercle.

Genus XXIV. Phalangium. Eyes two. Palpi terminated by a hook. Body orbicular.

Genus XXV. Galeodes. Eyes four; palpi with no hook; body elongated.

* In the Appendix we have added two other genera to this tribe, viz. Nycteridia, which Latreille places with the Insecta, and a new genus, named by Dr Leach Ocypete.

Family IX. Araneides.

Mandibles terminated by a simple hook or nail; abdomen connected closely with the thorax; anus with nipples.

I. Feet not formed for leaping.

1. Hinder eyes not placed on the anterior and superior part of the thorax; not forming an irregular hexagon.

A. The two exterior nipples longer than the rest, cylindrical, and projecting. Lip not advanced between the maxillæ, nor prominent, but much longer than broad.

a. Mandibules projecting.

Genus XXVI. Mygale. Palpi inserted on the extremities of the maxillæ.

Genus XXVII. Atypus. Palpi inserted towards the base of the maxillæ. Lip quadrate, not prominent.

Genus XXVIII. Eriodon. Palpi inserted towards the base of the maxillæ; lip prominent, long, and narrow.

b. Mandibules perpendicular.

* *Six eyes.*

Genus XXIX. Segestria. Eyes disposed in a transverse line, crooked behind, at each extremity.

Genus XXX. Dysdera. Eyes disposed in nearly an oval form, open in front.

** Eight eyes.

Genus XXXI. Filistata. Maxillæ much inclined towards the lip; with no sinus or groove at the insertion of the palpi, they being inserted at the hinder side. Lip much longer than broad. The fourth, then the first pair of feet, longest. Eyes placed on an uneven elevation; the four anterior ones forming a semicircle open in front; the four hinder ones disposed in a nearly straight and transverse line.

Genus XXXII. Drassus. Maxillæ much inclined towards the lip, with no groove at the insertion of the palpi. Lip longer than broad. The fourth pair of feet, and then the first, longest. Eyes not placed on an elevation, disposed in two slightly curved (nearly straight) lines; those of the hinder line not geminated.

Genus XXXIII. Clotho. Maxillæ much inclined towards the lip, without a groove at the insertion of the palpi. Lip not much longer than broad. The fourth pair of feet, then the second, afterwards the third, longest. Eyes close, disposed in four and four, in two transverse lines, bent slightly backwards in an arched and somewhat concentric manner; those of the hinder line disposed in pairs, (geminated.)

Genus XXXIV. Clubiona. Maxillæ nearly straight, with a groove at the insertion of the palpi, the apex rounded, and obliquely truncated on the inside; evidently longer than the lip. Eyes disposed four and four in two transverse lines; the anterior line straight, the posterior much longer, bent slightly backwards.

Genus XXXV. Aranea. Maxillæ nearly straight, with a groove at the insertion of the palpi. Apex rounded, the internal angle truncated, remarkably longer than the lip. Lip nearly equal. Eyes disposed in two lines, bent backwards.

Genus XXXVI. Argyroneta. Maxillæ nearly straight, with a groove at the insertion of the palpi. Lip shorter than the maxillæ. The four middle eyes disposed in a quadrate form, the lateral ones geminated.

B. All the nipples short, and nearly equal, of a conic form. Lip projecting between the maxillæ, being much broader than long.

a. Eyes not describing the segment of a circle.

* *Maxillæ straightened towards their extremities, not dilated.*

Genus XXXVII. Scytodes. The first and the fourth pair of feet longest. Eyes six.

Genus XXXVIII. Theridion. The first and the fourth pair of feet longest. Eyes eight; the four middle ones arranged in a quadrangle, the inferior ones being placed in a common elevation; the other two geminated, and placed on an eminence on each side.

Genus XXXIX. Latrodectus. The first, and then the second pair of feet longest. Eyes eight, disposed four and four in two transverse and parallel straight lines.

Genus XL. Pholcus. The first, and then the second pair of feet longest. Eyes eight; placed on a tubercle; three on each side in a triangle, and two in the middle; anteriorly.

* *Maxillæ dilated at their points, and straight.*

Genus XLI. Uloborus. The first, and then the fourth pair of feet longest. Eyes eight, equal, very minute, placed at nearly equal distances from one another, on two transverse lines. The two middle ones a little nearer than the others; the anterior line bent backwards, the posterior bent forwards.

Genus XLII. Tetragnatha. The first, and then the second pair of feet longest. Eyes eight, and equal, disposed four and four in two straight transverse parallel lines.

Genus XLIII. Linyphia. The first, and then the second pair of feet longest. Eyes eight, the four middle ones forming a square, which is narrow in front, the other four geminated, and placed two on each side.

Genus XLIV. Epeira. The anterior, and then the second pair of feet longest. The four middle eyes forming an equal-sided square; the other four placed in pairs, two on each side.

b. The eyes describing the segment of a circle.

Genus XLV. Episenus. Maxillæ straight; lip much broader than long; the first, and then the fourth pair of feet longest.

Genus XLVI. Micrommata. Maxillæ straight; lip much broader than long; the second feet, and then the first pair longest.

Genus XLVII. Thomisus. Maxillæ inclined; lip much longer than broad; the second and the first pair of feet longer than the rest.

2. Hinder eyes placed on the anterior and superior part of the thorax, forming an irregular hexagon.

A. *The anterior feet longest, next to these the second.*

Genus XLVIII. Oxyopes. Maxillæ straight, and remarkably longer than the lip; eyes in four transverse lines.

Genus XLIX. Storena. Maxillæ inclined, much longer than the lip; eyes in three transverse lines.

Genus L. Ctenus. Maxillæ straight, and remarkably longer than the lip; eyes disposed in three transverse lines.

B. The fourth pair of feet longest.

Genus LI. Lycosa. Lip much longer than broad; the fourth feet and then the first longest.

Genus LII. Dolomedes. Lip not much longer than broad; the fourth pair, and then the second pair, of feet longest.

II. Feet formed for leaping.

Genus LIII. Eresus. The four middle eyes forming a quadrangle; on the outside of which the others are placed, as if forming another quadrangle to inclose them.

Arachnides.

GENUS LIV. SALTICUS. Eyes forming a horse-shoe or parabole open behind.

FAMILY X. TARANTULIDES.

Palpi very spiny, resembling arms; mandibules terminated by a simple hook; the two anterior feet very long, and antennæform; the tarsi with an immense number of joints.

GENUS LV. TARANTULA. Palpi long, simply terminated by a joint in the form of a hook; body short and depressed; thorax reniform or lunated; tail none.

GENUS LVI. THELYPHRONUS. Palpi short and thick, terminated by a finger and thumb; body oblong and cylindrical; thorax oval; tail long.

FAMILY XI. SCORPIONIDES.

Palpi arm-shaped, terminated by a hand armed with a forceps; mandibules with a pair of forceps; all the feet alike in form.

GENUS LVII. SCORPIO. Eyes six or eight; tail jointed; two laminated pectens at the base of the belly.

GENUS LVIII. CHELIFER. Eyes two or four; tail none; pectens none.

GENUS LIX. CELLULARIA.

Observation. Besides the genera above defined, we may add one more, viz. CELLULARIA, a most singular animal discovered by the celebrated zoologist Montagu, inhabiting the cellular membrane of the gannet, (*Pelicanus Bassanus*, Linn.) which is not referable (as far as we can judge from his description) to any of the families hitherto established by Latreille. It appears to be intermediate between *Acarides* and *Ricinides*; we shall, however, quote his description, as given in the first volume of the Wernerian Society's Memoirs, page 191.

"Ovate oblong, smooth, glossy white, with eight short legs, furnished with several joints, and terminated by bristles, two on each side approximating, and near to the anterior end; the others similarly disposed, about one-third of its length from the posterior end: of the posterior legs, the hindermost pair is furnished with a very long bristle, the other pair usually with two; the anterior legs possess several bristles each. No other appendages were discernible under the best constructed microscope, not even the mouth or eyes could be clearly ascertained; but beneath, at the anterior end, from whence the fore legs arise, there are four light depressions, surrounded by dark lines, in the two hindermost of which is a dark spot, but these had not the appearance of eyes; behind this part is usually a fold in the skin, at which place there is an independant motion: the feet are also observed to be in continual alternate motion, whilst under the microscope.

"Size of ACARUS *Siro*, or cheese mite.

"As far as I have hitherto observed, this insect is peculiar to the gannet, and does not appear to inhabit any other part than the cellular membrane: in some subjects it is found in prodigious abundance, together with the ova; and no instance has occurred in which it has not appeared more or less in every specimen dissected.

"To class this animal with any of the Linnæan genera is impossible; nor am I acquainted with any genus, in the arrangement of any of the more modern systematic writers, in which it could with propriety be placed. It appears to be more nearly allied to *Acarus* than any other; but the want of eyes, proboscis or sucker, and palpi, will admit of no connection; the situation, too, of the legs seems to be characteristic. Under these circumstances, I propose giving it a distinct place in the system of nature, under the title of CELLULARIA *Bassani*, with the following generic characters: Head, thorax, and abdomen united; no eyes, antennæ, palpi, nor proboscis; legs eight, the four posterior remote from the four anterior; feet unarmed, but furnished with bristles."

From the above ingenious account, which is accompanied with figures, it is evident that it should form a distinct family, which might with propriety be named *Cellularides*, and be placed, as we have before mentioned, between the *Mites* and *Tiques*.

ORDER I. PODOSOMA.*

Genera and Species.

FAMILY I. NYMPHONIDES.

1. NYMPHON.

GENUS I. NYMPHON. *Fabr. Lamar. Latr.* PYCNOGONUM. *Oth. Fabr. Mall.* PHALANGIUM. *Linn. Mont.*

Mandibulæ armed with a forceps.

Grossipes.

Sp. 1. *Grossipes.* Body smooth; feet very long.

Phalangium grossipes. Linné.

Nymphon grossipes. Fabr. Latr.

Pycnogonum grossipes. Otho Fabricius, Müller.

Inhabits the Norwegian and British seas; is not uncommon on most of our rocky coasts, being often dredged up by the fishermen, who know it by the name of *sea spider.* Fabricius says it perforates the shells of mussels, (*mytilli*,) and sucks out the softer parts of the animal.

Aculeatum.

Sp. 2. *Aculeatum.* Body smooth; feet very long and hairy about the joints.

Phalangium aculeatum. Montagu.

Nymphon hirtum. Fabr.?

Phalangium hirtum. Turton.?

Inhabits the British sea.

Colour, when alive, dusky black; length about four lines.

This species was first noticed by George Montagu, Esq. on the south coast of Devonshire. This is not the *Phalangium spinipes* of Otho Fabricius and Gmelin, as has been supposed by Montagu, that species being referable to the following genus.

FAMILY II. PHOXICHILONIDES.

2. PHOXICHILUS.

GENUS II. PHOXICHILUS. *Latr.* PYCNOGONUM. *Otho Fabr.* PHALANGIUM. *Montagu, Gmel.*

Mandibulæ simple, without a forceps.

Spinipes.

Sp. 1. *Spinipes.* Feet very long and spinous.

Phoxichilus spinipes. Latreille.

Pycnogonum spinipes. Otho Fabricius.

Phalangium spinipes. Gmelin.

Phalangium spinosum. Montagu.

Inhabits the Norwegian and British seas.

This species, which is certainly *Phalangium spinosum* of Montagu, when alive is of a rufous-brown colour, and about a quarter of an inch in length. Two specimens, which were most obligingly communicated by R. Stevenson, Esq. from the Bell-rock light-house, on

* All the animals of this order are marine, and for the most part inhabit deep water or rocky shores: they frequently occur also in pools left by the receding tide. The females of the first tribe are furnished with long jointed ovifera, which Latreille has improperly named spurious feet, the use of which are to carry about their eggs. The same parts are said to be found in the second tribe in *Pycnogonum Balænorum*; but we have never been fortunate enough to detect them in any specimens we have hitherto examined. See *Linn. Trans.* vol. ix. p. 101. where this is noticed by our celebrated zoologist Montagu.

Arachnides.

the Scottish coast, in a living state, were of a blood-red colour, and are possibly distinct.

FAMILY III. PYCNOGONIDES.

3. PYCNOGONUM.

GENUS III. PYCNOGONUM. *Brunnich. Muller. Oth. Fabr. Joan Fabr. Oliv. Lam. Latr.* PHALANGIUM. *Pennant; Gmelin. mandibules* none.

Balænarum.

Sp. 1. *Balænarum.* Body rufous or dusky.

Pycnogonum balænarum. Fabr. Latr.

Phalangium balænarum. Pennant, Gmelin.

Inhabits the rocky shores of the European Ocean, getting under stones, or running on the rocks at low water. It is sometimes also taken by the dredge, in deep water, on many parts of our coasts, but is not common. Mr Sowerby has observed them amongst the oysters in the London shops occasionally. See Plate CCXXI. Fig. 11.

PLATE CCXXI. Fig. 11.

ORDER II. ELEUTEROSOMA.

Eleuterosoma.

FAMILY IV. ASTOMIDES.

A. *Palpi and Rostrum very conspicuous.*

4. CARIS.

GENUS IV. CARIS. *Latreille.* ACARUS. *Geoff.*

Rostrum conic and porrected from the maxillæ.

Palpi somewhat conic, four-jointed, porrected, and as long as the rostrum.

Body coriaceous, somewhat orbicular and depressed.

Vespertilionis.

Sp. 1. *Vespertilionis.* Body brown.

Caris Vespertilionis. Latreille.

Inhabits bats.

5. LEPTUS.

GENUS V. LEPTUS. *Latr.* PEDICULUS. *Scopoli.* ACARUS. *Shaw, Fabricius.* TROMBIDIUM. *Hermann.*

Mouth furnished with a porrected rostrum.

Palpi short and somewhat conic.

Body soft and generally oval.

Phalangii.

Sp. 1. *Phalangii.* Body oval, bright red, with an elevation in front, and two black eyes; rostrum somewhat conic; base of the palpi much thickened; feet nearly equal in length.

Pediculus coccineus. Scopoli.

Acarus Phalangii. Fabricius.

Leptus Phalangii. Latreille.

Inhabits several insects, especially *Phalangium Opilio.*

Obs. To this genus, according to Latreille, all the *trombidia hexapoda* (six-legged trombidia) of Hermann, and the *acarus autumnalis* of Shaw's *Naturalist's Miscellany*, are referable.

B. *No rostrum; the parts of the mouth very obscure.*

. ASTOMA.

GENUS VI. ASTOMA. *Latreille.*

Mouth nearly obsolete.

Body soft and oval.

Feet very short.

Parasiticum.

Sp. 1. *Parasiticum.* Body bright red, somewhat contracted in the middle.

Astoma parasiticum. Latreille.

Inhabits mosses and insects.

II. *Eight Feet.*

FAMILY V. HYDRACHNIDES.

A. *No mandibulæ.*

LIMNOCHARES.

GENUS VII. LIMNOCHARES, *Latreille.* ACARUS, *Linn. Geoff. De Geer.* TROMBIDIUM. *Fabr.*

Palpi bent inward, without appendices.

Rostrum scarcely prominent.

Body depressed, and tomentose.

Feet short, the four posterior ones distant.

Holosericea.

Sp. 1. *Holoserisea.* Body ovate, rough and soft, with two black eyes.

Acarus aquaticus. Linné.

Trombidium aquaticum. Fabricius.

Limnochares holosericea. Latreille.

Inhabits the waters of Europe; is very common in our ponds during the summer months. It varies in colour, but is most frequently found bright red and greyish red, with all the intermediate varieties of shade. Fabricius says it deposits eggs of a red colour, or nepæ, (water scorpions.)

8. HYDRACHNA.

GENUS VIII. HYDRACHNA. *Müll. Oliv. Latr.* ACARUS. *Linn. Geoff. De Geer.* TROMBIDIUM. *Fabr.*

Palpi somewhat cylindrical, porrected, consisting of four joints, the last sharp, and armed with a moveable appendage.

Mouth produced into a porrect, conic rostrum.

Maxillæ two, lengthened, setaceous, and sharp, capable of being concealed by the lip.

Body globular.

Feet placed at an equal distance from one another, fimbriated with hair.

Geographica.

Sp. 1. *Geographica.* Body black, with points and spots of red.

Hydrachna geographica. Müll. Latr.

Trombidium geographicum. Fabr.

Inhabits slowly flowing waters and ponds. The largest species hitherto discovered.

Cruenta.

Sp. 2. *Cruenta.* Body blood red; feet equal.

Hydrachna cruenta of Müller and Latreille.

Trombidium globator. Fabricius.

Inhabits the European waters.

B. *With Mandibulæ.*

9. ELYAIS.

GENUS IX. ELYAIS. *Latr. Lam.* HYDRACHNA. *Müll. Oliv.* TROMBIDIUM. *Fabr.*

Mandibules depressed, armed with a nail at their points, and received within the lip.

Palpi oblong-conic, bent, sharp, and consisting of three or four joints.

Eyes four.

Extendens.

Sp. 1. *Extendens.* Body round, shining, smooth, and red without spots; posterior feet very smooth.

Hydrachna extendens. Müll.

Trombidium extendens. Fabricius.

Elyais Extendens. Lamarck, Latreille.

Inhabits stagnant waters throughout Europe.

Obs. Latreille, in his *Genera Crustaceorum et Insectorum*, says, he suspects the following HYDRACHNÆ of Müller, viz. *undulata, fuscata, maculata, umbrata,* to belong to the genus ELYAIS. This future observers must decide.

FAMILY VI. RICINIDES.

I. *Eyes distinct. Body very soft and thickish, the dorsal skin not coreaceous.*

A. Palpi obscure.

10. SARCOPTES.

GENUS X. SARCOPTES. Latr. ACARUS *of authors.*

Passerinus.

Sp. 1. *Passerinus.* Third feet very thick.

Acarus passerinus. Linn. Fabr. Herm.

Pulex Sturni. Redi (*Opuscul, tom.* 1. *tab.* 2. *fig.* 4.)

Sarcoptes passerinus. Latr.

Inhabits birds.

Scabiei.

Sp. 2. *Scabiei.* Body somewhat round; feet short, reddish; the four posterior ones bearing a very long seta; the anterior four terminated by a club.

Acarus scabiei. Fabricius.

Sarcoptes scabiei. Latreille.

Inhabits ulcers in the itch. A good figure is given by Latreille, in his work entitled *Hist. natural des Crus-*

Arachnides. *taces et des Insectes*, tom. 7. pl. 66. fig. 8. under the name *sarcopte de la gale*.

Obs. To this genus the following species seem to belong, *Acarus exulcerans*, Linné; *Acarus destructor* of Schrank, (*Enumeratio Insectorum Austriæ*, No. 1057.) and *Acarus torosus* of Hermann.

B. Palpi apparent.

11. Bdella. Genus XI. Bdella. *Latr. Lam.* Acarus. *Linn. Fabr.* Scirus. *Her.*

Palpi elongate and generally geniculated, the last joint with two distinct long setæ or hairs.

Mouth with an elongate, depressed, conic rostrum; defended by three valves, or nearly equal lanceolate setæ.

Body ovate, transversely divided into two parts.

Eyes four.

Feet posterior, longer than the rest.

Rubra. Sp. 1. *Rubra.* Antennæ geniculated, the second and third joints very short; the first and last elongate; rostrum longer than the thorax, subulated; body blood red; feet pale.

Bdella rubra, Lamarck.

Acaris longicornis, Linn.?

Inhabits Europe, under stones.

Observe. Scirus longirostris of Hermann, appears to be not very distinct from the above species; p. 62. tab. 6. fig. 12. He mentions two other species, viz. *Latirostris*, and *Setirostris*; the *first* is distinguished by its rostrum being shorter than the thorax; the antennæ three-jointed, the last joint shortest: the *second*, by its subulate rostrum, antennæ with two joints, the apex with one seta. They both inhabit mosses, and are of a red colour.

12. Smaris. Genus XII. Smaris. *Latr.* Acarus *Schrank.* Trombidium, *Hermann.*

Mouth with an elongate, somewhat cylindrical porrected rostrum, with the apex gradually becoming narrower.

Palpi nearly parallel, straight, subcylindrical, and porrected, consisting of four joints, the last with no elongate setæ; they are a little longer than the rostrum.

Body oval and scaly.

Eyes two.

Feet, anterior ones longer; the four hinder distant.

Sambuci. Sp. 1. *Sambuci.* Body red.

Acarus sambuci. Schrank.

Trombidium sambuci, Hermann.

Smaris sambuci, Latr.

Inhabits trees, especially the elder.

13. Cheyletus. Genus XIII. Cheyletus. *Latr.* Acarus, *Schrank.*

Palpi very thick, resembling arms.

Eruditus. Sp. 1. *Eruditus.* Body brownish.

Acarus eruditus, Schrank.

Cheyletus eruditus, Latr.

Inhabits books and musæa.

II. Eyes indistinct. Body with a covering, partly membranaceous, partly coriaceous. The haustellum with three horny laminæ toothed on the side; (these animals suck the blood of mammalia, birds, and reptiles.)

A. Rostrum and palpi obscure.

14. Uropoda. Genus XIV. Uropoda, *Latr.* Acarus, *De Geer, Donovan, Schaw.*

Feet very short (when at rest pressed and contracted against the under part of the body), the fourth longest, then the third; the first very short, received into a cavity on the anterior part of the body beneath.

Body oval, inclining to orbicular; back horny and shield-formed, the middle gradually convex; the under part smooth. The anus fixed to coleopterous insects by a long filiform peduncle. Arachnides.

Sp. 1. *Vegetans.* Body brown, very smooth and shining. Vegetans.

Acarus vegitans, De Geer, Shaw.

Acarus coleoptratorum, jun. Donovan.

Uropoda vegitans, Latreille.

Inhabits sphæridea, histeres, scarabæi, and aphodii.

This curious animal is found on most of the dung-feeding coleopterous insects. Donovan has figured this species for the young of *Gamasus coleoptratorum.*

B. Rostrum and palpi distinct.

Genus XV. Argas, *Latr.* Rhynchoprion, *Herman.* Acarus, *Fabr.* 15. Argas.

Palpi conic, short, incurved, consisting of four joints.

Body oval, membranaceous, the skin not more coreaceous before than behind.

Feet arising from nearly the middle of the vertex, with two nails at their extremities, inserted and elongated, the joints rounded at their base.

Sp. 1. *Reflexus.* Pale yellowish, or flesh-coloured inclined to violet; body marginated, the squamulæ very short, the sanguiferous vessels branched. Reflexus.

Acarus marginatus, Fabr. Coquebert.

Argas reflexus, Latr.

Inhabits houses, sucking the blood of pigeons.

Observe. Latreille thinks it highly probable that *Acarus niger* of De Geer, (tom. 7. pl. 37. fig. 9.), and *Rhyncoprion americanum* of Hermann, (p. 71.) form an intermediate genus between *Argas* and the following genus *Ixodes.* Should this be found correct, it might be named *Rhychoprion*, which would prevent any useless confusion arising from synonyms.

Genus XVI. Ixodes, *Latr.* Acarus, *Lin. Fab. Oliv.* Cynorhestes, *Herm.* 16. Ixodes.

Palpi terminal, porrect, very short, coriaceous, plain, depressed, longer than broad, nearly of an equal breadth, the apex rounded or obtuse, inserted at the base of the haustellum on a common peduncle, sheathing the haustellum and rostrum.

Rostrum oblong-quadrate, depressed, obtuse, three-jointed; the basilar joint very small; the others nearly equal; the internal edge hollow.

Haustellum horny, with three lamellæ.

Body ovate-orbicular, membranaceous before, and notched for the insertion of the rostrum; the anterior part of the back coriaceous, somewhat resembling a thorax.

Feet inserted at the lateral margins, the joints thick; the last, with two nails, inserted on a vesicle; the vesicle pedunculated.

Sp. 1. *Ricinus.* The rostrum, thoracic mark on the dorsum, and feet blackish red; the abdomen light red, with a few scattered villi, the sides marginatis; the palpi free, or scarcely sheathing the haustellum. Ricinus.

Acarus ricinus, Linn. Fabr.

Ixodes ricinus, Latr.

Inhabits the woods and groves of Europe, attaching itself to oxen and dogs, and adhering firmly by their rostrum and feet. Is very common in Britain; is known by the names tick, or dog-tick, or tique.

Sp. 2. *Sanguineus.* Blood red, and punctated or dotted, with three impressed lines behind; the dorsum without any distinct mark on the anterior part. Sanguineus.

Inhabits France, and is here given on the authority of that celebrated entomologist Latreille, who says it is rather smaller than the preceding species.

Reticulatus. *Sp.* 3. *Reticulatus.* Bright blood red beneath, above whitish, variegated, with brownish blood colour; the dorsal marks obscurely marginated; the sides of the abdomen marginated, punctated, and striated; palpi somewhat oval.

Acarus reticulatus, Fabr.
Acarus reduvius, Schrank.
Ixodes reticulatus, Latr.

Inhabits various plants; is very common in Genistæ; it fixes itself to oxen. When its abdomen is distended, it is nearly five lines in length, and is then of an ash or pale yellow colour.

Family VII. Acarides.

I. Palpi very short, not exserted.

17. Acarus. Genus XVII. Acarus, *Linn. Geoff. De Geer. Fabr. Oliv. Hermann.*

Body soft; parts of the mouth naked.

Tarsi with a pedunculated vesical at the apex.

Siro. *Sp.* 1. *Siro.* Whitish, with two brown spots; body oval, contracted in the middle, with very long hairs; feet equal in length.

Acarus siro, Linn. Fabr.
Ciron du fromage, Geoff.
Acarus domesticus, Latr.

Inhabits cheese and flour too long kept. Is called cheese-mite, and much esteemed by most people, who say it heightens and improves the flavour of cheese. Latreille supposes *Acarus dimidiatus* of Hermann may be this species.

Farinæ. *Sp.* 2. *Farinæ.* Oblong and white; head reddish; feet conical, thicker, and of an equal length.

Acarus farinæ, Schrank, Latreille.
Acarus favorum, Hermann?

Observe. Are *Acarus lactus* and *Dysenteriæ,* of Linné and Fabricius, distinct from *Acarus farinæ* of Latreille? They are probably merely the young of that species.

18. Oribita. Genus XVIII. Oribita, *Latr.* Acarus, *Linn. Fabr. Oliv. Geof.* Notaspis, *Her.*

Body with a coriaceous covering, (back generally shielded,) rostrated before; the rostrum including the parts of the mouth.

Tarsi, generally with three nails at their extremities.

* *Abdomen somewhat globose, neither angulated in front, nor furnished with wing-like processes.*

Geniculata. *Sp.* 1. *Geniculata.* Brownish red, shining and hairy; feet pale-brown; thighs rather clubbed.

Acarus geniculatus. Linn.
Oribita geniculata. Latreille.

Inhabits trees and stones in various parts of Europe.

Theleproctus. *Sp.* 2. *Theleproctus.* Black; back clypeated; the shield divided and striated by concentric circles.

Notaspis theleproctus. Hermann.
Oribita theleproctus. Latreille.

Inhabits France and Scotland. Its form is that of a shield, its motion very slow.

Cassidea. *Sp.* 3. *Cassidea.* Brownish-red; scutum depressed and transparent; anterior feet antennæ-like.

Notaspis cassidea. Herm.
Oribita cassidea. Latr.

Inhabits mosses. Is found in France and Britain; in the latter country it is very common.

** *Abdomen somewhat globose; the anterior margin produced into an angle, or wing-like process.*

Alata. *Sp.* 4. *Alata.* Abdomen very smooth; obscurely brownish red; the sides with wing-like processes.

Acarus coleoptratus. Linn.
Oribita alata. Latr.
Notaspis alata. Herm.

Inhabits mosses.

Sp. 5. *Humeralis.* Abdomen blackish-brown-red, and very smooth; the sides produced into a straight angular membranaceous process. Humeralis.

Notaspis Humeralis. Herm.
Oribita Humeralis. Latr.

*** *Abdomen somewhat quadrate, neither angulated nor winged.*

Sp. 6. *Tegeocrana.* Abdomen oblong; the anterior margin with four white setæ; the head covered by a triangular scutum; the lateral squamula pellucid. Tegeocrana.

Notaspis tegeocrana. Herm.
Oribita tegeocrana. Latr.

Inhabits mosses.

Sp. 7. *Horrida.* Body rough; abdomen with two teeth behind, and four hooked processes. Horrida

Notaspis horrida. Hermann.
Oribita horrida. Latreille.

Inhabits mosses. In this country it appears to be very rare, having been found but once in a wood in Norfolk, near Cossey, by Mr Leach.

I. *Palpi exerted and prominent.*

A. No moveable appendage at the extremity of the palpi.

Genus XIX. Gamasus, *Latr.* Acarus, *Linn. Fabr. Oliv. Herm.* Trombidium, *Herm.* 19. Gamasus.

Pulvilli vesicular at the apex of the tarsi.

* *Body depressed; the whole, or part of the skin of the back, coriaceous.*

Sp. 1. *Coleoptratorum.* The anterior part of the back, and a triangular spot behind, coriaceous and fuscous; the anterior and posterior pair of feet rather longer than the rest. Coleoptratorum.

Acarus coleoptratorum. Linn. Fabr. Donovan. Herm.
Gamasus coleoptratorum. Latr.

Inhabits the dung of oxen and horses, attaching itself to such coleopterous insects as come there to feed or deposit their eggs. We have frequently seen Geotrupes *stercorarius,* (the common clock, or dor beetle,) and Necrophorus *vespilo* and *humator,* (grave-digging beetles,) nearly covered by hundreds of these animals.

Sp. 2. *Marginatus.* Oval, brown, and hairy; coriaceous above and below; the sides of the abdomen being alone membranaceous and white; the anterior feet nearly twice as long as the rest. Marginatus.

Acarus marginatus. Hermann.
Gamosus marginatus. Latreille.

Inhabits dung and putrescent plants, where it frequently occurs. Latreille supposes *acarus cellaris* of Dr Hermann is the same insect; it differs, however, in having very unequal feet, and an immarginate body; if his figure therefore be correct, it is a distinct species.

Sp. 3. *Crassipes.* Second pair of feet very thick and toothed. Crassipes.

Acarus crassipes. Hermann.
Gammasus crassipes. Leach's MSS.

Obs. To this family, *acarus testudinarius* of Hermann, (tab. 9. fig. 1.) and *acarus longipes,* (tab. 1. fig. 8.) of the same author appear to belong; but as we have never seen the animals, we cannot be too cautious in giving our opinion.

** Body with a soft skin, back not coriaceous.

Obs. We are unacquainted with all the members composing this family; and shall therefore give Latreille's ideas on the species which he supposes to belong to it. "Some few of the Trombidia and Acari of Hermann

Arachnides.

and Fabricius may be referred to this family. I have not examined the species with sufficient attention, the following list I therefore give with doubt, viz. *Trombidium.* 1. *Trimaculatum.* 2. *Miniatum.* 3. *Parietinum,* (*Acarus baccarum,* Linn.?) 4. *Congenericum.* 5. *Lapidum.* 6. *Telarium.* 7. *Sociale* of Hermann. *Trombidium trimaculatum* is figured by Rossi. *Acarus Hirundinis,* and *Vespertilionis* seem to form a distinct genus."

B. A moveable appendage at the extremity of the palpi.

20. Erythræus. GENUS XX. ERYTHRÆUS, *Latr.* ACARUS, *De Geer.* TROMBIDIUM, *Herm.*

Eyes two, sessile.

Palpi elongate and conic; the under part of the last joint armed with a chelate moveable appendage.

Body entire; the division between the two anterior pair, and posterior pair, not very remarkable.

Phalangioides. *Sp.* 1. *Phalangioides.* Feet very long, the last joint broad and compressed; the hinder, and then the anterior, longest; body obscurely red, with a yellowish orange band.

Trombidium phalangioides. Hermann.

Erythræus phalangioides. Latreille.

Inhabits the ground, running with rapidity; is found throughout the greater part of Europe; found by Mr Leach at Swansea.

21. Trombidium. GENUS XXI. TROMBIDIUM, *Fabr. Oliv. Lam. Latr. Herm.* ACARUS, *Linn.*

Eyes four, two on each side, pedunculated.

Palpi elongate-conic, inserted at the base of the posterior sides of the lip; consisting of four joints, the first very short, the second larger than the third, the last conic; the point (at least) horny, nail-shaped, acute; the base with a moveable cylindrical appendage.

Body divided into two parts; the anterior part thoracic, stronger and narrower, bearing the mouth, eyes, and four anterior feet; the posterior part abdominal, broader, very soft, bearing the four posterior feet, which are at a notable distance from the others.

Observe. Besides the above character, which is essential, we may subjoin the following. Mandibulæ two, compressed and horny, incurved at their base. Lip (*labium*) membranaceous, somewhat conic, sheathing the mandibulæ. Feet six, jointed, with two very short nails, which are compressed and arched, being concealed in a fissure in the middle of the apex of the tarsus; the anterior ones generally longest.

Tinctorium. *Sp.* 1. *Tinctorium.* Body somewhat quadrate; blood red, immaculate, and covered by a velvety down; the hairs setaceous, elongate, and bearded.

Acarus tinctorius, Linné.

Trombidium tinctorium, Fabr. Herm. Latr.

Inhabits Guinea; is often preserved amongst collections of insects from that place, whence we infer it is not an uncommon species. Its colour is destroyed by alcohol.

Holosericeum. *Sp.* 2. *Holosericeum.* Body somewhat quadrate; blood red, without spots, and tomentose; the down short, composed of hairs, or cylindrical papillæ, rounded or obtuse at their points.

Inhabits Europe; common, in the spring, on walls and trees in gardens. It is the *Acarus holosericeus* of Linné; *Trombidium holosericeum* of Fabricius, Hermann, and Latreille.

Fuliginosum. *Sp.* 3. *Fuliginosum.* Body elongate-quadrate, of an immaculate obscure red colour, and tomentose; the down short, with bearded hairs.

Trombidium fuliginosum, Hermann, Latreille.

Arachnides.

FAMILY VIII. PHALANGIDES.

I. EYES not placed on a common peduncle, but at some distance from each other.

22. Siro. GENUS XXII. SIRO, *Latreille.*

Mouth naked, with two mandibules, which are double-jointed, cylindrical, and compressed, with their points armed with forceps placed between two long narrow maxillæ, which are marginated on their inner edge.

Palpi two, composed of five elongate joints, the second the longest.

Body oval.

Eyes two in number, situated on the sides of the thorax, on an erect tubercle, at a distance from one another.

Abdomen annulated above and below.

Feet elongate and filiform; the tibiæ and tarsi consisting of two joints; the last larger and clavate, being armed with a bent nail.

Sp. 1. *Rubens.* Pale red; feet lighter coloured. Rubens.

Siro rubens, Latreille.

Inhabits France, harbouring under moss at the roots of trees. Length about a line.

GENUS XXIII. TROGULUS, *Latr.* PHALANGIUM, *Linn. Fabr.* 23. Trogulus.

Mouth situated in a cavity under the anterior part of the thorax, furnished with two mandibulæ, palpi, and maxillæ.

Mandibles cylindrical, elongate, compressed, double-jointed and kneed, the last joint armed with a forceps, and nearly equal chelæ.

Palpi filiform, a little longer than the mandibulæ, inserted at the internal lateral base of the maxillæ, and consisting of five joints; the first very short; the second very long and cylindrical; the third and fourth of a moderate and nearly equal length, of a cylindrico-conical form, the fourth a little longer; the last cylindrical, inclining to oval, armed at the apex with a very minute horny nail.

Maxillæ somewhat horny, oval, spoon-shaped, marginated, and divaricating.

Lip-like body; at the angle of separation small, membranaceous, and nearly round; seemingly formed of two moon-shaped parts joining together, the intermediate space receiving the apex of the chelæ.

Body ovate-elliptical, depressed, marginated in front, rounded at the apex.

Eyes two, placed at a short distance from one another on the back, the insertion scarcely prominent.

Feet eight, elongate, filiform, each arising from a common base separate from the pectus; the second and fourth pair longest, and of nearly an equal length; next the third, then the first: The tibiæ and conæ consisting of two, the tarsi of three joints; the first joint of the latter, and then the last, longest; last joint of tarsus armed with a nail.

Sp. 1. *Nepæformis.* Obscure-cinereous, or brownish; the dorsum and sides of the abdomen obscurely carinated; the external apex of the first joint of the tarsi lengthened. Nepæformis.

Phalangium tricarinatum, Linné.

Phalangium carinatum, Fabricius.

Acarus nepæformis, Scopoli.

Trogulus nepæformis, Latreille.

Inhabits France and Germany, lurking under stones. It has not hitherto occurred in this country.

II. *Eyes placed on a common peduncle, very close together.*

Arachnides.

24. Phalangium.

Genus XXIV. Phalangium, *Linn. Fabr. Latr. Herm. Don.*; Opilio, *Herbst.*

Mouth consists of a labriform rostellum; two mandibulæ and palpi; six parts which appear to be maxillæ; a labium and sexual vagina.

Rostellum labriform, horny, short, conic, and inserted under the mandibules, above the maxillæ, in the middle of the origin of the palpi; the apex acuminated.

Mandibulæ porrect, horny, somewhat cylindrical, compressed, elongate, double-jointed, inflexed at the second joint, inserted under the middle of the interior margin, being longitudinally contiguous; the apex armed with a forceps; the chelæ conic and equal; the thumb or external chela moveable.

Palpi inserted at the base of the first maxillæ, under the origin of the mandibulæ; they are composed of five joints, which are nearly filiform, the third being excepted, which is cylindrical; the first very short, the second and last longer, the third shorter and nearly conic.

Maxillæ (organs resembling them in form) placed in a double order, closing the aperture of the mouth by meeting transversely; they are very short and membranaceous; the four upper ones vesicular and intumescent, with the base somewhat cylindrical and thickened; the apex rounded and hairy; a small, erect, conic, needle-like process at the base of the upper pair; the lowest pair narrow, elongate, lanceolate, and slightly connected together, arising from the origin of the second pair of feet, and resting on the apex of the sexual vagina.

Labium concealed by the maxillæ; on dissection it is quadrate and membranaceous, the apex being rounded, with the middle notched.

Vagina sexual, including the sexual organ of the male and oviduct of the female, is placed under the maxillæ, causing a prominence on the middle of the pectus, resembling a sternum.

Body somewhat orbicular or oval, covered by a soft semicoriaceous skin, the breadth rather exceeding the height.

Thorax semicircular, with a tubercle on the middle towards the hinder margin, on which the eyes are placed, one on each side.

Abdomen folded or wrinkled beneath.

Feet eight, very long and narrow; the second pair longest, then the fourth, next the third and first. The conæ composed of three, the tibiæ of two joints; the tarsi of several, the basilar or first one longest; nail small, horny, and bent, placed at the extreme apex.

* *The second pair of feet about six times longer than the body; all the tarsi hair-like; the inferior joints elongate, four times as broad as long.*

Opilio.

Sp. 1. *Opilio.* The eye-bearing tubercle with a double crown of little spines; body oval; thighs distinctly bearing spines disposed in many longitudinal series; back cinereous or testaceous, the middle of the abdomen blackish; the spines of the eye-bearing tubercle very conspicuous; eyes rather distant; the space of the thorax passing them not abruptly elevated; anterior tibiæ angulated (of the female with a groove); second joint of the palpi generally with a blackish or obscure spot.

Male, *Phalangium cornutum*, Lin. Fab. Hermann.

Female, *Phalangium opilio*, Linn. Fab. Hermann.

Inhabits Europe, is frequent on walls or amongst grass. The male has the second joint before the apex of the mandibles transversely and longitudinally fixed to the preceding; and palpi as long as the body. These sexual distinctions (which most probably apply to the whole genus) were observed by that celebrated observer of nature Geoffroy.

Observation 1. Latreille says, that he has observed a species much allied to *Phalangium opilio*, differing, however, by having the anterior feet nearly cylindrical, and not distinctly angulated, and the third and fourth joints of the palpi, especially the former, produced at the apex internally into a horn or branch, as in *Phalangium uncato* of Hermann, (*Mém. Aptér.* page 106, plate 8, fig. 5,); the second joint of the same colour with the rest; the upper part of the body somewhat nut-coloured, with paler spots; the back not black in the middle; the thighs less spiny. It appears to be nearly allied to Hermann's species above alluded to; the individual mentioned by Latreille was a female.

Observation 2. *Opilio longipes*, Herbst. (*Naturg. opil.* tab. 2. fig. 2.) is distinguished from *Phalangium opilio* by its pale nut-colour without the black dorsal mark; by the shorter spines of the eye-bearing tubercle; the eyes more approximated, reddish, with a black spot interposed; the space before them abruptly elevated; the second joint of the palpi of the same colour with the rest; the anterior tibiæ cylindrical and somewhat spinous. This is supposed to be a mere variety of *Phalangium opilio* by Hermann.

Observation 3. *Phalangium cornigerum* of Hermann, is readily distinguished from the male of *Phalangium opilio*, by its spiny palpi, the internal apex of the third and fourth joints prominent; the second joint of the mandibules before the apex near the chelæ elevated into a horn above. Latreille thinks this may be the male of *Phalangium uncatum.*

Sp. 2. *Rotundum.* The eye-bearing tubercle smooth and black; body orbicular-oval, above testaceous, the dorsum testaceous, that of the female with a black spot of a quadrate form, spotted with pale colour; base of mandibules with two teeth on the upper part; feet very slender and black, the extremities of the joints of the thighs and tibiæ generally whitish. Rotundum.

Phalangium rotundum, Hermann, Latreille.

Inhabits France, is common in a wood called St Germain, and at Petit-Gentilly. It has once occurred in Scotland, in Ravelston wood, near Edinburgh; it is probably rare in Britain.

** Second pair of feet three, four, or more times as long as the body; tarsi with the fourth, fifth, and following joints a little elongated, twice as broad as long.

Sp. 3. *Histrix.* The eye-bearing tubercle a little elevated, obscurely crowned with granulations; body quadrate-oval, the back cinereous or yellowish-grey; the coxæ and sides of the thorax spiny; the middle of the anterior margin itself, with three porrect close-set spines; feet pale yellowish, with obscure spots; the tibiæ angular; tarsi with thirty joints or more. Histrix.

Phalangium histrix of Hermann and Latreille.

Inhabits France and Britain; it is a common species, frequently occurring under stones, on walls, &c. The female has a quadrate black spot on its back. *Phalangium cristatum* of Olivier (*Encyclop. Méthodique*), and *Opilio hispidus* of Herbst. (tab. 3. fig. 1, 2.), belong to this division.

Sp. 4. *Quadridentatum.* The eye-bearing tubercle and base of the palpi and feet spiny; body oval, de- Quadridentatum.

Arachnides.

pressed, obscurely cinereous; the anterior middle of the anterior margin of the thorax with a strong elevated spine; the abdomen with a quadruple row or series of tubercles; the apex armed with four teeth; the tarsi of the second pair of feet with about seventeen joints.

Phalangium quadridentatum, Cuvier, Fabricius, Latreille.

Inhabits the south of France; is found under stones, and, according to Latreille, is rare in the environs of Paris.

Bimaculatum. *Sp.* 5. *Bimaculatum.* Body bluish-black, with two white spots; the tarsi somewhat clubbed at their extremities.

Phalangium bimaculatum, Fabricius, Donovan, Hermann.

Inhabits Europe. In this country it very frequently occurs under stones during the whole year; is more abundant in Scotland than in England.

25. Galeodes. Genus XXV. Galeodes, Oliv. Lam. Latr.; Phalangium, Pallas; Solpuga, Fab. Herbst.

Mouth provided with two mandibules and maxillæ, with palpi, and an under lip.

Palpi very large, feet-like and porrect, nearly as long as the hinder feet; filiform composed of five joints, inserted on the apex of the maxillæ; the first joint very short; the three following cylindrical, elongated; the third and second longer, especially the latter; the last very short, cylindrico-conical; the apex rounded, without a nail, and somewhat fleshy.

Mandibulæ horny and oval, externally convex, internally plain, bearing two chelæ, which are very bare and porrect; the chelæ more horny, very strong, and tooth-shaped, of the length of the mandibules, compressed; the apex very acute, arcuated, the internal side strongly toothed.

Maxillæ resembling coxæ, short, thick, and cylindrical, contiguous at their base, at which point they diverge; the internal angle at the apex lengthened into a little conic villose tooth.

Labium small, horny, compressed, and exserted between the maxillæ at the point at which they diverge; the apex bearing one tooth; the tooth evident, bent downwards; the anterior aspect of the lip bearing two small laciniæ, with two needle-like, moveable, vilose processes at their point.

Body elongate, soft, with the skin folded in rings.

Thorax having its anterior segment large, resembling a head, covered with a hard scutum of a triangular shape, broad before, truncated behind, on which the eyes are placed, the lower part bearing the mouth and anterior pair of feet.

Abdomen oblong-oval, with eight or nine folds.

Eyes four, placed on a transverse tubercle in the anterior part of the thorax; two larger, opposite, contiguous, and circle, with the pupil elevated and somewhat granular, the iris radiated; the other two very small, intermediate, below resembling stemmata.

Feet elongate and filiform (the anterior pair excepted), double or twins being transversely connected at their base; the tibiæ consisting of two elongate joints; the tarsi short, formed of two or three joints, the last with two filiform arched fingers, armed at their points with horny nails; the four anterior feet nearly equal and small; the third pair somewhat longer than the second; the fourth longest.

Observation. The upper part of the mandibules at the base of the chelæ bearing cirrhi; body villose; the palpi and feet bearing elongated hairs resembling spines, taking their origin from a glandular elevation. Latreille says this genus is called *Phax* by Hermann.

Araneoides. *Sp.* 1. *Araneoides.* Body pale yellow, mixed with ash-grey.

Phalangium araneoides, Pallas.
Solpuga araneoides, Fabr.
Solpuga arachnoides, Herbst.
Galeodes araneioides, Latreille.

Inhabits the Cape of Good Hope; a variety, or more probably a distinct species, nearly allied to this, occurs in Russia.

Family IX. Araneides.

The animals of this family are familiarly known under the general denomination of *Spiders,* and, as we have before mentioned, were included by Linné, Fabricius, and other authors, in one genus, which they called *Aranea.* As the species are very numerous, they were obliged to divide them into families, which were distinguished by the situation of their eyes, which in this family are generally eight (sometimes only six) in number, and are immoveable; they consist of but one lens, which deprives them of the faculty of multiplying objects, as their immobility does that of seeing them if placed otherwise than exactly before them; so that a number of eyes placed on different aspects, is essential to enable them to look on every side, to avoid danger and to see their prey.

As these animals are more interesting than any others in this class, we shall give our readers an account of their economy and habits, as given in the works of Dr Lister, Geoffroy, Reaumur, Dr Hulse, Lyoneret, Dr Mead, and others.

Spiders change their skin annually, and their skins are often found in their webs, being dry and transparent, having their mandibules attached to them. When about to cast their covering, they suspend themselves in some corner, and creep out at a crack which takes place on their back, gradually withdrawing their legs from the skin, as if it were a glove.

The webs of spiders are too well known to need much description: the mode of weaving these nets is however very interesting. For this purpose, they are provided with five teats or nipples at the extremity of their body, the apertures of which they can dilate or contract at pleasure. Through these holes they emit a gluey matter, which is contained in a bag communicating with the teats. They attach the end of their threads by applying their nipples to any substance, and the threads are lengthened as the animal recedes from it, and are immediately hardened from exposure to the air. They can stop the spinning by contracting the nipples, and can ascend the cord they have spun with wonderful facility. The mode of spinning peculiar to the different species, will be particularly noticed when treating of the animals themselves. Some species have the power of darting long threads to an immense distance, by means of which they can convey themselves across rivers or chasms, which has given rise to the vulgar notion of the flight of spiders. Dr Lister relates, that, attending minutely to a spider at work weaving its net, he observed it suddenly desist; and, turning its nipples to the wind, dart out a thread with the violence of a water jet: This thread, taken up by the wind, was carried to some fathoms length, still issuing from the body of the animal. Some time after the spider leapt into the air, and the thread mounted her up swiftly. He afterwards made the same observation on about thirty other species of spiders, and found the air filled with young and old sailing on their threads, and probably seizing insects in their passage, as he found legs and wings, and other manifest signs of slaughter, on those threads, as well as in the webs below. These observations were corroborated by Dr Hulse, who made the like discovery about the same time. It is Dr Lister's opinion, that this darting of threads was known to Aristotle and Pliny, (vide Aristotle, *Historia Animalium*, lib. ix. cap. 89. and *Plinius*, lib. x. cap. 74.); but believes their sailing was first observed by himself. On these sailing spiders he farther observes, that they will often dart not a single thread alone, but a whole sheaf at once, consisting of many filaments, all of one length, but divided from each other and distinct; and the longer they become, the more they spread, and appear like the numerous rays of a blazing star. He observed, too, that some species seemed to use their legs as oars, sometimes closing, and again spreading them out, as occasion might require. When the air is still, it is highly probable they can direct their course, and perhaps mount or descend at pleasure. In rowing, he observed they always take their flight backwards. These threads mount to an almost incredible height, and may always be observed in a fine clear day in autumn, when there is little or no wind. In a letter to Mr Ray, he farther observes, "that I one day observing the air full of webs, forthwith mounted to the top of the highest steeple on the minster (at York), and could there discern them exceedingly high above me." Thus have we briefly stated the observations of this celebrated naturalist, to which we may add his conclusions: They mount their threads upwards, and mount them in a line almost perpendicularly. This is not all; they also project them in a line parallel with the horizon, as may be seen by their threads running from one wall to another in a house, or from one tree to another in a field or garden. By what power this is done he does not attempt to show: It only, as he observes, "magnifies our ideas of that Being, who has given to so apparently contemptible an animal such vast powers for its maintenance and pleasure."

The apertures from which the web is produced are, according to Reaumur, very numerous. He says there are, in the compass of a pin's head, enough to yield an amazing number of distinct threads. These holes are perceived by their effects: Take a garden spider ready to deposit its eggs, and apply the finger to one of the papillæ or teats, and as you withdraw your finger, a vast many distinct threads will appear. Reaumur has often counted seventy or eighty by the assistance of a microscope; and perceived a vast many which he could not distinctly count. He says, that were he to say each teat has a thousand apertures, he should say too little. Each nipple is covered with minute prominences, and each of these probably has a vast number of openings; or between its several protuberances are holes, which give vent to threads: The use of these prominences may be to keep the threads asunder, at their first exit, before they are hardened by the air; and this is rendered very probable, as some spiders are provided with tufts of hair instead, which may serve the purpose of keeping the threads at a proper distance from one another. Leeuwenhoek has computed, that one hundred threads of a tolerably sized spider are not equal to the diameter of the hair of a man's beard, and, consequently, if the threads and hair be both round, ten thousand such threads are not larger than such a hair. And as young spiders (which are not, when first hatched, altogether as large as a single papillæ of the mother which produced them,) spin as soon as they quit the egg, he farther calculates, that as four hundred young ones are not larger than one full grown, four millions of their threads are not so thick as a hair of a man's beard. Some experiments have been made to manufacture the threads of spiders into silk; these we shall detail when their natural history is concluded.

The use of the webs above described, seems to be principally for the purpose of taking their prey, and defending them from the attacks of birds, some kinds constructing strong webs for that purpose. Their food, in every stage of their existence, consists of insects; nor do they spare their own species, preying on one another with the most savage ferocity. These inherent qualities create a disgust which even the expansion of philosophy will not always suppress. Thomson probably felt this sympathy of the mind, in his description of the spider:

" ——— To heedless flies the window proves
A constant death; where gloomily retired,
The villain spider lives, cunning and fierce,
Mixture abhorred! amid a mangled heap
Of carcases, in eager watch he sits,
O'er-looking all his waving snares around.
Near the dire cell, the dreadless wanderer oft
Passes, as oft the ruffian shews his front;
The prey at length ensnared, he dreadful darts
With rapid glide along the leaning line;
And fixing in the wretch his cruel fangs,
Strikes backwards grimly pleased; the flutt'ring wing,
And shriller sound, declare extreme distress,
And ask the helping hospitable hand."

The weapons with which they seize their prey, is a pair or sharp crooked claws or forceps placed in the front of the body. These they can open as occasion may require; when at rest, they lie one over the other. Leeuwenhoek says, that each of these claws has a small slit or aperture, through which a poisonous juice is injected into the wound they inflict. Dr Mead, in his *Essay on Poisons*, dissents from this altogether, having never been able, on repeated examinations, to discover any such opening, not even in the claws of the largest species. We have likewise investigated this point, and find that in many species there is a groove; but we are very confident it is nothing more, never having been able to discover any opening in the groove, after repeated examinations. Dr Mead says, that a small proboscis is thrust out of the mouth at the time the spider inflicts the wound, and infuses poison into it. Whether this be correct or not we shall not pretend to say, never having examined any of the large exotic species in a recent state; in our own species, nothing of the sort has hitherto occurred.

The part of generation of the male spider resides at the extremities of the palpi, which open, as it were, with a spring during the act of copulation; those of the female are situated under the abdomen. As these animals prey on each other except during the time of their amours, they dare not come within reach of one another but with the utmost caution. Some species may be observed, stretching out their legs, shaking the web, and tampering with one another by a slight touch with the extremity of their feet; then in a fright dropping down their thread and returning in a few minutes to make a fresh trial by feeling. When both parties are well assured of the sex they have to deal with, the approaches of their feet in order to feel are more frequent; confidence takes place, and amorous dalliance ensues. "We cannot," says Lyonnet, "but admire how careful they are not to give themselves up blindly to, or venture on, an imprudent step which might become fatal to them."

As to the employment of spiders threads in place of silk, Bon of Languedoc, about eighty years ago, made a pair of stockings and gloves from the threads of some species of spider; they were of a fine grey colour, and nearly as strong as those of common silk: on this discovery, he published a dissertation. Reaumur, who was appointed by the Royal Academy to examine into the merits and probable advantages which might arise from such a manufacture, urged the following objections and difficulties against it, which are published in the Memoirs of the Academy for the year 1710:—The natural fierceness of the spiders renders them unfit to be bred and kept together. Four or five thousand being distributed in cells, fifty in some, one or two hundred in others, the big ones soon killed and eat the smaller ones, so that in a short time there were scarcely above one or two left in each cell; and to this inclination of devouring their own species, he attributes the scarcity of spiders when compared with the vast number of eggs they lay. He affirms also, that the web of the spider is inferior in strength and lustre to that of the silk worm, and produces less of the material fit for use. The thread of the spider's web, he says, can only bear a weight of two grains without breaking; and the bag sustains the weight of thirty-six grains: the thread of a silk worm will bear two drams and an half, so that five threads of the spider are necessary to form a cord equal to that of a silk worm; as it would be impossible to apply these so closely together as to avoid leaving any empty space between from which the light would not be reflected, and consequently would throw out much less lustre: this was noticed at the time the stockings were presented to the society by M. de la Hire. He further remarks, that spiders afford less silk than silk worms: the largest bags of the latter weigh four grains, the smaller three grains; so that two thousand three hundred and four worms produce a pound of silk. The bags of a spider weigh about one grain; when cleared of the dust and filth they lose two thirds of that weight. The work of twelve spiders, therefore, only equals that of one silk-worm; and a pound of silk will require at least twenty-seven thousand six hundred and forty-eight spiders. But as the bags are solely the work of the females, who spin them to deposit their eggs in, there must be kept 55,296 spiders to yield one pound of silk; yet this will apply to the good ones only; those spiders in gardens most commonly scarcely yielding a twelfth part of the silk of the domestic kinds. Two hundred and eighty, it seems, would not produce more than one silk-worm; six hundred and sixty-three thousand, five hundred and fifty-five of them, would scarcely yield a pound.

From the above memoir it seems that the manufacture of silk from the European spiders would be attended with more trouble than profit; yet the webs of the large species inhabiting the tropics might probably be turned to good account, as we learn from Sir George Staunton's embassy to China, who, when speaking of the Java forests, says, "in some open spots were found webs of spiders even with threads of so strong a texture as not easily to be divided without a cutting instrument; they seemed to render feasible the idea of him who, in the southern provinces of Europe, proposed a manufactory of spider's threads, which was so very ridiculous to the eyes of those who have only viewed the flimsy webs such insects spin in England."

Having given an account of the animals which compose this family, as far as relates to their general history and economical uses, we shall proceed to define the genera, as given in the works of Walckenaer, Lamarck, and Latreille, the characters being deduced from the positions of the eyes, length of the different feet, figure and structure of the maxillæ, &c.; and when describing the species, we shall notice any peculiarities in their form, structure, or economy.

Their use in the economy of nature appears to be principally that of preventing the two great increase of other insects.

I. Feet not formed for leaping.

GENUS XXVI. MYGALE, *Latr. Walck.* ARANEA, *Lin. Fab. Lam. Oliv.* 26. MYGALE.

Labium very small and quadrate, inserted under the base of the maxillæ.

Palpi attached to the apex of the jaws.

A. The nails of the tarsus with few very obscure or no teeth on the under side.

* Mandibulæ without any apical rostellum; the under part of the last joint of the palpi and tarsi with a hairy scopula.

Sp. 1. *Avicularia.* Body covered with long and thick black hair; apex of the tarsi and feet rust coloured; tarsi broad; nails not exserted. Avicularia.

Aranea avicularia of Linné and Fabricius.

Aranea hirtipes, Fabricius, *Ent. Syst.* tom. ii. p. 420.

Mygale avicularia, Latreille, Walckenaer.

Inhabits South America, where it is well known under the names *Araignée aviculaire,* or *bird-catching spider.* Of its natural history we know nothing; it is the largest species discovered, being often found with a body as large, or even larger, than a goose's egg. It is said to spread a strong web between the trees in woods, in which it takes small birds as well as insects. The male's parts of generation are globose.

Sp. 2. *Cancerides.* Brown and hairy, the under part of the abdomen, with the breast, blackish. Cancerides.

Mygale cancerides, Latreille.

Inhabits the island of St Domingo, where it is called *araignée-crabe.* The genitalia of the male are produced into a horny-arched nail, the apex compressed, the foot-stalk a little longer than in the foregoing species.

Sp. 3. *Blondii.* Covered with rust-coloured hair; the basilar joint of the tarsi (especially of the posterior feet) with visible black spines. Blondii.

Inhabits Cayenne.

Mygale Blondii, Latreille.

Mygale de la Blond, Walckenaer.

Described and figured in the genera *Crustaceorum et Insectorum* of Latreille, (vol. i. tab. 5. fig. 1.) and in Walckenaer's work, p. 4. The genitalia of the male are somewhat conic and thick, the apex laterally excavated.

Sp. 4. *Fasciata.* Abdomen with a broad greyish longitudinal band, with the margins notched or sinuated. Fasciata.

Arachnides.

Mygale faciata, Latreille.

Mygale faciée, Walckenaer, p. 4.

Said by Seba, who has given a figure of this species, (tom. i. tab. 69. fig. 1.), to be a native of Ceylon.

** Apex of the mandibulæ furnished with a rostellum; palpi and tarsi without any scopa.

Cæmentaria. *Sp.* 5. *Cæmentaria.* Rusty brown coloured; mandibules blackish, the border and carina of the thorax paler; each rostellum with five elongate nearly equal teeth.

Mygale cæmentaria, Latreille.

Mygale maconne, Walckenaer, p. 5.

Inhabits the South of France. See *Linnean Transactions,* vol. ii. pl. 17. fig. 4.

Sauvegesii. *Sp.* 6. *Sauvegesii.* Obscure-brown; each rostellum with four short unequal teeth.

Aranea Sauvagesii, Rossi (*Fauna Etruscana,* tom. ii. tab. 9. fig. 11.)

Mygale pionnière, Walckenaer, p. 5.

Mygale Sauvegesii, Latreille.

Inhabits Corsica and Italy.

B. Nails of the tarsi armed with toothed combs below.

Calpeiana. *Sp.* 7. *Calpeiana.* Brownish colour.

Mygale calpeiène, Walckenaer, p. 5.

Mygale calpeiana, Latreille.

Inhabits France.

To this division of the genus belong also *Mygale notasiana* of Walckenaer.

27. Atypus. GENUS XXVII. ATYPUS, *Latr.* OLETERA, *Walck.* ARANEA, *Ræm.*

Lip very small and quadrate, inserted under the base of the maxillæ.

Palpi inserted at the external base of the maxillæ.

Sulzeri. *Sp.* 1. *Sulzeri.* Black and shining; mandibulæ very strong; thorax nearly quadrate; plain behind, abruptly elevated before; the two middle eyes placed on an eminence; back of the abdomen leathery or coriaceous, and more shining; the juncture of the joints of the feet white.

Oletère difforme, Walckenaer, p. 7.

Atypus sulzeri, Latreille. (*Gener. Crust. et Ins.* vol. i. tab. 5. fig. 2.)

Inhabits France; has been once found in England by Mr Leach, who still has the specimen in his possession, although in a very mutilated state.* It was first described by Latreille in the *Nouveau Dictionnaire d'Hist. Nat.* tom. xxiv. table page 133. under the name *Atype,* which having the right of priority over that given by Walckenaer, we have retained.

28. Eriodon. GENUS XXVIII. ERIODON, *Latr.* MISSULENA, *Walck.*

Lip linear exserted between the maxillæ.

Palpi inserted as in the genus *Atypus.*

Occatorius. *Sp.* 1. *Occatorius.* Colour unknown.

Eriodon occatorius, Latreille.

Missulène herseuse, Walckenaer.

29 Segestria. GENUS XXIX. SEGESTRIA, *Latr. Walck.* ARANEA, *Linn. Fab. Rossi.*

Maxillæ straight, longitudinal, with the base thickened, dilated externally, somewhat wedge-shaped, the middle longitudinally convex.

Lip elongate-quadrate, longer than broad, the middle longitudinally convex, and somewhat carinated.

Feet, the first pair longest, next in order the second, then the fourth; the third pair being shortest.

Cellaria. *Sp.* 1. *Cellaria.* Brownish-black, obscurely cinereous-silky; mandibules green; the breast and base of the feet brown.

Aranea florentina, Rossi. (*Fn. Etrus.* tom. ii. p. 133. tab. 9. fig. 3.)

Segestria perfida, Walckenaer, p. 48.

Segestria cellaria, Latreille.

Inhabits fissures in old buildings and rocks, spinning a silky tube. The genitalia of the male resemble those of *Mygale avicularia.*

It is not uncommon in France and Italy; but in this country it seems to be rare, only one specimen, we believe, having been met with, which was taken by a dealer in natural curiosities in a cellar at Plymouth, and is now preserved in the collection of Mr Leach.

Senoculata. *Sp.* 2. *Senoculata.* Thorax blackish brown; abdomen oblong, grey, with a longitudinal band of black spots; feet light brown, with obscure fasciæ.

Aranea senoculata, Linn. Fabr.

Segestrie senoculee, Walckenaer, p. 48; Fourcroy.

Segestria senoculata, Latreille.

Is found in the same situations as the last species. A good figure is given in Lister's work on British spiders, p. 74. titul. 24. fig. 24. It has been bred from the egg by Mr Leach, who observed a very curious fact in the colour of this animal, viz. the bands on the feet are much more distinct in the young than in the full grown animal, so much so, indeed, that had he not known the eggs to have been deposited by this species, would probably have considered it as a very distinct species; but having an opportunity of rearing them to the full size, all doubts on the subject vanished.

30. Dysdera. GENUS XXX. DYSDERA, *Latreille, Walckenaer.* ARANEA, *Fourcroy.*

Maxillæ straight, longitudinal, with the base thickened; externally dilated at the insertion of the palpi; the apex internally obliquely truncated, and thence externally acutely terminated.

Palpi with the first joint very short and nearly obsolete.

Lip, elongate, quadrate, gradually narrowing towards the point.

Feet, first pair, then the fourth, afterwards the second, longest; the third pair shortest: a little scopula under the tarsal nails.

Erythrina. *Sp.* 1. *Erythrina.* Mandibules and thorax blood-red; the feet lighter coloured; abdomen very soft, greyish yellow, and silky.

Aranea erythrina, Fourcroy, *Fauna Parisiensis,* tom. ii. p. 224.

Drysdere éythrine, Walckenaer, p. 47.

Drysdera erythrina, Latreille, *Genera Crust. et Ins.* tom. i. tab. 5.

Inhabits France and England under stones. It is not common in this country; it has been observed by Mr Leach near Exeter and London, four or five times. *Aranea hombergii* of Scopoli (*Entomologia Carniolica,* No. 1119.) is merely a variety of this species.

Observation. To this genus, *Aranea rufipes* of Fabricius, (*Entomologia Systematica,* tom. ii. p. 426.), seem to belong, as appears from his description: "Head and thorax obscurely ferrugineous, and immaculate, eyes six, placed near together; abdomen ovate, cinereous immaculate. Feet bright red."—"Inhabits Morocco." Latreille supposes this may be even the same species with *erythrina,* as we are unacquainted with the Fa-

* Two other specimens have been since taken, one by Mr Standitch of Walworth, the other by Mr Tuther, optician, London.

Arachnides.

brician *aranea rufipes*, we cannot but hesitate on giving any thing like a decided opinion.

31. Filistata.

Genus XXXI. Filistata, *Latreille.*

Eyes placed on an uneven elevation; the four anterior ones forming a semicircle opened in front; the four hinder ones disposed in pairs in nearly the same transverse straight line.

Maxillæ much inclined towards the lip, with no sinus or groove at the insertion of the palpi.

Palpi apparently inserted on the hinder side.

Lip much longer than broad.

Feet, the fourth pair longest, and then the first pair.

Observation. This genus contains one species, *Filistata testacea* of Walckenaer's MSS. of which we have no description; it has lately been discovered in the environs of Marseilles.

32. Drassus.

Genus XXXII. Drassus, *Walck. Latr.* Aranea, *Linn.* Gnaphosa, *Latr.*

Palpi inserted under the lateral and external margin of the maxillæ towards the middle.

Maxillæ longitudinal, arcuated, gradually becoming broader from the base towards the middle, somewhat concave internally, smooth exteriorly, the middle impressed, the points bent inwards above the lip, and obliquely truncated within.

Lip elongate, ovate-quadrate, or rather oval, the base transversely truncated, enclosing the maxillæ.

Feet, the fourth, then the first, and afterwards the second pair longest.

* Lip somewhat oval; the external side of the maxillæ much bent or arched.

Melanogaster.

Sp. 1. *Melanogaster.* Mandibules blackish; thorax and feet obscure brown, thighs light reddish brown; abdomen cinereous-brown and silky.

Drassus melanogaster, Latreille.

Drasse lucifuge, Walckenaer, p. 45.

Inhabits the South of France, under stones.

** Lip ovate quadrate.

Fuscus.

Sp. 2. *Fuscus.* Obscure reddish-brown, silky, the abdomen blackish mouse coloured.

Drassus fuscus, Latreille.

Inhabits the South of France, of the same size with the other species.

Ater.

Sp. 3. *Ater.* Entirely black.

Drassus ater, Latreille.

A small species, frequently occuring in the vicinity of Paris, under stones, to which it adheres pretty firmly; when first hatched they are of a reddish colour.

Relucens.

Sp. 4. *Relucens.* Red, very smooth, like purple velvet; abdomen black, with two transverse golden yellow lines.

Drasse brillant, Walckenaer, p. 46.

Drassus relucens, Latreille.

Common in the south of France; it sometimes occurs in the neighbourhood of Paris.

33. Clotho.

Genus XXXIII. Clotho, *Walckenaer's MSS.*; *Latreille.*

Maxillæ much inclined towards the lip, with no groove at the insertion of the palpi.

Lip not much longer than broad.

Feet, fourth pair, the second, the third longest.

Eyes close together, disposed four and four in two lines bent backward in an arched and somewhat concentric manner; those in the hinder line disposed in pairs.

Observation. This genus contains but one species described in the manuscripts of Walckenaer, who communicated the generic character to Latreille, who has published it in his last work, entitled, "*Considérations générales sur l'ordre naturel des Crustacés, des Arachnides et des Insectes.*"

Durandii.

Sp. 1. *Durandii.* Thorax rusty brown, margined with pale yellow; abdomen black, with five red spots, arranged 2, 2, 1; feet livid brown.

Inhabits Montpellier, building its web amongst the stones.

Clotho durandii, Latreille.

34. Clubiona.

Genus XXXIV. Clubiona, *Latreille, Walckenaer.* Aranea, *Linné, De Geer.*

Maxillæ straight and longitudinal; the basis a little dilated externally; the apex rounded and obliquely truncated on the inside.

Lip elongate, quadrate, gradually narrowing towards the point.

Feet, the first, and then the fourth pair, (or the contrary), longest; then the second pair.

* The two outermost eyes on either side neither placed very close together, nor inserted on a distinct prominence. The maxilla in all with an incrassated base; the fourth pair of feet (rarely the first) longest.

Lapidicola.

Sp. 1. *Lapidicola.* Thorax and mandibules pale reddish; feet very light red; abdomen ash-grey coloured.

Clubione lapidicole, Walckenaer, p. 44.

Clubiona lapidicola, Latreille.

Inhabits France and Britain under stones, constructing a somewhat globular nest of the size of a common hazel nut, in the centre of which are deposited a vast number of pale yellowish eggs, agglutinated into a spherical mass.

The mandibules of the *male* porrect, and rather more than half the length of the thorax; those of the female somewhat vertical.

Tholocericea.

Sp. 2. *Tholocericea.* Mandibules blackish; thorax pale livid green; abdomen reddish-black, covered with mouse-coloured down; feet lighter than the thorax, the fourth pair longest.

Clubione soyeuse, Walckenaer, p. 42.

Clubiona holosericea, Latreille.

Aranea holosericea, Linné.

Araignée satinée, De Geer.

Inhabits Europe, getting under the bark of trees. The four anterior feet nearly of the same size.

Observation. From the position of the eyes it is probable that *Cubiona accentuata* of Walckenaer belongs to this family. From his figure, the anterior, and then the fourth pair of feet, are longest.

** The two external eyes on each side somewhat placed close together. (Maxillæ not thickened at their base; the first and then the second pair of feet longest.)

A. Maxillæ somewhat thickened at their base, and transversely impressed before the middle.

Nutrix.

Sp. 3. *Nutrix.* Ungulæ black; thorax and mandibules light red; feet very light red; abdomen yellowish green, with an obscure longitudinal band.

Clubione nourrice, Walckenaer, p. 43.

Clubiona nutrix, Latreille.

Inhabits the environs of Paris; common in a place called *Sévres*, building a nest amongst the leaves of the *Eryngium campestre.* The mandibulæ of the male stronger than those of the female.

B. Maxillæ not at all thickened at their base; front not transversely impressed.

Atrox.

Sp. 4. *Atrox.* Brown; feet pale; the tibiæ with more obscure or dark spots; the middle of the back of the abdomen with a somewhat quadrate black spot margined with yellow.

Arachnides.

Clubione atroce, Walckenaer.
Araignée atroce, De Geer.
Clubiona atron, Latreille.

Inhabits old walls and fissures of rocks. Is very common in Britain and France. A tolerable figure is given in the work of Dr Lister, in the British spiders, p. 68. fig. 21.

35. Aranea.

Genus XXXV. Aranea. *Linn. Geoff. De Geer. Fabr. Oliv. Lam.*

Maxillæ straight and longitudinal; diameters equal; anterior part convex; apex rounded, the internal angle truncated.

Lip nearly quadrate; diameters nearly equal, towards the superior angles a little narrower.

Feet, the anterior longest and nearly equal, the third shortest.

* Internal angle of the apex of the maxillæ truncated; breadth and length of the lip nearly the same; the feet of a moderate length.

Obs. The series of eyes, especially the lower, more arched in this than in the second division of the genus.

Genus Agelena of Walckenaer.

Labyrinthica.

Sp. 1. *Labyrinthica.* Pale grey, inclining to red; the thorax on each side with a longitudinal black line; abdomen black, above and on each side with oblique white lines, meeting together by pairs at obtuse angles in front; the spinning papillæ conic and lengthened.

Aranea labyrinthica. Linné, Fabricius, Latreille.
Agelena labyrinthica. Walckenaer.
Agelène labyrinthe. Walckenaer, page 51.

Inhabits Europe; is very abundant in summer, more so in autumn: it spins a horizontal web in the ground, in which it watches for its prey, which consist principally of flies and other dipterous insects; the spider itself living in a funnel-shaped cavity, often extending below the surface of the ground. There are good figures in the works of Lister (page 60. fig. 18.) and in Schæffer's *Icones Insectorum,* (tab. 221. fig. 12.; tab. 19. fig. 8.)

** Internal angle of the maxillæ at the apex evidently truncated. Lip longer than broad. Feet elongated.

Genus Tegeneria of Walckenaer.

Domestica.

Sp. 2. *Domestica.* Livid grey; the thorax of the male immaculate; of the female with a longitudinal blackish line on each side; abdomen blackish, the dorsum in the middle with a longitudinal fascia or band, spotted, toothed with two lateral livid lines.

Aranea domestica. Linné, Fabricius, Latreille.
Araignée domestique. De Geer, Latreille.
Tegeneria domestica. Walckenaer.
Tégénaire domestique. Walckenaer, page 49.

Inhabits the houses of Europe; spinning its web in a place where there is a cavity, such as the corner of a room, that she may have a free passage, on each side, to make her escape in case of danger. Her mode of constructing her web is curious: having chosen a convenient spot, she fixes one end of her thread to the wall, and passes on to the other side, dragging the thread along with her, (or rather the thread follows her as she proceeds,) till she arrives at the other side, and there fixes the other end of it. Thus she passes and repasses, till she has made as many parallel threads as she thinks necessary for the purpose. After this she begins again, and crosses these by other parallel threads. These are the toils or snares which she prepares for entangling flies and other small insects. Besides this large web, she weaves a cell for herself, where she lies concealed, watching her prey. Between this cell and the net she has a bridge of threads, which, by communicating with the threads of the large one, both gives her intelligence when any thing touches the web, and enables her to pass quickly in order to lay hold of it.

36. Argyroneta.

Genus XXXVI. Argyroneta, *Latreille, Walck.* Aranea, *Linn. Geoff. Fabr.*

Maxillæ short, straight, and elongate-quadrate, the side of nearly equal diameters; face convex before, apex rounded.

Lip short; shorter than the maxillæ, of a narrow elongate-triangular or (somewhat conic) form; the anterior aspect convex, the apex either obtuse or truncated.

Feet, the first, the fourth, and lastly the second pair longest.

Obs. The sexual distinctions are the same in this genus as in the Clubionæ.

Aquatica.

Sp. 1. *Aquatica.* Blackish-brown; the abdomen black and velvety, impressed with dorsal punctures.

Aranea aquatica. Linné, Fabricius.
Argyronéte aquatique. Walckenaer.
Argyroneta aquatica. Latreille.
Araignée aquatique. De Geer.

Inhabits fresh waters, that flow slowly, throughout Europe. It resides in a web most beautifully constructed under the water, in which it lives, being surrounded by air, which shines through the water with a silvery lustre. The eggs are deposited in a globose silky bag. In Britain it appears to be of very rare occurrence, only having been taken once, if we recollect rightly, near Hornsey. This specimen is preserved in the collection of our great and illustrious zoologist, Edward Donovan, Esq.

37. Scytodes.

Genus XXXVII. Scytodes. *Latreille, Walckenaer.*

Maxillæ oblique and longitudinal, covering the sides of the lip; the base thickened, the apex internally obliquely truncated.

Lip somewhat quadrate, the base a little contracted.

Feet, the fourth, then the first, lastly the second pair longest.

Thoracica.

Sp. 1. *Thoracica.* Pale reddish white, spotted with black; thorax large and somewhat orbicular, elevated roundly behind; abdomen lighter coloured, and somewhat globose.

Scytode thoracique. Walckenaer, page 79.
Scytodes thoracica. Latreille.

Inhabits houses in Paris. Is figured in the *Genera Crustaceorum et Insectorum* of Latreille, (tab. 5. fig. 4.)

38. Theridion.

Genus XXXVIII. Theridion, *Latreille.* Aranea, *Linn. Geoff. Fabr.*

Maxillæ with an oblique direction, covering the sides of the lip, converging towards the apex, from the insertion of the palpi to the apex of an equal breadth and plain, the internal apex either obliquely truncated or obtuse.

Lip small, triangular or semicircular, the apex truncated, or somewhat rounded, or somewhat square.

Feet elongate, very slender; the first, then the fourth, then the hinder ones longer.

* Two of the eyes close together on each side.

Genus Theridion of Walckenaer.

Rufum.

Sp. 1. *Rufum.* Abdomen globose, the upper part radiated with white lines

Théridion Sisiphe. Walckenaer.

Arachnides.

Theridion Sisiphum. Latreille.

Inhabits Europe, nidificating under the prominences of pillars, or projections of walls.

Redimitum. *Sp.* 2. *Redimitum.* Yellowish white; abdomen oval, with a rose-coloured dorsal ring.

Aranea redimita. Linné.

Theridion couronné. Walckenaer.

Theridion redimitum. Latreille.

Inhabits plants. Abdomen often spotted. Latreille supposes *Theridion ovatum* of Walckenaer to be no more than a variety of this species; and that the *l'araignée à bande rouge* of Geoffray, (*Hist. des Insect.* tom. ii. page 648) is referable to the same variety.

** The two lateral eyes at a distance from each other.

Genus LATRODECTUS of Walckenaer.

Obs. Walckenaer has examined the eyes, maxillæ, and lip of the THERIDIONA, with the most minute attention. In his last work, Latreille has admitted the genus LATRODECTUS as distinct from THERIDION, and given the following characters; but as we are not acquainted with the genus LATRODECTUS, the reader must judge for himself.

LATRODECTUS. The first and then the second pair of feet longest; eyes disposed, four and four, in two transverse straight parallel lines.

THERIDION. The first and then the fourth pair of feet longest; the four middle eyes disposed in a square, the lower ones situated on a common prominence; two others close together, and placed in an eminence on each side.

From the above characters it would seem they are very distinct genera, but a letter on the subject we have received from a friend, informs us that he is well acquainted with the animal's economy, and that it ought to remain where Latreille placed it, in the first instance, at least for the present, as our knowledge of the subject is at present too limited for us to make two minute divisions; on this ground, therefore, we continue it under the generic title of THERIDION.

Tredium-guttatum. *Sp.* 3. *Tredium-guttatum.* Black; abdomen globose, with thirteen blood-red spots.

Aranea 13-guttata of Rossi and Fabricius.

Latrodecte malmignatte. Walckenaer, page 81.

Theridion 13-guttatum. Latreille (*Gen. Crust. et Ins.* i. p. 98.

Latrodectus 13-guttatus. Latreille. (*Consid. Ord. Nat.* &c.)

Inhabits Italy, and is common in the plains of that country.

39. Pholcus. GENUS XXXIX. PHOLCUS, *Walck. Latr.* ARANEA, *Geoff. Scopoli.*

Maxillæ oblique, covering the sides of the lip, converging from the base to the apex; apex internally truncated.

Lip transversely quadrate, the lateral angles at the apex rounded and somewhat marginated.

Feet very long and slender, the first longest, then the second, and then the fourth nearly equal.

Phalangioides. *Sp.* 1. *Phalangioides.* Pale livid; abdomen elongate; very soft, of a cylindrical oval form, and obscure grey colour; the apex of the tibiæ and thighs with a whitish, pale anulus or ring.

Pholcus phalangiste. Walckenaer, page 80.

Aranea pluchii. Scopoli.

Aranea phalangioides. Fourcroy. (*Entomologia Paris,* ii. 213.)

Pholcus phalangioides. Latreille.

Inhabits the European houses; its body vibrates after the manner of TIPULARIÆ, or *gnats.* Is very common in the west of England.

GENUS XL. ULOBORUS. Latreille. 40. Uloborus.

Eyes eight, equal and very minute, placed in two transverse lines, the first nearly straight, and scarcely bent backwards; the two middle ones a little nearer than the others; the posterior line bent forwards.

Maxillæ straight, broad, inversely triagonal, the side broader than the apex.

Lip very small and semicircular.

Feet, first pair much the largest, then the fourth, and afterwards the second.

Sp. 1. *Walckenaerius.* Pale reddish yellow; thorax and abdomen silky; the back white; abdomen oblong, banded with fasciculi of hairs; feet also banded with darker rings. Walckenaerius.

Inhabits the pines in Germany and France, where it constructs a web like that of *Lyniphya triangularis.*

GENUS XLI. TETRAGNATHA, *Latr. Walck.* ARANEA. *Linn. Fab. Oliv.* 41. Tetragnatha.

Maxillæ straight, elongate and narrow; almost as broad as long; the apex externally dilated and rounded.

Lip semicircular and somewhat notched.

Feet very long and very slender; the first pair, then the second, and then the fourth longest.

Sp. 1. *Extensa.* Reddish; abdomen oblong, golden green, with the sides and two lines below yellowish; the middle below longitudinally black. Extensa.

Aranea extensa. Linné, Fabricius.

Tetragnathe etendue, Walckenaer, p. 68.

Tétragnatha extensa. Latreille.

Inhabits moist places in Europe; it spins a vertical web, and remains with its feet extended, the anterior ones porrected.

GENUS XLII. ZINYPHIA, *Latr. Walck.* ARANEA, *Linn. De Geer.* 42. Zinyphia.

Maxillæ nearly straight, inversely—somewhat oval.

Lip semicircular.

Feet elongate and slender; the first, then the second, afterwards the fourth pair longest.

Sp. 1. *Triangularis.* Pale reddish, inclining to yellow; thorax with a black dorsal line, bifid in front; abdomen oval, inclining to globose, with spots and angulated bands of brown and white; feet immaculate. Triangularis.

Linyphie triangulaire. Walck. page 70.

Linyphia triangularis. Latreille.

Inhabits the European hedges; is common in Autumn, building its nest on pines, ferns, and genistæ.

GENUS XLIII. EPEIRA, *Walck. Latr.* ARANEA, *Linn. Fab. Lam. Donovan.* 43. Epeira.

Maxillæ nearly straight, their base narrow, their apex widened; the base internally concave; the apex above the lip incurved, and obliquely truncated.

Lip semicircular, and somewhat margined.

Feet elongate and slender; the first pair longest, then the second, afterwards the fourth; the third very short.

* *Thorax* an oblong oval, inclining to quadrate; the lateral *eyes* placed on a tubercle; *abdomen* coriaceous, and spinous above; or soft, much lengthened and cylindrical, and rounded at the base and apex.

A. Abdomen coriaceous or spiny above; the anus below prominent and tubular.

a. Abdomen nearly triangular, extended in length.

Arachnides.

Armata. *Sp.* 1. *Armata.* Abdomen depressed and punctate, with four spines; the two lateral ones very short; the others very long and crooked.

Aranea taurus, Fabricius. *Epëira armata*, Latr.
Inhabits the island St Domingo.

Aculeata. *Sp.* 2. *Aculeata.* Black; abdomen with eight spines; six on the back; two very small, and horizontal at the base; three on each side, marginal and erect; the hinder two large and red, with blackish points, with two inferior ones at their base; thighs rough with spines.

Epëira armée, Walck. p. 65. *Aranea aculeata*, Fabr.
Inhabits Cayenne.

b. Abdomen extended in breadth.

Cancriformis. *Sp.* 3. *Cancriformis.* Abdomen transversely oval and depressed; the superior margin (or ambitus) with six teeth; the teeth equal, two on each side, and two behind.

Aranea cancriformis, Linné, Fabricius. *Epëira cancriformis*, Latreille.

Inhabits the American islands. A good figure may be found in Brown's *Hist. of Jamaica*, p. 419, pl. 44, fig. 5.

B. Abdomen soft, without spines; generally elongated, and somewhat cylindrical, rounded at the base and apex; thorax with two dorsal tubercles. The tibia, the third excepted, generally covered with tufts of hair.

Clavipes. *Sp.* 4. *Clavipes.* Thorax black, covered with silver-coloured silky down, on which are black spots; abdomen obscurely yellowish, with white spots; the mouth, the greater part of the breast, and feet, pale-reddish. All the tibiæ, except the third pair, with tufts of hair.

Aranea clavipes, Linné, Fabr. *Epëira clavipes*, Latr.
Inhabits South America.

** *Thorax* somewhat heart-shaped, not half as long again as broad; the anterior margin much narrower than the greatest breadth.

A. Anterior part of the thorax depressed and flat; the sides abruptly sloping at nearly right angles.

a. The lateral eyes somewhat geminated; the anterior margin of the thorax at least half the breadth of the broadest part.

Sexcuspidata. *Sp.* 5. *Sexcuspidata.* Brown; thorax with six tubercles placed in a double transverse series; the three anterior ones bearing eyes; palpi, tibiæ, and tarsi, compressed.

Aranea sexcuspidata, Fabr. *Epëire impériale*, Walck. p. 67. *Epëira sexcuspidata*, Latreille.
Inhabits the Cape of Good Hope.

Umbratica. *Sp.* 6. *Umbratica.* The mandibules, hinder part of the thorax, under part of the body, and greater part of the thighs, black; anterior part of the thorax, with the tibiæ and tarsi, greyish-red; the tibiæ annulated with black; abdomen depressed, triangular oval, obscurely reddish-grey, with six or eight cicatrized black dorsal spots, placed in a double longitudinal series, with two undulating lines marginated with pale, one on each side, conjoining behind.

Aranea umbratica, Villers. *Epëire ombraticole*, Walck. p. 61. *Epëira umbraticola*, Latreille.

Inhabits Europe, being most frequently found in shady groves. The base of the mandibules elevated; the interior margin of the thorax broader than in the other species of this subdivision.

Diadema. *Sp.* 7. *Diadema.* Reddish; abdomen globosely, oval, the base on each side with an elevated angle; the back with a broad, dentated, triangular, obscure mark, and a triple cross formed of yellowish white spots; the four middle ones impressed and disposed in a quadrangle.

Aranea diadema, Linné, Fabricius, Donovan, Shaw. *Epeire diadème*, Walck. p. 58. *Epeira diadema*, Latr.
Inhabits Europe; is very common in gardens.

b. The lateral *eyes* somewhat geminated. The anterior margin of the *thorax* about a third part of the breadth of the broadest part.

1. Sides of the abdomen entire.

Fasciata. *Sp.* 8. *Fasciata.* Thorax and base of the abdomen above silvery; abdomen ovate, with yellow bands and black transverse lines.

Aranea fasciata, Fabr. *Aranea formosa*, Villers. *Aranea phragmitis*, Rossi. *Epeire fasciée*, Walck. p. 55. *Epeira faciata*, Latr.

Inhabits the south of Europe; is found in France, Italy, Sweden, and has been received from Madeira, where it was first observed by a lady of eminent abilities.

2. Sides of the abdomen notched.

Sericea. *Sp.* 9. *Sericea.* Body silvery; feet reddish, annulated with black and red.

Epèire soyeuse, Walck. p. 56. *Epèira sericea*, Latr.
Inhabits the south of France and Africa.

B. Anterior part of the thorax convex; the sides gradually sloping away.

a. The distance between the lateral and four middle eyes, much greater than the breadth of the quadrangle, formed by these four eyes.

Cucurbitina. *Sp.* 10. *Cucurbitina.* Abdomen globose, of a yellow green colour, somewhat spotted with black; a red spot behind.

Aranea cucurbitina, Linné. *Epèire cucurbitine*, Walck. *Epeira cucurbitina*, Latr.
Inhabits plants in Europe.

b. The distance from the lateral to the four middle eyes about the same as the breadth of the quadrangle formed by the four middle eyes.

Calophylla. *Sp.* 11. *Calophylla.* Thorax and feet pale livid yellow; the mandibules a triagonal spot on the anterior part of the thorax, and spots on the feet blackish; abdomen globose-oval cinereous-grey; back with four impressed spots; and a large silvery-grey oval spot, truncated behind, sinuated laterally, with the margins and a spot on each side in front of the abdomen, with a double line on the breast, and a longitudinal band in the middle of the belly black; sides of the breast with a yellow line.

Epèire calophylle, Walck. p. 62. *Epeira calophylla*, Latr.
Inhabits the eaves of houses; is common in Paris.

Menardi. *Sp.* 12. *Menardi.* Livid reddish; hinder part of the thorax deeply impressed with a dorsal line, bifid before, of a brown colour; abdomen globosely oval, of a darker colour; the back, the middle of the belly, and two lines on each side, light yellow; the dorsal space intersected behind by transverse bands anteriorly, with two oblong blackish spots; feet with dark rings.

Epèire brun, Walckenaer. *Epeira menardi*, Latr.

Conica. *Sp.* 13. *Conica.* The lateral and inferior middle eyes resting on a common tubercle; thorax black; abdomen ovate, of a reddish grey colour, with spots and reticulated black lines, the hinder part above and below protruded into a conic process; feet pale yellow, knees reddish.

Epèire conique, Walck. *Epeira conica*, Latr. *Araignée à ventre conique*, De Geer.

Inhabits the European woods; is common in Britain.

45. Episinus. GENUS XLV. EPISINUS, *Walckenaer's MSS. Latr.*

Maxillæ straight and longitudinal, the base a little dilated, the apex rounded.

Lip much broader than long, and semicircular.

Feet much lengthened; the anterior and then the fourth pair longest; the third shorter.

Eyes forming the segment of a circle, of nearly an equal size, placed on an eminence.

Observation. We have introduced this genus on the authority of Latreille, who copied his character from the

Arachnides. manuscripts of his friend Walckenaer; it contains but one species, *Episenus truncatus*.

Truncatus. *Sp.* 1. *Truncatus.* Thorax cordiform, a little longer than broad, anteriorly acute, little, above of an obscure reddish brown; the breast reddish brown; the abdomen brown, pyramidal, marginated in front; the dorsal area three-sided, with the hinder angles produced; the third pair of feet white, the others brown; the apex of the first and fourth, and base of the latter, white.

46. Micrommata. GENUS XLVI. MICROMMATA, *Latreille*. ARANEA, *De Geer, Fabr.* SPARASSUS, *Walckenaer*.

Maxillæ straight, oval inclining to square, with a longitudinal angle on their inside; the internal edge at the base somewhat concave; the apex obliquely truncated.

Lip short and semicircular.

Feet elongate; the fourth longest, the second rather shorter; then the first, afterwards the third. Lower part of the apex of the tarsi furnished with a little double brush.

Smaragdina. *Sp.* 1. *Smaragdina.* Bright green; dorsum of the abdomen with a longitudinal band of a darker colour.

Aranea smaragdula, Fabr. *Araignée toute-verte*, De Geer. *Sparasse émerandine*, Walck. p. 39. *Micrommata smaragdina*, Latr.

Inhabits the European woods and groves. The male has three longitudinal red lines on its back.

Observation. The genus was first established by Latreille under the name *Micrommate*, in the *Nouv. Diction. d'Hist. Natur.* tom. 24. p. 135. in which work also a figure is given; on this account we have retained it, and have consequently rejected the term *Sparassus* of Walckenaer, Latreille's name having the right of priority.

47. Thomisus. GENUS XLVII. THOMISUS, *Walck. Latr.* ARANEA, *Lin. Fab. De Geer.*

Maxillæ oblique, covering the sides of the lip, and in some degree converging; the internal apex truncated.

Lip somewhat oval, or nearly quadrate, generally longer than broad.

Feet, the first and second pair longest; the latter rather longer than former or scarcely shorter; the third and fourth generally much less; sometimes one longer, sometimes the other.

Observation. The mandibulæ are either perpendicular or somewhat inflexed, in many conical, with very short nails. Latreille formerly included this genus under the titles *Heteropoda* and *Misumena*.

** Thorax convex and heart-shaped; the sides, especially behind, abruptly sloping, anteriorly broadly truncated; the largest feet not double the length of the body; the first and second pair of the same magnitude as the rest, but far exceeding them in thickness (sometimes one sometimes the other longer.) The first joint of the tarsi with several moveable little spines, in a single or double series; the nails of all the tarsi naked. Lip somewhat oval, the apex either truncated or obtuse: The apex of the maxillæ somewhat wedge-shaped.

Citreus. *Sp.* 1. *Citreus.* Thorax, at the insertion of the eyes, transversely elevated, the sides anteriorly produced and prominent; eyes equal; abdomen roundish-triagonal, broader behind, with a red line on each side; body yellowish-citron coloured.

Thomise citron, Walck. p. 21. *Thomisus citrinus*, Latr.

Inhabits flowers in Europe. Is common in Britain.

The male is much smaller than the female, of a brown colour, banded with yellowish-green.

Cristatus. *Sp.* 2. *Cristatus.* Lateral eyes placed in a tubercle, the lower ones largest; body pale grey, inclining to reddish; the back of the thorax on each side with a spot, and margins whitish; abdomen somewhat orbiculate, the circumference obscurely brown, with a pale, broad, dorsal band with its side notched.

Thomisus cristatus, Walck. p 32. *Thomisus crist.* Latr.

Inhabits gardens and fields; is very common about Paris. Thoracic spot pale, often bifid in front. Abdomen with five impressed dorsal marks; the anterior one largest, the other four disposed in a quadrangle.

Latreille thinks *Aranea liturata* of Fabricius is near akin to this species.

** Thorax convex heart-shaped, the sides, especially behind, abruptly sloping, the anterior part broadly truncated; the larger feet not twice the length of the body; all of nearly an equal degree of thickness; the hinder four not much shorter; the anterior with four little spines; the nails of all the tarsi scarcely visible. The maxillæ and labium as in the preceding division.

Sp. 3. *Lynceus.* Lateral eyes largest, placed on a tubercle; the tubercles of the hinder ones thickest; body pale yellowish-grey, variegated with punctures and spots of a blackish colour; abdomen very large, of a triangular-oval form, broader behind. Lynceus.

Inhabits France and Scotland.

Thomisus lynceus of Latreille, who considers it much akin to *Thomisus onustus* of Walckenaer, p. 32.

*** Thorax depressed, and somewhat oval, and very obtuse before; the larger feet not twice the length of the body; all of an equal thickness; the tarsi below hairy; the first joint with a few little spines; the apex with two brushes under the nails; abdomen oblong; the maxillæ, beyond the insertion of the palpi, nearly of an equal breadth, distinctly and abruptly truncated; lip somewhat quadrate; hinder lateral eyes distant.

Observation. This divison is near the genus *micrommata* of Latreille's former works.

Sp. 4. *Oblongus.* Pale yellowish, above with white hairs, the abdomen somewhat cylindrical, with the longitudinal obscure lines. Oblongus.

Thomise oblonge, Walck. p. 38. *Thomisus oblongus*, Latr.

Inhabits France and Denmark on plants.

**** Thorax depressed and heart-shaped, truncated before; the four anterior feet more than double the length of the body; the under part of the tarsi in most of the species hairy, in all furnished with two brushes under the nails; the maxillæ short, much inflexed above the lip, nearly of an equal breadth beyond the insertion of the palpi; apex abruptly truncated; lip nearly quadrate, broad; the second pair of feet longest.

A. Eyes arranged in two nearly parallel lines; tarsi hairy beneath; the 3d pair of feet shorter than the 4th.

Sp. 5. *Leucosia.* The four lateral eyes largest; body of a pale dirty yellow, inclining to red; thorax with the anterior margin and a posterior band yellowish-grey; the hinder band margined with black above. Leucosia.

Aranea regia, Fabr. *Thomise leucosie*, Walck. p. 36. *Thomisus leucosia*, Latr.

Inhabits Tranquebar and the Isle of France.

Large; the mandibules obscure red with black ungules; an obsolete blackish spot at the base of the tibiæ; the hairs of the feet spiniform, the hairyness of the tarsi black; the eyes of the anterior line approaching one another in pairs.

Sp. 6. *Lamarckii.* The eyes of the front line largest, and nearly of equal size; body ash-grey; mandibules blackish; breast, middle of the venter, base of the abdomen above, with bands on the feet black. Lamarckii.

Aranea nobilis? Fabr. *Thomisus Lamarck*, Latr.

Inhabits the Isle of France. Was named by La-

Arachnides.

treille, in honour of the celebrated zoologist, Lamarck, who first instituted the ARACHNIDES as a distinct class.

B. Eyes disposed in a semicircle; the under part of the tarsi scarcely hairy; the third pair of feet longer than the fourth.

Venatorius. *Sp.* 7. *Venatorius.* Yellowish-red; abdomen yellow-grey, clouded with ash-grey; feet spotted with black.

Aranea venatoria, Linné. *Aranea pallens?* Fabr. *Thomisus venatorius,* Latr.

Inhabits the American islands.

C. Eyes disposed in a circle; tarsi scarcely hairy beneath; third pair of feet longer than the fourth.

Levipes. *Sp.* 8. *Levipes.* Body grey, spotted with black; abdomen plain, rhomboidal.

Aranea levipes, Linné, Fabr. *Thomise tigré,* Walck. p. 34. *Thomisus tigrinus,* Latr. *T. levipes,* Leach's MSS.

Inhabits the European trees, running swiftly.

48. Oxyopes. GENUS XLVIII. OXYOPES, Latr. SPHASUS, Walck.

Maxillæ straight, longitudinal, and elongate, of an equal breadth nearly from base to apex; apex externally gradually arcuated or bent, internally obliquely truncated. Lip oblong-quadrate.

Feet long and slender, the first pair longest, then the fourth and second, which are nearly equal; tarsi short; nails exserted, no brush beneath.

Variegatus. *Sp.* 1. *Variegatus.* Body hairy and grey, variegated with red and black; feet pale reddish, spotted with brown; the little spines on the tibiæ lengthened.

Sphase hétérophthalme, Walck. p. 19. *Oxyopes variegatus,* Latr.

Inhabits France. The bag containing the eggs round, depressed, and white.

Lineatus. *Sp.* 2. *Lineatus.* Mandibules, thorax, and feet, pale reddish-yellow; mandibules with a line; thorax with three longitudinal fasciæ of a brown colour; abdomen obscurely brown, with longitudinal pale reddish-yellowish lines; the dorsal line branched or forked before.

Oxyopes lineatus, Latreille, (*Genera Crust. et Insect.* vol. i. plate 5, fig. 5.) Inhabits France.

49. Storena. GENUS XLIX. STORENA, Walckenaer's MSS. Latr.

Eyes forming a nearly equal hexagon, disposed in three transverse lines thus, 2, 4, 2.

Maxillæ much longer than the lip, which they cover. Lip oval and lengthened.

Observation. Of the species in this and the following genus we can say nothing, as the genera are unknown to us, and Latreille has not even hinted at the name of a species; notwithstanding this, we conceived the genera ought to be introduced, as it is not improbable that some British species will be found referable to one or other of them.

50. Ctenus. GENUS L. CTENUS, Walckenaer's MSS. Latreille.

Eyes forming an elongate curved angulated line, very open behind, disposed in three transverse lines thus, 2, 4, 2.

Maxillæ longer than the lip. Lip quadrate.

51. Lycosa. GENUS LI. LYCOSA, Latreille, Walckenaer; ARANEA, Linné, Fabricius, Lamarck, Olivier.

Maxillæ straight, anteriorly convex, externally towards the side somewhat arcuated, internally slightly marginated, gradually narrowing towards the base; apex obliquely truncated, almost an inverted triangle.

Lip elongate, quadrate.

Feet strong; the fourth, then the first, after these the second, longest, the third short.

Tarentula. *Sp.* 1. *Tarentula.* Upper part of the body greyish-brown; mandibules and middle of the palpi ferrugineous, the apex of the latter black; thorax with a grey margin, and radiated dorsal line of the same colour; anterior part of the dorsum of the abdomen with triagonal spots, hinder part with bent, transverse, black strigæ, margined with white; belly of a fine crocus yellow, with a transverse black band; thighs and tibiæ below reddish-white, with two black spots.

Aranea tarentula, Linné, Fabr. *Lycose tarentule,* Walck. p. 11. *Lycosa tarentula,* Latr.

Inhabits the South of Europe.

Observations. Lycosa tarentula Narbonensis of Walckenaer, is much smaller than the preceding species; and the belly is black, with a crocus-coloured anus.

Sp. 2. *Ruricola,* greenish-livid-brown, with the margins and abbreviated dorsal line at the base of the abdomen, with the ridge of the thorax and feet pale brown, inclining to livid; the back of the abdomen on each side with a double parallel longitudinal series of fine, small, livid-brown spots. Ruricola.

Lycose agrétique, Walck. *Lycosa ruricola,* Latr.

Inhabits France and Britain, is common early in spring, occurring in marshes and thick woods.

Sp. 3. *Saccata.* Body above, smoke-coloured, inclining to black, clouded with ash-coloured hairs; the ridge of the thorax obscure reddish, with an ash-grey line; the base of the back of the abdomen with a little tuft of hairs; feet livid red, intersected with blackish marks. Saccata.

Aranea Lyonetti, Scopoli. *Lycose à sac,* Walck. *L'araignée Loup,* Geoffroy. *Lycosa Saccata,* Latr.

Inhabits European gardens and cultivated grounds; is very common. The female carries her bag of eggs about with her, the external covering of which is generally a bluish-green, or greenish-blue. The palpi, mandibulæ, and front of the thorax, livid red in the female, black in the male.

Sp. 4. *Velox.* Feet grey-reddish, annulated with black; belly and anus ash-grey; a large red spot at the base of the abdomen, mixed with grey, of a spear shape; middle of the back with a black transverse band, with two spots, and an intermediate splatch of grey. Velox.

Lycosa velox, Walck. *Aranea perita* (*Bullet. de la Soc. Philom. No.* 22.)

GEN. LII. DOLOMEDES, Latreille, Walck.—ARANEA, Linn. De Geer. Fabr. 52. Dolomedes.

Maxillæ straight, oval-quadrate, the apex externally rounded, internally obliquely truncated.

Lip somewhat square, the diameters nearly equal, the points of the angles rounded.

Feet elongate, the fourth longest, then the second, and afterwards the first. The nails of the tarsi exserted, with no brushes below.

Sp. 1. *Mirabilis.* Pale-reddish, covered with greyish down; thorax heart-shaped, anteriorly abruptly sloping; with the anterior angles and dorsal line whitish; abdomen conical, inclining to oval, back darker. Mirabilis.

Aranea saccata? Linné? *Aranea obscura,* Fabr. *Aranea sisteri,* Scopoli. *Dolomède admirable,* Walck. p. 16. *Dolomedes mirabilis,* Latr.

Inhabits Europe, residing in woods. The female is often to be seen carrying about her bag of eggs, the covering or bag being of a greyish dirty yellow colour.

Sp. 2. *Marginatus.* Thorax and upper part of the abdomen obscure brown, the sides margined with white; thorax oval, truncated before; abdomen oval; feet green. Marginatus.

Dolomède bordé, Walck. *Dolomedes marginatus,* Latr.

Inhabits most woods and marshes in France, Germany, Sweden, and England.

II. Feet formed for leaping. Thorax not carinated.

GEN. LIII. ERESUS, Walck. Latr.—ARANEA, Villers. Rossi. Olivier. 53. Eresus.

Maxillæ straight, longitudinal, and somewhat wedge-shaped; the apex broader, rounded externally, internally obliquely truncated.

Arachnides.

Lip nearly an equal sided triangle, the margins somewhat bent back on the point.

Feet strong and short; the fourth, the first, then the second, longest; the third rather shorter than the second pair.

Cinneberinus. *Sp.* 1. *Cinneberinus.* Black; abdomen cinnabar-red above, with four or six black spots, disposed in a double longitudinal line; joints of the feet white; the hinder sides of the thorax, the thighs, with the first joint of the tibiæ of the four posterior feet, pale red.

Aranea moniligera, Villers. *Aranea 4-guttata,* Rossi. *Eresus cinnaberinus,* Latreille, Walckenaer, p. 21.

Inhabits France, Italy, and Germany.

54. Salticus. Gen. LIV. Salticus, Latr.—Aranea, Linn. Fab. Oliv.—Attus, Walck.

Maxillæ straight, longitudinal, and of a somewhat rhomboidal or inverse wedge-shaped oval.

Lip elongate, somewhat oval, apex obtuse.

Feet generally strong, especially the anterior pair, which are short, and formed for leaping; the fourth and first longest, and nearly equal; then the second and third, which are nearly equal in size also.

* Feet thick and short; palpi clubbed; thorax truncate-oval, or parallelogrammic.

Scenicus. *Sp.* 1. *Scenicus.* Black; circumference of the thorax with a white hairy margin; abdomen short, oval, upper part with a greyish-red down, and three transverse undulating bands, and the anus white; the first, or that band nearest the base, unbroken, the others interrupted in the middle.

Aranea scenica, Linné, Fabr. *Salticus Scenicus,* Latr. *Atte Paré,* Walckenaer.

Inhabits walls and palings; is found in most parts of Europe; the female has her palpi white; feet covered with reddish-grey down, and obscure spots. Mandibules of the male very large.

Sanguinolentus. *Sp.* 2. *Sanguinolentus.* Black; the margins of the thorax with a white villose line; abdomen small, somewhat oval, blood-red, with a lanceolate black mark on the middle of the back; the four anterior tibiæ bright yellow.

Aranea sloanii, Scopoli, Rossi. *Aranea sanguinolenta,* Linné, Fabr. *Atte sanguinolente,* Walck. p. 24. *Salticus sloanii,* Latr. *Salticus sanguinolentus,* Leach's MSS.

Inhabits the S. of Europe, seen only once in Britain.

Rumphii. *Sp.* 3. *Rumphii.* Black; variegated with grey and brown; the anterior margin of the thorax with pale reddish down; abdomen elliptical, with an uneven, broad, longitudinal grey band, margined with black.

Aranea rumphii, Scopoli. *Atte tardigrade,* Walck. p. 25. *Salticus rumphii,* Latreille.

Inhabits France, is often taken in the environs of Paris on the trunks of willows.

** Feet long and slender; palpi filiform; thorax long, narrow, and somewhat conic.

Formicarius. *Sp.* 4. *Formicarius.* Thorax black before, red behind; abdomen brown, with a white spot on each side; feet red.

Atte fourmi, Walck. *Salticus formicarius,* Latr.

Inhabits plants and walls throughout Europe, is very rare in Scotland.

Family X. Tarantulides.

55. Tarantula. Genus LV. Tarantula, Brown, Fabricius.—Phalangium, Linné, Pallas.—Phrynus, Olivier, Lamarck, Hermann, Latreille, Herbst.

Palpi long, terminated by a horny, crooked, moveable nail.

Maxillæ obverse-conic, diverging internal angle at the apex lengthened, compressed and rounded.

Body short and depressed; thorax either kidney-shaped or lunulated; no tail.

Eyes eight; two on the middle of the anterior margin, in a transverse line; three on each side, disposed in a triangle.

Lunata. *Sp.* 1. *Lunata.* Palpi nearly three times as long as the body; the apex of the third joint alone spiny; spines four in number, the two upper ones strongest.

Phalangium reniforme, Linné. *Phalangium lunatum,* Pallas. *Tarantula lunata,* Fabr. *Phrynus lunatus,* Latr.

Inhabits the East Indies.

Media. *Sp.* 2. *Media.* Palpi nearly six times as long as the body; the inside spiny from one end to the other; the spines at the point very numerous.

Phrynus medius. Herbst. Inhabits South America?

Reniformis. *Sp.* 3. *Reniformis.* Palpi length of the body, the second and third joints compressed, and spiny on the inside; the last joint internally dilated, and armed with five or six strong spines.

Phalangium reniformis, Pallas. *Cancellus aranoides,* Petiver. *Tarantula reniformis,* Fabr. *Phrynus reniformis,* Latreille.

Inhabits South America; is common in Jamaica, St Domingo, and other islands.

56. Thelyphronus. Genus LVI. Thelyphronus, Latreille. Phalangium, Linn. Pall. Tarantula, Fabricius.

Palpi short and thick, terminated by a forceps, or finger and thumb.

Maxillæ nearly triangular, and large, meeting within.

Body elongate, and cylindrical; thorax oval; abdomen terminated by a tail.

Eyes as in the preceding genus.

Proscorpio. *Sp.* 1. *Proscorpio.* Palpi spinous or branched.

Phalangium caudatum, Linné, Pallas? *Tarantula caudata,* Fabricius? *Thelyphronus proscorpio,* Latr.

Family II. Scorpionides.

57. Scorpio. Genus LVII. Scorpio, Linn. Fabr. Oliv. Latr. Lam. Herbst, Shaw, Donovan.

Maxillæ short, rounded, internally somewhat arched and hairy.

Lip with four triangular porrect pieces or valves, the two external ones joined to the anterior, the two internal ones to the base of the second pair of feet.

Eyes six or eight.

Body elongate; with two pectinated laminæ (which are denominated pecten) at the under base of the abdomen.

Tail composed of six joints, the last sharp or aculeated; the sting bent, instilling poison into the wound it makes.

* Eyes eight in number.

Occitanus. *Sp.* 1. *Occitanus.* Pectens with twenty-eight teeth; body yellowish; tail longer than the body, with elevated granulated lines, with no prominence under the sting.

Scorpio occitanus, Amoreux, (*Jour. de Phys.* 1789.) Latr. *Scorpio tanetanus,* Redi.

Inhabits the southern parts of Europe.

Afer. *Sp.* 2. *Afer.* Pectens with thirteen teeth; hands somewhat heart-shaped, hairy, and slightly granulated.

Scorpio afer, Linn. Fabricius.

Inhabits India.

Americanus. *Sp.* 3. *Americanus.* Pectens with fourteen teeth; hands somewhat ciliated; fingers filiform.

Scorpio Americanus. Linné, Fabricius.

Inhabits America.

Australis. *Sp.* 4. *Australis.* Pectens with thirty-two teeth; hands smooth, elongated and red; the fingers filiform; under the sting a pointed process.

Scorpio Australis. Linné, Fabricius.

Inhabits Africa.

Carpathicus. *Sp.* 5. *Carpathicus.* Pectens with eighteen teeth; hands angular; tail mucronated beneath the sting.

Scorpio Europæus, Linné, Fabr. *Scorpio Carpathicus,* Latr. *Scorpio Germanicus,* Herbst.

Arachnides.

The habitat is not known to us; but Latreille says it is an extra-European species.

** Eyes six in number.

Europæus. *Sp.* 6. *Europæus.* Pectens with nine teeth; hands somewhat heart-shaped, angular; the wrists with one tooth; body obscure brown; last joint of the tail, with the feet brownish-yellow.

Scorpio Europæus, Villers, Latreille.

Inhabits the south of Europe.

Linné was not acquainted with this species; he has described some other for it, and has led the celebrated Fabricius into a similar error respecting it: See the note following *Scorpio carpathicus, Sp.* 5. where we have corrected this mistake. De Geer has described a Cayenne species for *Europæus,* 7. 344. tab. 41. Fig. 5.

Maurus. *Sp.* 7. *Maurus.* Pectens with eight or ten teeth; hands cordate, nearly smooth; body fuscous, and granulated.

Scorpio maurus. Linné, Fabricius, and Latreille.

Inhabits Barbary.

58. Chelifer. Genus LVIII. Chelifer. Geoff. De Geer, Oliv. Lam. Herm. Latreille.

Phalangium, Linn. Scorpio, Fabricius. Obisium, Illiger, Walckenaer.

Maxillæ longitudinal, large and convex, on the inner side inflexed, and meeting together; the apex produced into a point. *Lip* none.

Eyes two or four inserted into the sides of the thorax.

Body somewhat depressed. *Tail* none.

* Eyes two. Thorax divided into two parts by a transverse line.

Cancroides. *Sp.* 1. *Cancroides.* Arms twice the length of the body, the second and third joints elongate and conic; body red-brown; abdomen oval.

Chelifer cancroides, Latreille.

Inhabits close places, and books, living on *Acaridiæ;* when touched, it walks backwards, holding forwards its hands in a menacing attitude.

Cimicoides. *Sp.* 2. *Cimicoides.* Arms of a moderate length, the joints somewhat oval and hairy; abdomen globose-oval.

Scorpio cimicoides, Fabr. *Pince parisite,* Hermann. *Obise cimicoide,* Walck. *Chelifer cimicoides,* Latr.

Inhabits Europe, under the bark of trees.

** Eyes four; thorax entire.

Trombidioidos. *Sp.* 3. *Trombidioidos;* mandibulæ very large and exserted; the second joint of the arms elongate; fingers long and straight.

Pince trombidioides, Latr. *Pince ischnochéle,* Hermann. *Chelifer trombidioides,* Latr. *Obisium trombidioides,* Leach's MSS.

Inhabits France; is common near Paris, under stones, and in other parts of France among mosses. In this country it has been discovered by Montagu and Leach, in Devonshire, under stones, in tolerable plenty; and by the latter gentleman in Surrey, near Godstone.

Obs. These two divisions of the genus certainly have distinct characters enough to form two genera; we therefore, perhaps, should follow Mr Leach, who proposes to call the first division Chelifer, a name first given by Geoffroy; the second Obisium, a name proposed by Illiger for the genus as it now stands.

59. Cellularia. Genus LIX. Cellularia. *Vide* synopsis of genera.

Method of Preserving the Animals of this Class.

Those of the first order may be simply dried, having a pin passed through the right side of their body; the legs being spread as if the animal were walking. The smaller species of the Second Order are to be glued to paper, by means of gum arabic; and the larger ones must either be kept in spirit, or dried very rapidly in a strong blast, in a dark place if possible.

APPENDIX.

Appendix. In this part of the article, we shall add those species which have been discovered since the former part was written, and some alterations in the classification, lately made by Dr Leach.

He has divided the tribe Millepeda from the Crustacea, and considered them as a distinct class, under the title of Myriapoda, and has placed the Oniscides and Asellides with the Gasteruri.

The characters of Crustacea, Myriapoda, Arachnides, and Insecta, are given in the following Table.

Animals without a Vertebral Column, with distinct Nerves and Feet.

- With gills or branchiæ. . . . . Class Crustacea.
- With air tubes or tracheæ.
  - With a heart.
    - With antennæ and distinct head. Class Myriapoda.
    - Without antennæ, head united to the thorax. Class Arachnides.
  - Without a heart. Class Insecta.

The genus Bopyrus is to be altogether rejected from this article, as it belongs to the class Vermes.

Class CRUSTACEA.

The two orders, I. Entomostraca, and, II. Malacostraca, he considers as sub-classes, but suffers them to retain the same names. In the Entomostraca, nothing new has occurred; but to the Malacostraca, we can add much valuable matter.

Subclass II. MALACOSTRACA.

This subclass is subdivided into three orders: 1. *Brachyuri, Macrouri,* and *Gasteruri,* which are synonymous with the tribes of those names before given.

Order I. Brachyuri.

The first division containing those genera with the hinder tarsus and unguis formed for swimming, is now (as we have before hinted) divided into more genera, the characters of which may be given in a table.

* The peduncle of the eyes as long as the external angles of the shell.

Genus I. Podopthalmus.

** Peduncle of the eyes much shorter than the external angles of the shell.

A. Shell with more than five teeth on each side.

Genus II. Lima. Shell remarkably transverse; at the termination of the semicircle on each side armed with a long spine.

B. Shell with five teeth on each side.

Genus III. Portunus. Transverse diameter of the shell much greater than the longitudinal; orbit of the eye behind, with two fissures. Eyes thicker than their peduncles.

Genus IV. Carcinus. Transverse diameter of the shell much greater than the longitudinal; orbit of the eye behind with one fissure; eyes not thicker than their peduncles.

Genus V. Portumnus. Longitudinal diameter of the shell equal, or nearly equal, to the transverse; or-

Appendix.

bit of the eye without any fissure behind; eyes not thicker than their peduncles.

The species of these genera have already been given in the early part of this article, under the generic title of PORTUNUS.

The genus CANCER, too, admits of several very important divisions, but three genera only have hitherto been formed, viz. CANCER, XANTHO, and ATELECYCLUS.

GENUS I. CANCER. Shell broad, the anterior margin gradually bent into a semi-elliptic form, the ends gradually converging into an angle behind, the apex truncate and marginate: the external antennæ setaceous and short, the two first joints largest; inserted betwixt the front and internal canthus of the eye: Peduncle of the internal antennæ somewhat lunate. Second joint of external double palpi, with the internal apex emarginate or notched for the insertion of the palpi: Feet simple, compressed, the hinder ones shortest. Nails somewhat compressed and hairy, the sides with an excavated line, joints naked and somewhat acute.

Sp. 1. *Pagurus*. See p. 391 of this article.

GENUS II. XANTHO. Shell as in Cancer, but the hinder edge is only submarginate. External antennæ very short, setaceous, the two first joints largest, inserted at the internal corner of the eye; peduncle of the internal antennæ somewhat linear. Palpi as in Cancer. Feet simple, compressed, hinder ones shortest. Nails compressed, hairy, the sides with an obscure impressed line, points naked, and scarcely acute.

Sp. 1. *Incisa*. Wrists with two tubercles above; shell on each side with four obtuse teeth, the interstices notched; fingers generally black, in some individuals same colour with the shell, which is most frequently reddish, or brownish-red.

Cancer incisus of this article. See p. 391.

Obs. 1. *Cancer dodone* of Herbst seems to be referable to this genus, as far as we can judge from his plate: it differs in having only three obtuse teeth on each side of the shell.

Obs. 2. *Cancer denticulatus*, *Hirtellus* and *Spinifrons*, seem also to form distinct genera, but the characters have not yet been developed.

GENUS III. ATELECYCLUS. The characters have not yet been completely developed; it is readily distinguished from any other genus by the form of its shell, which is almost continued from the front to the hinder edge into a circle, which is however interrupted in that part, forming altogether an imperfect or interrupted circle. The antennæ, too, are as long as the shell.

Sp. 1. *Septemdentatus*. With seven distinct teeth on the sides of the shell, and some intermediate small ones.

Cancer hippa septemdentatus, Montagu.

First discovered by Montagu on the S. coast of Devon, and described by him in the 11th vol. of the *Lin. Trans.* It has since been found by Mr Cranch of Kingsbridge to be very common in the Plymouth Sound. Dr Leach received the young of the female from the Bell Rock, sent him by Mr Stevenson. The full grown female has never yet occurred.

Cancer undecemdentatus of Herbst, tab. 10. fig. 60. seems to belong to this genus. It inhabits America.

The genus OCYPODE Dr Leach has also found it necessary to divide into the following genera.

* Shell rhomboidal, inclining to square; peduncle of the eyes reaching the anterior external angles of the shell.

GENUS I. OCYPODE. Peduncle extending beyond the eyes; anterior feet very unequal.

GENUS II. UCA. Peduncle not extending beyond the eyes; the anterior feet very unequal.

GENUS III. GONEPLAX. Peduncle not extending beyond the eyes; anterior feet equal.

** Shell truncate-heart-shaped; peduncle of the eyes much shorter than the anterior external angles of the shell.

GENUS IV. GECARCINUS.

To the genus OCYPODE, *O. ceratopthalmus* of this article are referable. To UCA, *Cancer uca* of Shaw's *Nat. Miscellany*, plate 588, belongs; the species to be named *Una*. To GONEPLAX, *O. Angulata* of this article, which should be named *G. bispinosa*, is the prototype. To GECARCINUS, *O. ruricola* and *cordata* of this article are the only species we know to belong to it.

GEN. GRAPSUS. To this genus *Cancer minutus* of Linné is referable.

GEN. PINNOTHERES.

Sp. 1. *Pisum*. (Female.) Shell orbicular, soft, very smooth, with the front somewhat arcuate and entire; hands oblong, the under part a line of ciliæ, as are the upper parts of the thighs of the other legs; thumb somewhat arcuate; abdomen very broad, the sides of the segments arcuate, the fifth segment broader; the last segment narrower than the preceding; the apex broadly notched.

Cancer pisum, Pennant, Fabricius, Linné.

Pinnotheres pisum, Latreille, Leach, *Mem. Wern. Soc.* vol. ii. *Mal. Brit.* PINNOTHERES, tab. A.

Inhabits the shells of mussels and oysters; male unknown.

Sp. 2. *Mytili*. (Female.) Shell orbicular, inclining to quadrate, soft, very smooth, the sides behind dilated; front strait, obscurely, somewhat notched; hands oblong; under parts, with the upper part of the thighs of the other legs, having a ciliated line; thumb somewhat arcuate; abdomen very broad, the segments at their sides somewhat arcuate; hinder edge of the third and following joints notched in the middle; fifth segment broader, the last narrower than the preceding.

P. Mytili. Leach, *Mem. Wern. Soc.* vol. ii. Malacostraca Britannica. PINNOTHERES, tab. A. Male unknown.

This interesting species was discovered by a most zealous and enlightened collector, Mr Cranch, in *Mytilus modiolus*, from the Kingsbridge estuary, dredged from the oyster bed near Gerston Point.

Sp. 3. *Mytilorum*. (Female.) Shell ovate-orbicular, anteriorly somewhat narrower, convex very smooth, somewhat solid; front produced entire, scarcely somewhat arcuate; sides in each side behind, with two oblique impressed lines running together behind; hands somewhat oval, beneath, with the upper part of the thighs with a ciliated line; fingers arcuate; abdomen somewhat narrow, the segments with their sides somewhat arcuate, the last narrower than the preceding, the apex somewhat acuminate, rounded at the extreme point, and entire.

Cancer mytilorum albus of Herbst.

Pinnotheres mytilorum of Latreille. Leach, *Mem. Wern. Soc.* vol. ii. Mal. Brit. PINNOTHERES, tab. A.

A single specimen of this species was taken by Dr Leach from *Mytilus modiolus*, dredged at Newhaven in the Frith of Forth, who, for a long time, considered it as the young of *P. Pisum*. Male unknown.

Sp. 4. *Varians*. (Male.) Shell ovate-orbicular, anteriorly somewhat narrower, convex very smooth, and solid; front produced, arcuate, and entire; hands ovate, beneath with two lines of ciliæ; fingers much arcuated; thighs above and below with a line of ciliæ; and sides of the abdomen broadly notched, the last joint abruptly narrower than the preceding, the apex narrower, rounded, and entire.

Cancer varians, Oliv. Enc. Meth. H. Nat. tab. vi. p. 155.
Cancer mytilorum fuscus, Herbst.

Inhabits *Mytilus modiolus*. Is common in the Frith of Forth, and was considered as the male of *Pisum* by Dr Leach, until the distinctions of the ciliated lines were pointed out to him by that acute and learned zoologist Montagu.

Sp. 5. *Pinnæ*. Front somewhat emarginate; hands beneath, with an arcuate emargination.

Male, with the shell transversely, somewhat quadrate, somewhat solid and punctate; hands ovate, fingers arcuate; sides of the abdomen entire, the last joint abruptly broader than the preceding, the apex acutely somewhat rounded.

Female, shell somewhat transversely, somewhat quadrate, soft, and very minutely punctate; hands elongate-ovate, with the fingers somewhat arcuate; abdomen very broad, with a kind of carina of knots, the fifth, sixth, and seventh segments emarginate behind, the last joint narrower than the preceding.

Cancer Pinnotheres, Linné?

Pinnotheres pinnæ, Leach, *Mem. Wern. Soc.* vol. ii. Malacos. Britan. PINNOTHERES, tab. B.

Mus. Montagu, male and female. *Mus.* Leach, female.

Discovered by Montagu in *Pinna ingens*, from the Salcombe estuary; since which, Mr Cranch has taken two females out of the same shell from the same situation.

Sp. 6. *Modioli*. (Male.) Shell transversely, somewhat quadrate, somewhat solid, and punctate; front emarginate; hands ovate, fingers arcuate; sides of the abdomen widely notched, the last joint somewhat abruptly broader than the preceding, the apex obtusely rounded and entire.

Pinnotheres modioli, Leach, *Mem. Wern. Soc.* vol. ii. Malacost. Brit. PINNOTHERES, tab. B.

Discovered by Montagu in *Mytilus modiolus*, from the Kingsbridge estuary. Female unknown.

The paper by Leach here quoted as in "Mem. Wern. Soc. II" is not in that publication.

The reference to "Malacos. Brit" is obviously to proof plates. That work began in 1815 & the plates have numbers. In the text of that work this article is cited, but no reference made to "Mem. Wern. Soc.

paper to which we have alluded, has been ...

* Abdomen with seven joints.

The genera in this division have been examined but not defined; we shall, however, give the name of the genera, with one species of each genus.

GENUS I. PARTHENOPE, Fabricius.

Sp. 1. *Maia Horrida* of this article, see page 394.

GENUS II. MAIA.

Sp. 1. *Squinado* of this article, see p. 394. This species is improperly mentioned as the *Dodecos* of Linné by Montagu, in the seventh volume of the *Linnean Transactions*, when he describes his *Cancer maxillaris*.

GENUS III. HYAS.

Sp. 1. *Araneus*. *Maia Araneus* of this article, see p. 394.

GENUS IV. EURYNOME.

Sp. 1. *Aspera*. *Cancer asper* of Pennant. As full grown specimens have not yet occurred, we cannot give the specific characters.

GENUS V. BLASTUS.

Sp. 1. *Tetraodon*. *Cancer tetraodon* of Pennant; and also probably *Maia armata* of Latreille.

GENUS VI. PISA.

Sp. 1. *Biaculeata*. *Cancer biaculeatus*, Montagu, *Lin. Trans.* vol. ix.

** Abdomen with six joints.

GENUS I. INACHUS. Exterior antennæ, with the three first joints largest; eyes distant; feet very long and slender, the anterior pair excluding the arms, thicker than the three hinder pair; shell somewhat triangular, scantily spined, and rostrated in front, with a projecting spine on each side over the eyes, which protects them as it were in a spurious orbit.

Sp. 1. *Dorsettensis*. Rostrum short and tricuspid, with equal teeth, middle one acute placed beneath; shell behind the rostrum, with four small equal tubercles disposed in a strait transverse line; behind these three spines, the middle one placed rather more anteriorly; behind these again, three others stronger and more acute, placed in a recurved line; the hinder margin, with two distant obsolete tubercles.

Cancer dorsettensis of Pennant. *Cancer Scorpio*. Fabr. *Ent. Syst.* *Inachus Scorpio*. Fabr. *Sup. Ent. Syst.*

Inhabits the western coasts of England. Is common at the mouths of rivers, and in deep water far from land.

Sp. 2. *Dorynchus*. Rostrum somewhat lanceolated, with a fissure running down the middle; shell behind the rostrum, with three spines placed in a triangle, the hinder one largest; behind these are two tubercles, one on each side, then four other tubercles, one on each side, and two in the middle near to one another, placed somewhat behind the lateral ones; posterior margin with two distant obsolete tubercles.

This was discovered by Dr Leach, whilst he was washing some specimens of I. *Dorsettensis*, sent him by Mr Prideaux and Mr Cranch from the Kingsbridge estuary.

Leach, *Malacos. Brit. Inachus*,

...IA. Exterior antennæ, with the ... eyes distant; first pair of legs ...ollowing legs; shell somewhat ...l, anteriorly rostrated; no spine

...*aia phalangium*, see p. 395, which ...th *Cancer rostratus* of Herbst. This differs from *Phalangium*, ... longer and narrower, and the

...th Sound. First noticed as dis-

I. MACROURI.

GENUS PENÆUS. See page 401. To the generic character add *pediform palpi*, with five exserted joints, last joint obtuse and simple.

GENUS ALPHÆUS. See page 400. To this genus, *Cancer spinus* of Sowerby, described in the *British Miscellany*, is referable. The *pediform palpi* with three exserted joints, the last joint furnished with spines.

Sp. 2. *Trisulcatus*. Back of the thorax with three grooves; rostrum turning downwards, with two teeth beneath and many above.

Penæus trisulcatus, Leach, *Malacos. Brit.* PENÆUS, tab. A.

Mus. Sowerby.

Discovered in Anglesea by the Rev. H. Davies, who sent it to Mr Sowerby.

GEN. HIPPOLYTE. Superior antennæ with two setæ, the lower seta largest, the upper compressed; pediform

Appendix. palpi, with three exserted joints, the last spiniferous; four anterior feet, didactyle, the anterior pair shortest and thickest; nails of other feet spinous; third joint of abdomen gibbous above.

Observe. To this genus *Cancer astacus gibbosus* of Montagu, already referred to in the note after *Penæus*, page 401, belongs.

Sp. 1. *Varians.* Rostrum strait, with two teeth above and beneath; shell above and beneath the eyes with a spine.

Inhabits the rocky shores of Devon in great plenty.

Hippolyte varians; Leach, *Mem. Wern. Soc.* vol. ii.

There are other species which are not well understood.

Gen. Pandalus. Superior antennæ with two setæ, the inferior ones with a squama at their base. First pair of feet simple, the second pair didactyle; nails of the other feet spinulose; third segment of the abdomen gibbous above; pediform palpi, with three exserted joints, the last acuminate and spinigerous.

Sp. 1. *Montagui.* Rostrum turning upwards, with many teeth above, and the apex emarginate, with six teeth beneath; antennæ ringed with white and red alternately.

Pandalus Montagui, Leach, *Malacos. Brit. Pandalus,* Tab. A. named in honour of the first discoverer, Montagu, by whom it was called *Astacus maculatus.* The Rev. J. Fleming took this species in Zetland, whose successful labours, in that country speak more than we can do in words.

Gen. Palæmon. Page 401. A. Anterior pair of feet smaller than the second; pediform palpi, with the last simple and acuminate, shorter than the preceding joint; superior antennæ with three setæ.

Observe. We can correct an error in nomenclature, which we have lately discovered.

Sp. 1. *Serratus.* Rostrum ascending, above with from six to eight teeth, and the apex notched; beneath with from four to six teeth.

Astacus serratus of Pennant. *Palæmon squilla* of Latreille; and this article, page 401. *Palæmon serratus* of Fabricius, seems referable to a distinct genus, from his description, if it be correct.

Sp. 2. *Squilla.* Rostrum strait, with from seven to eight teeth above, and two to three beneath.

Cancer squilla, of Linné.

Is very common on the Devonshire coast; has the same colour as *P. serratus,* but spawns at a different season. A little shorter than the preceding species.

Sp. 3. *Varians.* The rostrum strait, with from four to six teeth above and three beneath.

Is common at Yarmouth, and is frequently also taken on the Devon and Glamorgan coasts.

Gen. Athanas. *Palæmon.* Page 401. B. Anterior larger than the second pair of feet; pediform palpi, with joint simple and acuminate longer than the preceding; superior antennæ with three setæ.

Sp. 1. *Nitescens.* *Palæmon nitescens.* Page 401.

ORDER III. GASTERURI.

Tribe I. GNATHIDES.

This includes our former family, *Gnathonii.*

Tribe II. GAMMERIDES.

This tribe includes our family *Gammarini,* which is now divided into several families. The last character, viz. "tail not distinct from the body," should be cancelled.

Family I. Orchestidæ.

Antennæ four jointed, the last joint composed several minute joints; the upper ones very short, shorter than the peduncle of the under ones.

Genus I. Talitrus. Page 402. Appendix.

Sp. 1. *Locusta.* Dr Leach has discovered *T. littoralis* to be merely the other sex of this species.

Genus II. Orchestia. Page 402. Four anterior feet of the male monodactyle, the second pair largest; of the female equal in size, the first pair monodactyle, the second didactyle.

Family II. Dexameridæ.

Antennæ three-jointed, the last joint composed of several other minute articulations; upper ones longest.

* *Two anterior pair of feet monodactyle.*

Genus III. Dexamine. Four anterior feet nearly equal; hands subovate, compressed, and filiform.

Sp. 1. *Spinosa. Cancer gammarus spinosus* of Montagu.

** *Anterior pair of feet didactyle; second pair monodactyle.*

Genus IV. Leucothöe. Thumb of anterior feet with two joints; second pair with a compressed hand, furnished with a curved thumb.

Sp. 1. *Articulosa.* Page 403.

Family III. Gammaridæ.

Last joint of the antennæ composed of several minute articulations; upper pair longest, four jointed; under ones five-jointed.

* *Second pair of feet larger than the first, with a compressed hand.*

Genus V. Melita. Second pair of feet (in the male at least) with the thumb bending upon the palm; last joint of the antennæ entire.

Sp. 1. *Melita palmeta.* Page 403.

Genus VI. Mæra. Second pair of feet with a large compressed hand and single thumb; last joint of the antennæ bifid.

Sp. 1. *Grossimana.* Page 403.

** *Four anterior feet nearly equal in size and form, with ovate hands.*

Genus VII. Gammarus. Last joint but one of the superior antennæ with a litle seta at the apex at the base of the articulated last joint; back of the tail with ciliæ of spines.

Contains *Gammarus pulex, locusta,* and *camylosps* of this article, page 402 and 403.

Genus VIII. Ampithöe. Superior antennæ, without a seta at the base of the last joint; back of the tail without fasciculi of spinules.

Sp. 1. *Rubricata. Gammarus rubricatus.* Page 403.

*** Four anterior feet with a filiform hand.

Genus IX. Pherusa.

Sp. 1. *Fucicola.* Colour whitish, nuttled with reddish.

Found on the rocky shores of Devon, under stones at low tide, on fuci.

Family IV. Podoceridæ.

Superior antennæ shortest four-jointed, the last joint solid or obscurely articulated; inferior antennæ five-jointed, with the last joint solid, or very obscurely articulated.

* *Superior antennæ very short, the last joint composed of many minute articulations.*

Genus X. Corophrium. Body elongate, ten-jointed; tail three-jointed, the first joint and the second with a bifid style; the last with two moveable papillæ; anterior pair of feet small, with the apex somewhat truncate, and furnished with a little thumb; second pair larger, armed with a thin curved thumb.

Dr Leach formerly considered this genus as constituting a peculiar family, which, with the addition of two other genera, he has now completely established as such. For the species, see page 403.

Appendix.

** Superior antennæ shorter than the under ones; the last joint scarcely articulated.

Genus XI. Podocerus. Eyes hemispherical and somewhat prominent; four anterior feet didactyle, anterior pair smallest with an elongate-subovate hand; second pair with an ovate hand, and the internal side nearly strait.

Sp. 1. *Variegatus.* Body, legs, and antennæ beautifully variegated with red.

Podocerus variegatus. Leach's MSS.

Inhabits the rocky shores of Devon, walking about on fuci and corallines with its antennæ as well as legs.

Genus XII. Jassa. Eyes not prominent; four anterior feet didactyle with ovate hands; the anterior pair smallest; the hand of the second pair with the internal edge furnished with teeth.

Sp. 1. *Pulchella.* Thumb of the second pair with the internal edge emarginate at the base.

Var. α. Internal edge of the hand of the second pair of feet with an elongated tooth at the base.

Var. β. Internal edge of the second hand with three teeth.

Iassa pulchella. Leach, *Mem. Wern. Soc.* vol. ii.

Inhabits fibrous fuci on the Devonshire coast every where. White painted with red.

Sp. 2. *Pelagica.* Hand of the second pair with the internal edge having a lunar notch.

Iassa pelagica. Leach, *Mem. Wern. Soc.* vol. ii.

Received through Mr Stevenson's kindness from the Bell Rock, in the German Sea.

Cancer gammarus falcatus of Montagu. *Lin. Trans.* vol. ix. tab. 5. fig. 2. seems referable to this genus.

Tribe III. PHRONIMARIDES.

Extremity of the tail furnished with several styles; feet ten.

This tribe contains the genus Phronima, mentioned in p. 403, which might constitute a distinct family.

Tribe IV. CAPRELLIDES.

This includes our family Caprellini, to which we can add another genus, differing from *Caprella* in having true legs instead of the gelatinous fine-like legs, which is naved.

Gen. Proto.

Sp. 1. *Pedata.*

Cancer gammarus pedatus. Montagu, *Linn. Trans.* vol. xi. p. 6. tab. ii. fig. 6.

Tribe V. APSEUDIDES.

Comprehending our family Apseudii, p. 404.

Tribe VI. ASELLIDES.

Antennæ four, distinct; last segment of the tail long.

Family I. Anthuridæ.

Last segment of the tail very short, the last narrow, elongate, with two elongate lamellæ on each side; antennæ nearly equal, inserted one behind the other in nearly an horizontal line.

Genus II. Anthura. See Genus LXV.

Family II. Cymothoidæ.

Last segment of the tail with one or two appendages on each side; antennæ placed in pairs, one above the other.

Stirps 1. Last segment of the tail on each side with a single appendage.

Genus III. Campecopea. See Genus LXIX.

Genus IV. Nesæa. See Genus LXVIII.

Stirps 2. Last segment of the tail with two appendages on each side.

* Upper antennæ with a very large peduncle; head behind bilobate, the eyes placed on the lobes.

Genus V. Cymodoce. Eyes touching the anterior margin of the first segment; base of the tail on each side with two equal slightly compressed (but not foliaceous) appendages, exterior ones largest; last segment emarginate, with a lamella in the middle; nails bifid.

Sp. 1. *Truncata.* Apex of tail truncate.

Inhabits the coast of Devon amongst fuci, but is very rare. Leach's MSS.

Oniscus truncatus, Montagu's MSS.

Genus VI. Dynamene. Eyes not reaching the anterior margin of the first segment; base of the tail on each side with two equal foliaceous appendages, apex of the tail emarginate; nails bifid.

There are several indigenous species of this genus, but the characters are not yet determined.

Genus VII. Sphæroma. Eyes not reaching the anterior margin of the first segment; last joint of the tail entire, the base on each side furnished with two equal foliaceous appendages; nails bifid.

Sp. 1. *Serrata.* Add to the character given in p. 405. "External foliaceous appendage of the tail externally serrated."

Sp. 2. *Rugicauda.* Add, "foliaceous lamellæ not serrate externally."

Sp. 3. *Hookeri.* Last joint of the tail with two oblong obsolete tubercles.

Spheroma Hookeri. Leach, *Mem. Wern. Soc.* vol. ii.

Discovered by Mr W. J. Hooker on the Norfolk coast.

** Peduncle of upper antennæ not very large.

Genus VIII. Cymothoa. Head narrower than the first segment of the body, and received into a notch in that part; eyes obscure; tail narrower than the body, the last segment of the tail transversely quadrate, with two styles on each side at the base.

Sp. 1. *Œstrum,* page 405.

Genus IX. Limnoria. Head as broad as the first segment of the body; eyes granulated and distinct; tail scarcely narrower than the body; last segment of the tail rounded at the apex; the base in each side with two styles.

Sp. 1. *Terebrans.* Body cinereous; eyes somewhat pitchy-black.

Limnoria terebrans. Leach, *Mem. Wern. Soc.* vol. ii.

Length from one line to two.

This new and highly interesting species was sent to Dr Leach by Mr Stevenson, from the Bell Rock, in logs of wood, which it perforated in the most alarming manner. He has since received it from the coast of Suffolk. It generally produces seven young ones.

Family III. Asellidæ.

Last segment of the tail very large; middle antennæ very short; external antennæ half the length of the body, or more.

Stirps 1. Tail with two styles at the apex; antennæ filiform.

Genus X. Idotea. External antennæ half the length of the body, or scarcely longer, the third and fourth joints equal; body ovate.

Sp. 1. *Entomon,* see p. 404.

Sp. 2. *Œstrum,* see p. 404.

Genus XI. Stenosoma. External antennæ longer than the body, the third longer than the fourth joint; body linear.

Sp. 1. *Hectica.* Apex of the tail truncate.

Idotea hectica of this article. See page 404.

Sp. 2. *Acuminata.* Apex of the tail acuminate.

Stenosoma acuminata. Leach, *Mem. Wern. Soc.* vol. ii.

Taken on the Devonshire coast by Dr Leach.

Stirps 2. Apex of the tail with two bifid styles; antennæ setaceous.

* *Styles very minute, scarcely exserted; anterior feet like the others; without a head.*

Genus XII. Jæra. Eyes of the middle size inserted betwixt the sides of the head and the vertex.

Sp. 1. *Albifrons.* Head anteriorly whitish.

Oniscus albifrons, Montagu's MSS.

Jæra albifrons. Leach, *Mem. Wern. Soc.* vol. ii.

Inhabits the British sea every where, under stones and amongst fuci.

** Styles of the tail exserted; anterior feet larger than the others, with a moveable thumb.

Genus XIII. Janira. Nails bifid; eyes of a moderate size, inserted on the sides of the head towards the vertex.

Sp. 1. *Maculosa.* Light cinereous, mottled with brownish speckles.

Oniscus maculosa, Montagu's MSS.

Janira maculosa. Leach, *Mem. Wern. Soc.* vol. ii.

Inhabits the Devonshire coasts, under stones, but is rare.

Genus XIV. Asellus. Nails simple; eyes minute and lateral.

Sp. 1. *Aquaticus,* see p. 404.

Tribe VIII. ONISCIDES.

Internal antennæ very minute, scarcely discernible.

Family I. Ligidæ.

Caudal styles two on each side, sitting on a common peduncle in hairs.

Genus XV. Ligia, see Genus LXXI.

Sp. 1. *Oceanicus.* *Ligia scopulorum* is merely a variety of this species, see p. 406, as we have found every intermediate variety in size and sculpture.

Family II. Oniscidæ.

Caudal styles two on each side, the lateral one two-jointed.

Stirps 1. Body not contractile into a globe.

* External antennæ with eight joints.

Genus XVI. Philoscia, see Genus LXXII.

Genus XVII. Oniscus, see Genus LXXIII.

** External antennæ with seven joints.

Genus XVIII. Porcellio, see Genus LXXIV.

Stirps 2. Body contractile into a globe.

Genus XIX. Armadillo, see Genus LXXV.

This genus intimately connects the Orders Tetracera with the Duocera.

Class MYRIAPODA.

Order I. CHILOGNATHA.

Includes Fam. 20. Julides of this article. p. 387 and 407.

Family I. Glomeridæ.

Body contractable into a ball.

Genus XX. Glomeris. Feet on each side sixteen. See p. 407.

Genus XXI. Cryxus. Feet on each side twenty. See p. 407.

Family II. Julidæ.

Body not contractable into a ball.

Stirps 1. Antennæ inserted on the superior margin of the head.

* *Eyes distinct and granulated.*

Genus XXII. Julus. See Gen. p. 407.

Genus XXIII. Craspedosoma. See Gen. Julus ** p. 407.

** *Eyes obsolete.*

Genus XXIV. Polydesmus. See Gen. LXXVIII.

Stirps 2. Antennæ inserted under the anterior margin of the head.

Genus XXV. Polyxenus. See Gen. LXXIX.

Order II. SYNGNATHA.

Family I. Scutigeridæ.

Segments of the body bearing four feet.

Genus XXVI. Scutigera. See Gen. LXXX.

Family II. Scolopendridæ.

Segments of the body with a single pair of feet.

Stirps 1. Last pair of feet remarkably larger than the rest.

* Feet thirty.

Genus XXVII. Lithobius. See Gen. LXXXIII.

** Feet forty.

Genus XXVIII. Scolopendra. See Gen. LXXXI.

Genus XXIX. Cryptops. See Gen. LXXXII.

Stirps 2. Last pair of feet not very much larger than the rest.

Genus XXX. Geophilus. See Gen. LXXXIV.

Class ARACHNIDES.

Those of this class having but six feet, may be arranged in a more perfect manner: we can add one new genus, and the genus *Nycteribia* of Latreille is also referable to this division, although he has placed it with the insects.

Hexapoda.*

Tribe I. Cephalostoma.

Mouth situated in the head.

Family I. Phænorhynchi.

Mouth porrected and easily to be seen.

Genus I. Caris. See Gen. IV.

Genus II. Leptus. See Gen. V.

Genus III. Ocypete. Mouth rostriform, porrected betwixt the palpi.

Palpi elongate-conic, incurved, the last joint acute, corneous, and nail-like, abruptly narrower than the preceding, underneath at the base with a conic (soft?) elongate moveable appendage. Body soft, oval, smooth, the upper part anteriorly, as if divided into two parts by a transverse line; the anterior division a little narrower, and bearing the mouth, eyes, and four anterior feet. Two eyes on each side close to one another, prominent, (or placed on a peduncle?), inserted above the base of the anterior feet. Feet six-jointed, the last joint of the anterior pair thickest.

Between the eyes, which are inserted longitudinally, there is a black spot above the base of the rostrum.

This genus seems akin to the *Trombidia* in the parts of the mouth at least.

Sp. 1. *Rubra.* Body red, back with a few long, and the feet with many short rufous hairs, inclining to ash-colour. Eyes blackish brown.

Dr Leach took no less than sixteen specimens of this interesting little parasite, from one tipularous insect in Devon.

Family II. Aphænorhynchi.

Mouth hidden.

Genus IV. Astoma. See Gen. VI. of this article.

Tribe II. Notostoma.

Mouth placed on the back.

Genus V. Nycteribia. Latreille, Montagu, *Lin. Trans.* vol. xi.

Pthiridium. Hermann.

Celeripes. Montagu, *Lin. Trans.* vol. ix.

Sp. 1. *Vespertilionis.*

INDEX.

Class I. CRUSTACEA.

Index.

Index.

Class II. ARACHNIDES.

CRUZ, Santa, or St Croix, is one of the three Caribbee Islands which formerly belonged to Denmark, but which was taken by the British in December 1807. This island is about 20 leagues long, and four broad, and is intersected by several small rivers. The soil is extremely fertile, but the climate is unhealthy at particular seasons of the year. The island is divided into 350 plantations, by lines drawn at right angles to each other, and each plantation contains 150 acres of 40,000 square feet. About two-thirds of the land is fit for sugar, and the other kind is employed in a less lucrative manner. Nearly forty years ago a gold mine was discovered in this island. Sixteen pounds of ore furnished eighty Danish *rix dollars* of gold, finer by two carats than the purest gold of Holland. The vein was about 10 feet deep, and 10 feet thick. It is said that a copper mine has likewise been discovered near the embouchure of the river of Santa Cruz.

This island is said to have supplied Denmark with five-sevenths of its colonial produce. It produces about 35,000 hogsheads of sugar annually, besides tobacco and fruits; about 8000 puncheons of rum, and 150 cwt. of cotton.

The official value of the exports and imports of this island, in 1809 and 1810, were,

	Imports.	Exports.
1809	L.435,378	L.84,964
1810	422,033	89,949

During the same years, the following were the principal articles imported into Great Britain:

Years.	Coffee. British Plant.	Coffee. Foreign Plant.	Sugar. British Plant.	Sugar. Foreign Plant.	Rum in Gallons.	Cotton Wool.
	Cwt.	*Cwt.*	*Cwt.*	*Cwt.*		*lbs.*
1809	297	1479	280,211	374	181,594	610,903
1810	31	—	290,933	—	236,307	174,294

The island of Santa Cruz was first occupied, in 1643, by the English and the Dutch; but jealousies having soon arisen among them, the Dutch were driven out, after a very obstinate engagement, in 1646. In 1650, the English were attacked and defeated by 1200 Spaniards, who arrived in five vessels; and the Spaniards had not possessed the island a single year, when they abandoned it to the French, who were sent out from St Christopher's for the purpose of seizing it. In the year 1696, the colonists, to the amount of 147 men, with their wives and children, and 623 blacks, left the island, after demolishing its forts, and went to St Domingo. Santa Cruz continued without colonists, and without cultivation, till the year 1733, when it was sold by France, to a company of Danish merchants, for 1,611,000 *rix dales*. It continued in the possession of this company till 1801, when it was taken by the English, by whom it was restored to Denmark in the same year of the battle of Copenhagen. The English again took it in 1807, and it has since continued in our possession.

The following was the state of the population in 1796.

Whites	2223
Free Negroes	1164
Negro slaves	25,425

CRUZ, Santa, a seaport town in the island of Teneriffe, is pleasantly situated, and has a tolerably handsome appearance. The streets are narrow, but well paved, and the houses are large and roomy. Upon the beach there is a handsome alameda, or mall, about a hundred fathoms long, shaded with several rows of trees, and formed at the expence of the inhabitants, by the late governor, the Marquis de Branciforte. A centinel stands at the entrance to prevent persons from enjoying it, and we are informed by Krusenstern, that Mr Barry, a merchant, pays one hundred piastres annually for the privilege of walking upon it. In the great square there is a well sculptured marble pillar, adorned with emblematic figures, and erected in honour of the Virgin Mary de la Candelaria. Opposite to this pillar is the fort of St Christopher's, where Lord Nelson lost his right arm in his attempt to take the town. There is also a well built pier stretching into the sea, and several level and agreeable walks and rides in the neighbourhood of the town.

Krusenstern found here abundance of grapes, peaches, citrons, oranges, melons, onions, and potatoes. He paid 90 piastres for a pipe of Teneriffe, seven for a moderate sized sheep, one for a fowl, and eightpence the pound for beef. "The general misery of the people," says this intelligent navigator, "the depravity, in the highest degree, of the other sex, and swarms of fat monks, who stroll about the streets as soon as it is dark; these are the characteristics of Santa Cruz, and strike the stranger, unaccustomed to such sights, with pity and disgust. There is no place in the world where so many horrid objects are to be seen. Beggars of both sexes, and of all ages, clad in rags, and afflicted with every kind of disgusting complaint, fill the streets, together with lewd women, drunken sailors, and lean and deformed thieves. I am almost tempted to believe that the lower class of inhabitants here have all an equal propensity to stealing. A person might fancy himself transported to one of the islands of the South Seas; for he is robbed in spite of the greatest attention and precaution. Whenever a boat came along side the ship, some theft was infallibly committed in the presence of the whole crew, and I was at last obliged to prevent any body from coming on board." See Krusenstern's *Voyage round the World*, in the years 1803, 1804, 1805, and 1806. Lond. 1813, vol. i. p. 45—50. See also Teneriffe. (j)

CRUZITA, a genus of plants of the class Tetrandria, and order Digynia. See Botany, p. 127.

CRYSTALLOGRAPHY.

Crystallography. History.

CRYSTALLOGRAPHY is that branch of science which treats of the forms and structure of crystals.

The word *crystal* (κρυσταλλος) among the Greeks, signified *ice*. It was likewise applied to what we at present call rock crystal, or quartz, because it was the opinion of the Greek philosophers that this mineral was merely water frozen by the cold, and converted into stone. Hence they conceived that rock crystal occurred only in high mountains, where the temperature is always low. But the word *crystal* in the English and other modern languages has a very different signification. It is a name given to all those regular figures (usually bounded by plain surfaces) which a great variety of bodies assume; thus, what in common language is called *sugar-candy*, is nothing else than sugar crystallized. These crystals, when examined, will be found to be four-sided or six-sided prisms, terminated at the ends by dihedral or trihedral summits. In like manner, saltpetre usually occurs crystallized in six-sided prisms, and common salt in regular cubes. Epsom salt occurs in four-sided prisms, with square bases, and alum in regular octahedrons, while the figure of the garnet is a dodecahedron with rhomboidal faces. At first the term crystal was confined to those regular bodies which have a certain degree of transparency, and therefore was conceived to be peculiar to saline bodies. But at present the idea includes nothing more than regularity of shape, and it belongs to many bodies not in the least degree analogous to salts in their nature.

The remarks made upon crystals by the ancients are not entitled to any attention: Nor are the researches of Huygens, Newton, &c. respecting the form of calcareous spar, intimately connected with our subject. The first person that attempted to form a catalogue of the different crystalline forms was Linnæus, and he made it the basis of his classification of minerals. His classification was very incomplete, and his arrangement erroneous, and in many cases absurd; yet it deserves to be mentioned, because it drew the attention of mineralogists to the subject, and constituted, in some measure, the beginning of the study. Romé de Lisle studied the subject in a very different manner. He formed a very numerous collection of crystallized minerals, examined the shape of each crystal with particular care, measured all the angles, and compared the relative sizes of the different faces. Now it happens that the same mineral very frequently occurs in a variety of shapes. Thus calcareous spar sometimes assumes the form of a rhomboidal prism, sometimes of a six-sided prism, sometimes of a dodecahedron, not to mention a great variety of other forms common to this mineral. Fluor spar occurs sometimes in cubes, sometimes in octahedrons. Quartz is sometimes crystallized in rhomboidal prisms, differing little from a cube, sometimes in six-sided prisms terminated by six-sided pyramids. To account for this variety of forms, Romé de Lisle assumed some particular form, generally the most simple he could find, which he considered as the natural shape of the mineral; and he shewed how all the other crystalline shapes of the species were derived from this primitive form, by a number of supposed truncations of its edges, or angles, or both. Thus the cube, when its right angles are sufficiently truncated, is converted into an octahedron.

Linnæus.

Romé de Lisle.

This method of Romé de Lisle was very ingenious. It served to connect together all the different crystalline forms of the same mineral, and familiarised the minds of mineralogists with the forms of crystals, and thus very much promoted the progress of mineralogy. His method was adopted by Werner, the celebrated Professor of Mineralogy at Freyberg. It is affirmed by the pupils of Werner, that the method of Romé de Lisle was in fact the method of Werner, communicated to the French mineralogist in the course of a correspondence between them. But as during the 40 years that have elapsed since the first publication of Romé de Lisle's book, no such claim has ever been publicly made by Werner, it is obvious that such assertions are entitled to no attention, and that Romé de Lisle has a right to the full credit of his method.

Werner.

But this method, though ingenious and useful, was entirely arbitrary. No reason could be assigned for the various and capricious truncations to which the primitive form was subjected. Nor could any conjecture be formed of the number of crystalline forms which were likely to occur in the same species, far less of their forms and angles. A great and fundamental improvement was made by Bergman. The first edition of his Essay was published in the year 1773, the very year in which the first edition of Romé de Lisle's Crystallography appeared. As we have never had an opportunity of seeing this first edition, we do not know how much it differs from the second edition, published in the year 1780, in the second volume of his *Opuscula*. He observed that the secondary forms of crystals always contain a nucleus of a determinate shape, which may be obtained from them by a skilful dissection. Thus calcareous spar, whatever be its shape, always yields a nucleus which is a rhomboidal prism with determinate angles. He shewed how all the secondary forms may originate from this primitive one, by the addition of slices of certain determinate shapes to each of its faces. According to Bergman, it was Assessor J. G. Gahn who first observed the rhomboidal nucleus of calcareous spar. We have been informed that it had been detected before by Mr Keir of Birmingham, who mentioned his discovery in his English translation of Macquer's *Chemical Dictionary*. We have not had it in our power to consult this translation since we were informed of the circumstance, and therefore we cannot say how far Mr Keir is entitled to the merit of the discovery.

Bergman.

This idea of Bergman was taken up by the Abbé Hauy, or rather indeed the same idea occurred to him before he had any information of what had been done by Bergman. For he informs us that his first dissertations on the subject had been presented to the Academy of Sciences before he had any information of Bergman's Dissertation, and that this dissertation was communicated to him by the Academy as likely to interest him, because it treated of the same subject with his own. Be that as it may, the subject has been prosecuted ever since by the Abbé Hauy, with the most indefatigable industry, and brought by him to an un-

Abbé Hauy.

Theory.

looked for degree of perfection. He has formed a complete theory of crystallography, and drawn up according to it a system of mineralogy, which was published in 1801. Though many unavoidable mistakes occur in this work, which have been gradually corrected since, and though many of his primitive forms are in fact hypothetical, and may turn out erroneous, yet the work must be admitted to be altogether extraordinary, to constitute an era in the science of mineralogy, and to develope a theory not only highly curious in itself, but exceedingly useful and important.

We shall divide this article into three Chapters. In the first we shall give such a popular view of the theory of crystallization, as will, we flatter ourselves, be intelligible to all our readers. In the second Chapter, we shall give the mathematical theory which is necessary for all who wish to prosecute the subject farther, or who would be able to judge of the accuracy of the labours of Hauy, or indeed to understand them. In the third Chapter, we shall give a table of the forms of the crystals of all minerals, as far as the subject has been hitherto investigated.

Chap. I.

Theory of the Structure of Crystals.

Theory of the structure of crystals.

To give a general notion of the structure of crystals, we shall describe Hauy's mechanical dissection of a six-sided prism of calcareous spar, and the discovery of the primitive nucleus, because it was the circumstance that led to the discovery of the theory of the structure of crystals, such as we have it at present. While looking over the cabinet of M. Defrance, a hexahedral prism of carbonate of lime broke off a group to which it was attached. M. Defrance made him a present of it. This crystal had a corner broken off from the base by which it had been attached to the group. M. Hauy attempted to detach similar corners from the other angles, and after some time succeeded in bringing to view its rhomboidal basis. This excited in him a movement of surprise, and first suggested to him the theory of the structure of crystals. His method of proceeding in the dissection of this crystal, may be understood from the following description.

Hauy's method of dissecting carbonate of lime. Plate CCXXII. Fig. 1.

Take a regular six-sided prism of calcareous spar, (Plate CCXXII. Fig. 1, and 2.) if you attempt to divide it parallel to the edges of the base, you will find that three of these edges, taken alternately in the upper base; for example, the edges *lf, cd, bm*, will admit of this division, while the other three of them will not. To succeed in the lower base, you must not make choice of the edges *l'f', c'd', b'm'*, which correspond with the upper edges; but the alternate edges *d'f', b'c', l'm'*. Fig. 2. These six cuts will expose to view as many trapeziums. Three of these are represented in Fig. 2; namely, the two which come in place of the edges *lf, cd*, and which are marked by the dotted lines *p p o o, q a k k*, and that which comes in place of the lower edge *d' f'*, and which is marked by the dotted lines *n n i i*.

Fig. 2.

Each of these trapeziums will have a polish and lustre, from which it will be easy to perceive that they coincide with the natural joints of the prism. You will attempt in vain to divide the prism in any other direction; but if you continue the division parallel to the first cuts, it is obvious that the size of the bases will continually diminish, while the prism itself will continually grow shorter. Just when the bases disappear altogether, the prism will be converted into a dodecahedron, (Fig. 3.) with pentagonal faces; six of which, as *ooiOe, oIkii*, are the remains of the faces of the prism, and the six others, E A I *oo, oa' kii*, are the result of the mechanical division.

Plate CCXXII. Fig. 3.

If we continue the dissection, the faces at the ends will preserve their figure and size, while the lateral faces will continually diminish in length, till at last the points *o, k* of the pentagon *oIkii* being confounded with the points *i, i*, and the same thing happening with all the other points similarly situated, each pentagon is converted into a simple triangle, as we see in Fig. 4. New slices taken off some make the triangles disappear, so that no vestige of the original prism remains. Thus we obtain the nucleus, or primitive form, (Fig. 5.) which consists of an obtuse rhomboid,† the inclination of whose faces is 105°, and the plane angles of the rhombs 101° 52′ and 78° 8′.

This example will suffice to give the reader some notion of the manner of dissecting crystals, and of obtaining their primitive nucleus. There are a great many other crystalline forms of carbonate of lime; but all of them, when properly dissected, give a rhomboidal nucleus, precisely similar to that obtained from the hexahedral prism in the preceding example. A very common crystalline shape of this mineral is the dodecahedron, represented in Fig. 6. consisting of two six-sided pyramids applied base to base. This is the crystal, the nucleus of which was found by Bergman. Nothing is easier than to detect the primitive crystal here. We have only to make cuts parallel to the edges EO, OI, and to the other edges, where the bases of the two opposite pyramids unite. This will be evident by inspecting Fig. 7. in which the primitive nucleus is represented, and the same letters are employed, as in Fig. 6. to denote the same parts of the dodecahedron.

It would be easy to multiply examples; but we conceive that the two preceding ones will suffice to give our readers an idea of the way in which the primitive nucleus may be detected, which is all that we have in view at present. All crystals do not admit of this mechanical division; but in them, what is called the cleavage, and which is in fact the direction of the natural joints of the crystal, may frequently be detected. These, assisted by the theory, as we shall see afterwards, are generally sufficient to give us a pretty near approximation, at least, to the primitive form of these bodies.

Primitive forms.

All the different primitive forms hitherto observed may be reduced to six; namely,

1. The parallelopiped.
2. The octahedron.
3. The tetrahedron.
4. The regular six-sided prism.
5. The dodecahedron with rhomboidal faces, equal and similar.
6. The dodecahedron, with triangular faces, consisting of two six-sided pyramids applied base to base.

I. The parallelopiped, as every body knows, is a solid figure, bounded by six faces parallel to each other, two and two. Thus, for example, a cube is a parallelopiped. From this definition, it is obvious that there may be an infinite number of parallelopipeds, differing

† By a *rhomboid*, in this article, is always meant a figure bounded by six equal rhombuses, parallel two and two.

Theory. Parallelopiped.

from each other in the proportional length and breadth of their faces, and in the angles which these faces make with one another. About 40 different parallelopipeds have been hitherto observed in the mineral kingdom. It may be useful to give a kind of general arrangement of them here. They may be divided into nine distinct kinds. The following description will give some notion of each of these.

1. The first is the cube. It is a well known rectangular figure bounded by six square faces, all equal to each other. Now it deserves attention, that this and all the other regular mathematical figures which occur in the mineral kingdom, constitute the primitive forms of a variety of species, while the other figures, which do not possess this mathematical symmetry, are confined to one species. The cube, for example, constitutes the primitive form of no less than 11 species of minerals; as examples may be mentioned, common salt, pyrites, galena, native gold, silver, and copper.

2. The second is a right quadrangular prism with square bases. It is a cube somewhat longer in one direction than the other. Of course the only way it can vary is in the relative lengths of two contiguous faces, the base, and one of the faces of the prism. For all the faces of the prism are, of necessity, equal and similar, being all rectangles. There are seven species which have this kind of primitive form. In four of these the prism is shorter than the square base, while in three it is longer. Meionite, wernerite, sulphate of magnesia and mesotype, have the prism shorter than the base; while in Vesuvian, chromate of lead, and titanite, it is longer.

3. The third is likewise a rectangular prism, but the base, instead of a square, is a rectangle; of course it admits of greater variation than the preceding, as both the length of the base and of the prism may vary. Yet, as far as we recollect at present, only six species of minerals have been hitherto observed, whose primitive forms belong to this variety of parallelopiped. These are apophyllite, euclase, chrysoberyl, tungsten, chrysolite, and foliated zeolite.

4. The fourth is likewise a rectangular prism, but the base is a rhomb. Hence it is nearly in the same circumstances with the second kind; the square in it being a rhomb in this kind. The primitive forms of sulphate of barytes, sulphate of strontian, arsenical pyrites, mica and granatite. There may be others that belong to this kind of form, though we do not at present recollect them.

5. The fifth kind is likewise a rectangular prism; but the base is an oblique angled parallelogram. It bears the same relation to the third kind that the fourth does to the second. We recollect at present only three species of minerals that have this primitive form; namely, pistazite, axinite, gypsum, and borax. They differ from each other of course in the relative proportions of the faces, and in the angles of the base.

6. The sixth kind is an oblique angled prism, the base of which is a rhomb. Hornblende, actinolite, augite and grammatite, are species, which have this kind of primitive form.

7. The seventh kind is an oblique angled prism, the base of which is an oblique angled parallelogram. Felspar and sulphate of copper belong to it. If there be any other minerals that have this primitive form, we do not recollect them at present.

8. The eighth kind is a rhomboid with an obtuse summit. The distinction between this and the succeeding kind is rather artificial than real. But it deserves attention, because it is useful in the theory, and facilitates the description of crystals. By a rhomboid, in crystallography, is meant a figure bounded by six equal and similar rhombs. So that it is nothing more than an oblique angled cube, or a cube twisted a little awry; and in some of the species, the deviation of the rhomboid from the cube is not very evident to the eye. This is, in some measure, the case with the primitive figure of quartz, and still more with that of chabasie, to which the name of cubic zeolite, on that account, has been often given. Now, if you examine the eight solid angles of any of the rhomboids belonging to this kind, you will find that two of them, which are opposite to each other, differ from the other six. They are composed each of three obtuse plain angles meeting together in a point; whereas the six others are formed of two acute and one obtuse angle. The line joining these obtuse solid angles is called the *axis* of the crystal, and the angles themselves constitute the *summits* of the crystal. The axis is the *shortest* line joining any two opposite angles in the respective rhomboids. The following species belong to this kind of parallelopiped. Calcareous spar, red silver ore, quartz, chabasie, dioptase or copper, emerald, and tourmaline.

9. The ninth kind is a rhomboid with an acute summit. If you examine the eight solid angles of these rhomboids, you will find two of them to differ from the other six. They are formed by the inclination of three acute plain angles to each other, whereas the other six are composed of two obtuse and one acute plain angle. The line joining these two acute and opposite solid angles, is called the axis of the crystal, and the angles themselves are called the summits. This axis is the *longest* line joining any two opposite angles of the crystal. The species of minerals belonging to this kind of rhomboid, are sulphate of iron, corundum, and oligiste iron ore. The primitive form of the two last differ but little in appearance from a cube.

Octahedron.

II. The second primitive form is the octahedron. The simplest way of forming a notion of this figure, is to conceive two four-sided pyramids applied base to base; thus united they form the octahedron. There are about 30 species of minerals which have the octahedron for their primitive form. They may be divided into four kinds.

1. The regular octahedron. In it the triangular faces are equilateral and equiangular, and, of course, the base of the two pyramids is a square. A considerable number of minerals have the regular octahedron for their primitive form. We recollect at present 11 different species. The following are their names: alum, salammoniac, fluor spar, diamond, spinel, magnetic iron ore, native antimony, native bismuth, red copper ore, native amalgam, muriate of copper.

2. Octahedron composed of two pyramids, having rectangular bases applied base to base. Each triangular face, of course, is isosceles, the two angles at the base being equal, and the angle at the summit different. It may be either acute, rectangular, or obtuse, according to the length of the rectangular base of the pyramids. The faces are equal and similar, four and four. The following species have this primitive form: carbonate of lead, sulphate of lead, calamine, topaz, chiastolite, nitrate of potash, and perhaps also arragonite.

3. Octahedron composed of two pyramids having a square base. The pyramids, in general, are very low, when compared with the size of the base, though this

Theory.

is not always the case. In anatase, for example, they are long, and of course the solid angle at their summit is composed of very acute plane angles meeting at a point. The following species of minerals have this primitive form: tinstone, zircon, molybdate of lead, mellite, harmolome or cross-stone, and anatase.

4. Octahedron composed of two pyramids terminated by a rhomboidal base. They vary from each other in the height of the pyramids, and the angles of the rhomb constituting the common base of the pyramids. Sulphur, carbonate of soda, realgar, and sphene.

Tetrahedron.

III. The regular tetrahedron is a figure bounded by four equilateral and equiangular triangles; or it may be conceived as a three-sided pyramid terminated by a triangular base. There are but few minerals which have this figure for the primitive form of their crystals. At present we recollect only grey copper ore, and copper pyrites.

Regular six-sided prism.

IV. The regular six-sided prism is a prism composed of six equal rectangles, and terminated at each extremity by a regular hexagonal base. They differ from each other in the height of the prism compared with the diameter of the base. The following species of minerals have this primitive form: apatite, carbonate of strontian, emerald, cinnabar, sulphuret of copper, pinite and sommite.

Rhomboidal dodecahedron.

V. The rhomboidal dodecahedron is a solid bounded by twelve equal rhombs. It is a beautiful, but not very common primitive form. Every body must have observed, that it is the shape which garnets usually affect. We recollect no mineral species, except garnet and blende, which have the rhomboidal dodecahedron for the primitive form of their crystals.

Triangular dodecahedron.

VI. The last primitive form is the triangular dodecahedron. It may be conceived to consist of two six-sided pyramids applied base to base. The common base, of course, is a regular hexagon. This is by no means a common primitive form. Carbonate of barytes and phosphate of lead are the only two species that we recollect in which it occurs. In the first of these, the pyramids are long compared to the diameter of the base; in the second, they are short.

From the preceding account of the primitive forms of crystals, it is obvious that two of them, namely, the parallelopiped and the octahedron, are by far the most common, and include by far the greatest number of primitive forms. The six-sided prism is likewise not uncommon. But the other three primitive forms, namely, the tetrahedron, the rhomboidal dodecahedron, and the triangular dodecahedron, are comparatively insignificant, occurring only each in about two species. However, as these species happen to be very well marked and important, they could not be passed over without impropriety.

After we have obtained the primitive crystal of a mineral by mechanical division, it very frequently happens that we can still continue the mechanical division, either by cutting off slices parallel to the faces of the primitive crystal, or in some other direction, when any natural joints become evident. If we continue the mechanical division of calcareous spar by cutting off slices parallel to the faces of the crystal, the only directions that admit of mechanical division, it is obvious that the figure of the substance will continue the same. It will diminish in size; but will experience no other change. Suppose, on the other hand, that we continue to cut slices from a six-sided prism, by cuts parallel to the faces of the prism, the consequence would be that we would divide the whole prism into a number of triangular prisms. This will be evident to the eye, by inspecting Fig. 8. which represents the basis of a hexagonal prism, divided into triangular prisms by such continued divisions.

Plate CCXXII. Fig 8.

Sometimes a parallelopiped admits of divisions in other directions, besides those parallel to the faces. Suppose the rhomboid AA′KH, Fig. 9. divisible both in the direction parallel to the six rhombs which constitute its faces, and likewise in planes passing through the oblique diagonal AO, the axis A′A and the edge A′O comprehended between the diagonal and the axis, the consequence of such a division would be, that the rhomboid would be separated into six tetrahedrons, as any person may satisfy himself by a little consideration. These tetrahedrons are represented in the Figure surrounding the original rhomboid; and, to aid the conception, the same letters are employed to denote the same parts in the rhomboid, and in the tetrahedrons into which it is conceived to be divided.

Fig. 9.

These examples of the ultimate changes which may be produced upon the primitive crystals by mechanical division, will be sufficient to give the reader an idea of the subject. Hauy conceives, that, by these divisions, we obtain the form of the integrant molecule, or of the ultimate integrant atom of the mineral in question. No proof can be advanced in proof of this conjecture, except the impossibility of altering the form, how far soever we carry on divisions, and the obvious consequence, that, if these divisions be carried far enough, we must at last reduce the crystal to its integrant particles. The subject is not of much importance, as far as crystallography is concerned; because the theory of crystals is not in the least affected either by its truth or its falsehood; and no use whatever is made of the integrant molecules in any part of the theory. We must acknowledge, that the reasoning of the Abbé Hauy appears to us plausible. It may therefore be adopted, at least for the present, without any inconvenience.

Integrant molecule.

That all minerals have integrant molecules of a determinate shape, and that this shape never varies in the same species, we conceive to be incontrovertible. M. Delametherie, indeed, has endeavoured to prove, that the integrant molecule varies in its form in the same species; but his arguments are founded entirely upon the opinion of Berthollet, that substances are capable of uniting indefinitely in a great variety of proportions,—an opinion entirely refuted by all the phenomena of chemistry, and which no chemist can well maintain, without refusing his assent to the best demonstrated truths in the science. We do not therefore think it necessary to enter into any examination of the arguments advanced by Delametherie in support of his opinion, as they are arguments which no chemist can admit, and which, of course, are not calculated to produce conviction.

Hauy has found, that the integrant molecules of all crystals, supposing them capable of being discovered by mechanical division, may be reduced to three species; namely, the tetrahedron, the triangular prism, and the parallelopiped. Now, it deserves attention, that these are the three simplest conceivable solid bodies, being bounded respectively by four, five, and six faces,—the smallest number of faces by which a solid body can be bounded. It is needless to observe, that each of these figures is capable of a good many varieties, by alterations in the proportions, and the angles of the respective faces.

It may be worth while to give a few examples of the

Theory.

different minerals in which these various integrant molecules occur. The tetrahedron, varying, of course, in its respective angles and dimensions, is the integrant molecule of quartz, nitrate of potash, topaz, chiastolite, calamine, carbonate of lead, sulphate of lead, phosphate of lead. The triangular prism, equally various in its dimensions, is the integrant molecule of the emerald, augite, axinite, granatite, pinite, sommite, vesuvian, mesotype, sulphate of magnesia, sulphate of barytes, sulphate of strontian, appatite, cinnabar, sulphuret of copper, titanite, chromate of lead. The parallelopiped is so common, that numerous examples are unnecessary. We may mention common salt, pyrites, calcareous spar, as familiar instances.

When these integrant molecules happen to be regular mathematical figures, it is not uncommon to find them belonging to more than one species. Thus the cube is the integrant molecule of common salt and of pyrites; but when this regularity does not exist, we find every species have an integrant molecule of its own, distinct in shape from that of every other species.

After having determined the primitive forms of crystals, the next point is to determine the laws which the integrant molecules observe in arranging themselves, so as to produce the great variety of secondary crystals, which belong to every mineral species. The Abbé Hauy has shewn, that these secondary forms may be accounted for, and the structure subjected even to calculation, by supposing that layers of integrant molecules arranged so as to form plates, are applied successively to all the faces of the primitive crystal, while each successive plate diminishes in size by the abstraction of a determinate number of integrant molecules (or parallelopipeds), either parallel to the edges, or the diagonals of the faces, or in some other direction. We shall endeavour to make this structure, which constitutes the basis of the theory, intelligible to our readers by some simple examples. The decrements may be either parallel to the edges, to the diagonals, or in an intermediate direction between the two. It will be proper to give examples of each of these decrements.

1. *Decrements on the Edges.*

Decrements on the edges.

Let us suppose that the primitive form of a mineral species is the cube; but that secondary crystals of the same species likewise occur, having the form of the rhomboidal dodecahedron. How is this dodecahedron derived from the cube? Let us suppose, as may be done in every case, that the integrant molecule of this species is a cube; it follows that the primitive cubic crystal is formed by the congeries of a number of cubes. Suppose these cubes of such a size that an edge of the primitive crystal is composed of seventeen of these small cubes applied side by side. Of course every face of the primitive crystal will be composed of 289 squares, consisting of the bases of so many integrant molecules. According to this supposition, the primitive crystal will be a congeries of 4913 little cubes. Let us now suppose, that a square, consisting of the thickness of one integrant molecule, be applied to every face of the primitive crystal; but that, instead of being of the size of the face of that crystal, it be less than it by a single row of integrant molecules all round, so that its side, instead of 17 little cubes, contains only 15; and of course it contains only 225 little cubes instead of the 289 that go to the formation of the face of the primitive crystal. Upon each of these first plates applied all round to every face, let another plate be applied similar to the first, but less than it by a row of integrant molecules, so that the side contains only 13 squares, and the whole plate only 169 squares. Let six other plates be applied in succession to each of the faces, diminishing by a row of little cubes all round, so that the sides of each consist of 11, 9, 7, 5, 3, 1, squares, respectively. It is obvious, that, by this process, we have raised upon each of the six faces of the cube a four-sided pyramid, the faces of which, instead of being smooth, will, by their constant diminution in bulk, represent the steps of stairs. Each of these pyramids having four faces, constitute small 24 triangular faces; so that, by this process, we have converted the cube into a new crystal. It would seem, at first, that this new crystal ought to have 24 triangular faces; but a little consideration will satisfy us, that the two adjacent triangular faces, in each pyramid, are in the same plane, and form together a rhomb; so that, in fact, the cube has been converted into a rhomboidal dodecahedron. Fig. 10. represents the cubic nucleus, with the pyramids raised upon three of its faces; and Fig. 11. represents the rhomboidal dodecahedron formed in this manner. This is an example of a secondary crystal formed by decrements on the edges of the plates. Suppose us in possession of such a crystal, it is easy to see how, by mechanical division, the cubic nucleus might be extracted. We would have only to cut off all the solid angles formed by four plain angles, by slices parallel to the shorter diagonals EO, OI of the rhombs.

Plate CCXXII. Fig. 10. Fig. 11.

In the preceding example, each plate was only of the thickness of one integrant molecule, and the decrement was only one row of integrant molecules all round; but we might have supposed the thickness of the plates to have equalled two or more integrant molecules, and the decrements might have been equal to two rows of integrant molecules, or more, at once. In that case, the form of the secondary crystal obtained would have been different from the rhomboidal dodecahedron.

Decrement in breadth.

It will be necessary here to explain the meaning of two terms, which we will have occasion to employ frequently hereafter. *Decrement in breadth* is used when the thickness or height of the plate is only equal to one integrant molecule; but one, two, three, &c. rows of molecules all round, we conceive to be abstracted from the breadth of each succeeding plate. *Decrement in height* is used when the plates only diminish by one row of integrant molecules in breadth, but their height may be equal to two, three, &c. molecules. In such cases, the decrement is expressed by saying, that it takes place by two, three, &c. rows in height.

Decrement in height.

It will be worth while to give another example of a secondary crystal formed by decrements on the edges of the faces. The primitive form of pyrites is a cube; but, among a great variety of secondary crystals, there is one which occurs in the form of a rhomboid with pentagonal faces. This crystal is represented in Fig. 12. where the cubic nucleus may likewise be seen. From the inspection of that Figure, it will be obvious, that, instead of a four-sided pyramid, as in the former case, a kind of wedge is formed upon each face of the cubic nucleus, which may be conceived to be the pyramid elongated in one direction. This wedge upon one of the faces of the cube, is represented by OO′ *t n* I I′. In this case, the decrements may be conceived to take place by two ranges in breadth between the edges OI and AE, I I′ and OO′, EO and E′O′; and in the same manner upon the opposite faces; while, at the same time, they take place by two ranges in height between

Fig. 12.

the edges EO and AI, OI and O′I′, OO′ and EE′. We see that these decrements take place upon the different faces of the cube in three directions, which cross each other at right angles. The decrement, by two ranges in breadth, tending to produce a face more inclined than that which results from a decrement by two ranges in height, the consequence must be, that the structure of plates does not terminate in a point, as in the first example, but in a wedge. The lines *p q*, *t n*, (Fig. 12.), represent the summits of two of these wedges. If we compare these summits *p q*, *t n*, with the summit *r s* of the wedge which covers the face EOO′E′ of the cubic nucleus, it will be easy to perceive that these three lines are perpendicular to each other respectively. Fig. 13. represents the cubic nucleus with wedges raised upon two of its contiguous faces by means of plates pursuing decrements according to the law above described. The same letters are applied to the same parts of the crystal in Figs. 12. and 13. At *s*′ is seen the extremity of the summit of a third wedge raised upon a third face of the cube. Each trapezium, such as O *p q* I (Figs. 12 and 13.), being in the same plain with the triangle O *t* I belonging to the adjacent wedge, both together conspire to form the pentagon *p* O *t* I *q*, so that the secondary crystal formed by these decrements, instead of 24 faces, has only 12 pentagonal faces, and is therefore a dodecahedron as well as the first example, but a dodecahedron of a different kind.

Plate CCXXII. Fig. 12.

Fig. 13.

We shall give a third example of these kind of decrements, because it contains something peculiar in it, but which often takes place in the formation of secondary crystals; and it is requisite that the reader should be aware of it. The dodecahedron represented in Fig. 6. is a secondary crystal of calcareous spar. In it the edges EO, OI, IK, &c. where the two opposite pyramids join, coincide with the edges of the primitive nucleus, as may be perceived by inspecting Fig. 7. The decrements set out from these edges, and do not take place at all upon the other six edges of the primitive nucleus EA, AI, AG, OA′, &c. Now, it is easy to conceive, that the edges of the plates laid upon the primitive nucleus, form, by their sum, as many triangles E *s* O, I *s*′ O, E *s*′ O, &c. resting upon the edges from which they set out; and as these lines are six in number, there will be 12 triangles, six above, and as many below; and all these triangles will be scalene, in consequence of the obliquity of the edges from which the decrements set out.

Fig. 6.

Fig. 7.

With respect to the other edges of the plates of superposition, they will be so far from experiencing any decrement, that they will, on the contrary, augment, because they must always remain contiguous to the axis of the crystal, just as happens when the primitive crystal increases in size by the superposition of new plates, without undergoing any change of form. It is the province of mathematics, combined with observation, to determine the law of decrement upon which this dodecahedral form depends. If we suppose a decrement of one range, it may be demonstrated that the two faces produced on each side of the edge from which the decrement set out, will be in the same plain, and parallel to the axis of the primitive crystal, circumstances which do not suit the present case. If we suppose a decrement of two ranges in breadth, it may be demonstrated that the result will be a dodecahedron similar to the one which we are considering. Hauy has pitched upon this law in the present case, influenced by several very plausible geometrical considerations, which, however, we are afraid will not be found to hold so accurately as he supposed, seduced by an inaccurate measurement of the angles of the primitive crystal of calcareous spar. Fig. 14. represents one of the pyramids of this dodecahedron formed by the superposition of plates following the law of decrements by two ranges of particles. The line E *s* represents an edge of this pyramid such as it appears to the eye, E *s* such as it really exists; but the distance *s s*′ is not sensible, in consequence of the extreme minuteness of the size of the intermolecules, by the abstraction of which the pyramids are formed. The same reason prevents the channels or steps of stairs upon the pyramids from being sensible. Though in some cases, when secondary crystals are formed with great rapidity, these channels may be perceived by the naked eye.

Plate CCXXII. Fig. 14.

We conceive the preceding illustrations are sufficient to explain what is meant by the decrements on the edges of crystals. Let us now proceed to the second kind of decrement.

2. *Decrements on the Angles.*

Decrements on the angles.

Decrements on the edges, which have been just described, are not sufficient to account for all the diversity of forms which secondary crystals assume. To give an example; mineral species, the primitive form of whose crystals is the cube, are found crystallized in secondary forms, some of which are rhomboidal dodecahedrons, and others regular octahedrons. The formation of the rhomboidal dodecahedron has been explained above, by means of decrements on the edges. At first sight, it would appear that the octahedron might also be derived from the cube by decrements on the edges. We have only to take two opposite faces of the cube, and to suppose a four-sided pyramid raised upon each by means of decrements on the edges of the plates successively applied. While this is going on upon these two faces, we may suppose that the other four faces of the cube remain unaltered. Each of these two pyramids may be supposed to prolong itself downwards till they meet. The consequence would be an octahedron enveloping the cubic nucleus; but it may be demonstrated, that no law of decrement whatever could in this case form an octahedron with equilateral triangular faces, which is the case with the octahedron derived from the cube. Besides, if we have recourse to mechanical division, in order to obtain the cubic nucleus from this kind of octahedron, we shall find that the solid angles of the cube coincide with the central points of the eight faces of the octahedron, which could not be the case if the octahedron had been formed in the way we have been supposing. But if we suppose the decrements to take place parallel to the diagonal of the faces of the cube, all difficulty vanishes; we obtain the regular octahedron without difficulty. Such decrements are called *decrements on the angles*.

Let OI I′O′ (Fig. 15.) be one of the faces of the cubic nucleus, divided into a number of little squares, which are the bases of as many molecules. We may conceive these molecules arranged in two different ways; they may be parallel to the edges, as is the case with the molecules *a*, *n*, *q*, *r*, *s*′, *t*′, *v*′, *z*′, *s*′; or they may be arranged in the direction of the diagonals, as is the case with the molecules *a*, *b*, *c*, *d*, *e*, *f*, *g*, *h*, *i*, and likewise with the molecules *n*, *t*, *l*, *m*, *p*, *o*, *r*, *s*, and likewise with the molecules *q*, *v*, *k*, *u*, *x*, *y*, *z*. One of these rows of molecules is represented separately in Fig. 16.

Fig. 15.

Fig. 16.

The molecules parallel to the edges of the square

Theory. touch by one of their faces, and the ranges themselves are simply placed contiguous to each other. The molecules parallel to the diagonals touch only by an angle, and the ranges are indented into each other. When secondary crystals are formed by this last kind of decrement, the new faces are not merely channelled, as happens in the case of decrements on the edges; they are all bristled with points, which being exceedingly minute, and all in the same plane, escape the eye, so that the faces appear smooth.

Having thus explained the meaning of the terms, let us illustrate this kind of decrement by an example; and we cannot get a better than the formation of a regular octahedron from a cubic nucleus. This is the consequence of the superposition of plates upon each face of the cube with decrements of a single range of molecules on the angles. Let AEOI (Fig. 17. A) be one of the faces of the cubic nucleus subdivided into 81 little squares, which are the bases of so many molecules, of which the face is conceived to be composed.

Plate CCXXII. Fig. 17. A.

Fig. 17. B. Fig. 17. B, represents the first plate of superposition, which ought to be placed above AEOI (Fig. 17. A) in such a manner, that the point e' corresponds with the point e; the point a' with the point a; the point o' with the point o; and the point i' with the point i. It is obvious, from this manner of placing it, that the squares Ee, Aa, Ii, Oo, (Fig. 17. A), remain uncovered; which is the initial effect of the decrement on the angles. We see likewise, that the edges QV, PN, LC, FG, (Fig. 17. B), exceed by a range of molecules the edges EA, EO, OI, IA, (Fig. 17. A). This is necessary to prevent re-entering angles, and is merely the consequence of the increase of size of the crystal, without any change of form in these quarters.

Fig. 17. C. The upper face of the second plate of superposition, is represented by BKHD (Fig. 17. C). It must be applied to the first plate in such a manner, that the points e'', a'', i'', o'', coincide with the points e', a', i', o', (Fig. 17. B), which leaves bare another row of molecules parallel to the diagonal. This plate also increases by a row of molecules at all its edges B, K, H, D, for the same reason as the first plate did.

The figure of these plates of superposition, which at first was an octagon, has now become a square. It is no longer necessary to continue the addition of rows of molecules at the edges; so that the succeeding plates retain the square shape, but constantly diminish in size, in consequence of the abstraction of a row of molecules from each edge parallel to the diagonal of the face of the cubic nucleus. These different plates are represented by Fig. D, E, F, G, H, and I, in each of which the small accented letters denote the points of the plate that coincide with the same letters in the preceding plate. Eight plates are necessary, as appears from the Figure, and the last of them consists only of a single molecule.

Fig. 17. D, E, F, G, H, I.

If we suppose the same number of plates, of the same form, to be applied successively upon each face of the cubic nucleus, it is obvious that we raise upon each of the six faces of the cube a four-sided pyramid. Hence it would appear, at first sight, that the secondary crystal would have 24 faces. Each of these faces will have four edges, as must appear evident upon a little consideration, and will have the form represented in Fig. 18. in which the angle o is conceived to coincide with the angle O of the cubic nucleus, and the diagonal $t\,x$ represents the edge HK (Fig. 17. C) of the plate BKHD. The triangle $t\,o\,x$, being composed of those plates of superposition, the edges of which undergo an increment, will be much shorter than the triangle $t\,s\,x$ formed of those plates of superposition whose edges undergo no increment; because the number of the first is much smaller than that of the second, they being to each other as 2 to 6.

Fig. 18.

Thus the surfaces of the secondary crystal is composed of 24 quadrilateral faces, arranged, three and three, round each angle of the cubic nucleus. But as in the decrements, by one range of molecules on the edges, the faces produced on both sides of the same edge are in the same plane, so in decrements by one range of molecules on the angles, the faces formed on the three sides of each angle are in the same plane. This plane is represented in Fig. 19. where the three quadrilaterals surrounding the angle of the cube o, coincide to form the equilateral triangle $m\,n\,s$. Thus the faces of the secondary crystal are reduced to eight equilateral triangles, and of course the figure is that of the regular octahedron.

Plate CCXXII. Fig. 19.

If these decrements were to stop before they terminated in a point, the consequence would be, that faces would remain parallel to the original faces of the cube. The consequence would be, that the crystal would have fourteen faces, eight those of the octahedron, and six those of the cube; so that it would at once have the form of the cube and of the octahedron. Nothing is more common than to find such crystals both in pyrites and galena.

If the decrements were more rapid, as, for example, if two or more ranges of molecules were abstracted, then the three trapezoids $s\,t\,o\,x$, $m\,t\,o\,r$, $n\,r\,o\,x$, (Fig. 19.) formed round the same solid angle of the nucleus, would not be in the same plain, but would be inclined upon each other, and the secondary crystal would have 24 trapezoidal faces.

As another example of this kind of decrement, let us take the rhomboid, Fig. 20. which differs somewhat from a cube by having acute angles. Let us suppose that the plates applied upon all the faces of this rhomboid suffer decrements only at the angles contiguous to the summits A, O', and that these decrements take place by two ranges; then, instead of 24 faces, only six would be formed: and if we conceive these prolonged till they meet each other, they would compose a very obtuse rhomboid, which would be the secondary crystal. Fig. 21. represents such a rhomboid, with its primitive nucleus enclosed. We see that its summits A, O' coincide with the summits of the primitive rhomboid, from which the decrements commenced, and that each of its faces, as A $e\,o\,i$, corresponds with one of the faces AEOI of the nucleus, so that the diagonal which passes through the points e, i is parallel to the diagonal EI of the face of the nucleus, and only somewhat more elevated. This kind of crystal is found among the secondary crystals of *Oligiste iron ore*.

Fig. 20.

Fig. 21.

The decrements which take place upon the angle, whether superior or inferior, are susceptible of different variations, respecting which, it may be proper to make some observations before we proceed farther. Let G g (Fig. 1.) be any rhomboid whatever, the summits of which are S, s. Let Sg'' s G$''$ (Fig. 2.) be a quadrilateral figure formed by cutting through the rhomboid G g in the direction of a plain formed by the two oblique diagonals Sg'', sG$''$ (Fig. 1.) and the edges SG$''$, $s\,g''$ contained between these two diagonals. This quadrilateral figure, termed by Hauy the principal section of the rhomboid, is divided in the Figure into a number of similar small quadrilaterals, representing the principal section of as many molecules. Let SGg''G'

Plate CCXXIII. Fig. 1. Fig. 2.

Theory.

Plate CCXXIII. Fig. 3.

(Fig. 3.) be the face of the rhomboid (Fig. 1.) marked with the same letters, subdivided into the bases of the molecules of which it is composed. If we suppose that the angle g'' undergoes a decrement by a single row of molecules, the small rhomboid represented by $o\,n\,z\,g''$ will be wanting; hence, it is obvious, that the edge of that plate will have the direction $o\,z$, and that the distance between the angle g'', from which the decrement sets out, and the edge $o\,z$, will be measured by the semidiagonal $r\,g''$ of a molecule. If the decrement takes place by two ranges, the edge of the first plate of superposition will correspond with $c\,d$, and the distance between it and the angle g'' will be measured by the diagonal $g''\,n$ of a molecule. From this we may conclude, that, in general, in decrements on the angles, the distance between one plate and the succeeding one, which is the same with that of the angle from which the decrements began, and the first plate of superposition, is equivalent to as many semidiagonals of a molecule as there are ranges taken away; while, in the case of decrements on the edges, the distance between two successive plates is equivalent to a number of diagonals equal to that of the molecules taken away.

This being understood, let us suppose a decrement of two rows upon the angle g''. In that case, the quadrilateral $n\,e\,a\,p$ (Fig. 2.) being a section made on the first plate of superposition, the edge of that plate in which the decrement takes place will coincide with en, since $g''n$ is the same diagonal as in Fig. 3. Therefore, if we draw the straight line $g''eh$, it will coincide with the face produced by the decrement. But in this case $g''h$ is parallel to the axis S s, as may be easily demonstrated by the assistance of mathematics. Hence it follows, that the secondary faces constitute the faces of a prism.

If the decrements went on more rapidly, if they took place, for example, by four ranges, in which case the edge of the first plate of superposition will coincide with the line $y\,g$, then the line $g''q$S$'$ indicates the position of the secondary faces. We see that they rise above the nucleus, and form the surface of a rhomboid more acute than this nucleus. If, on the other hand, the decrements took place in height, then the line $ug''s'$, which we suppose to indicate the secondary faces produced, would incline towards the inferior portion of the axis. Hence, it is obvious, that the faces of the secondary crystal (still a rhomboid) would incline in the opposite direction of the primary faces.

The hypothesis of a decrement by two ranges in height, gives, in this case, a remarkable result; the secondary crystal is precisely similar to the primitive. Hauy has made it probable that such secondary crystals exist both in quartz and tourmaline.

Let us pass to the superior angle S, and let us suppose at first a single range of molecules taken away. If from t, the centre of the equal diagonal Sp, we draw $t\,x$ parallel and oblique to $p\,a$, this line will coincide with the edge of the first plate of superposition, since the distance between the angle S and the edge is equal to a semidiagonal of a molecule. Hence the line S$x\,h$ will coincide with the secondary face produced by the decrements, which is obviously perpendicular to the axis.

A more rapid decrement, as by two ranges in breadth, would produce faces inclined as the line S $a\,i$ is; that is to say, that the secondary crystal would be a rhomboid, inclined as the nucleus, and more obtuse. If the decrement takes place in height, then the secondary faces produced, one of which corresponds with the line KS m, will incline to the other side of the axis; hence the secondary rhomboid will have a position the reverse of the primary.

Theory.

These observations and examples we conceive sufficient to make the nature of the decrements on the angles obvious to every reader who takes the trouble to consider the subject. But there is still other kinds of decrement which remain to be explained.

3. *Mixed Decrements.*

Mixed decrements.

This name is applied to those decrements in which the number of ranges taken away in breadth and height give ratios, the two terms of which surpass unity. As, for example, decrements by two ranges of molecules in breadth, and three in height, or by three ranges in breadth and two in height, &c. It is easy to see that the theory may be with facility reduced to that of decrements, in which there is only one row of molecules taken away in one of the two directions.

4. *Intermediate Decrements.*

Intermediate decrements.

We have seen, that in the case of a decrement by one row of molecules round the same solid angle, the three faces produced are always in the same plain, and that, in that case, it is only necessary to consider the effect of the decrement with respect to one of the plain angles which concur to the formation of the solid angle, conceiving this effect to be prolonged over the neighbouring faces. In that case, the decrements on these last faces are considered as *subsidiary*, to favour the action of the principal decrement.

In general, whenever the solid angle of a primitive crystal undergoes decrements which tend to produce a face in its place, whatever the law may be to which we reduce the production of that face, there are always auxiliary decrements, the concurrence of which is necessary, in order that the new face may be of the requisite magnitude. Now, when the decrement which we consider in preference takes place, by two ranges of molecules, or by a greater number, the auxiliary decrements in continuity with it follow a peculiar law, which it is necessary to explain.

Plate CCXXIII. Fig. 4.

Let AA$'$ (Fig. 4.) be a parallelopiped of any kind which undergoes a decrement by two ranges on the angle EOI of its base AEOI. It is obvious that the edges of the plates of superposition will have the directions $b\,c$, $r\,s$, parallel to the diagonal EI, and so situated that there will be upon the sides OE, OI two rows of molecules comprehended between the angle O and the line $b\,c$, and likewise between $b\,c$ and $r\,s$. But, as has been already said, the plates applied upon the adjacent faces IOA$'$K, EOA$'$H undergo likewise auxiliary decrements, which continue the effect of the decrement upon the angle EOI. But such, in this case, are the effects of these decrements, that the edges of the plates applied upon IOA$'$K have the directions $c\,g$, $s\,t$; and those of the plates applied upon EOA$'$H the directions $b\,g$, $r\,t$. For since the lower edge of the first plate applied upon AEOI coincides with bc, and the height of this plate corresponds to that of a single molecule, a little attention will satisfy us that the plane $b\,c\,g$, which on one part coincides likewise with bc, and on the other separates from the base AEOI, by a quantity measured by O g the height of a single molecule, is necessarily parallel to the face produced by the decrement. The same holds with the plane $r\,t\,s$. From this it follows, that if we suppress

Theory.

the part situated above rts, we will have a solid on which the face rts will represent the effect of decrement that we are considering.

Now the directions cg, st of the plates applied upon the face IOA′K (and the same may be said of the face EOA′H) in consequence of the auxiliary decrements, are neither parallel to the edge, nor to the diagonal of the face, but intermediate between the one and the other. This want of parallelism will become still greater if we suppose the decrements upon the angle of the base EOI to take place by 3, 4, &c. ranges. This is the kind of decrement to which the name of *intermediate* has been given. It is obvious that it may take place in an infinite number of different directions, according as it deviates more or less from its two limits, the parallelism with the edge, and the diagonal of the face.

Plate CCXXIII. Fig. 4.

In cases similar to those of Fig. 4. we avoid the complication introduced by these intermediate decrements, by supposing them comprehended under the principal decrement. But certain crystals exist, in which all the three decrements round the same solid angle are intermediate. In such a case, the simplest of the three is chosen as the principal decrement, and the other two considered as auxiliary. Fig. 5. represents a case of this kind; cn, which is the edge of the first of the plates applied upon AEOI, is so situated, that on the side of OI there are three molecules subtracted; while on the side OE there is only one: np, which is the edge of the first plate applied upon IOA′K, indicates three molecules subtracted from OI, and two from OA′; cp, which is the edge of the first plate applied upon EOA′H, shews the subtraction of two molecules on OA′, and only one on OE.

Fig. 5.

It is easy to see that the decrements take place relatively to the different faces situated round the angle O, as if the molecules that compose the different plates of superposition, being united invariably several together, compose other molecules of a higher order, and as if the subtraction took place by single ranges of these compound molecules. Thus there will be on the base AEOI a decrement of triple molecules by two ranges in height, since on one part the quadrilateral figure $cOnz$, which represents the base of a compound molecule, is equivalent to the bases of three simple molecules; and, on the other, the line Op, which corresponds to the height of a plate of superposition, is equivalent to the height of two simple molecules. It is easy to conceive, likewise, that the decrement relative to the face EOA′H takes place by two ranges in height of double molecules, because $cOpx$ contains the bases of two simple molecules, and On is equal to the length of three simple molecules. In the decrement which takes place upon IOA′K there is a subtraction of one row of molecules triple in one direction, and double in the other.

Among these three decrements, the one which it appears most natural to adopt as the principal, is the second, which takes place upon the face EOA′H, because it is the one whose direction deviates the least from that of the diagonal EA′; or because it takes place by double molecules, which is a more simple decrement than the other two.

Suppose intermediate decrements on the two lateral angles G, G′ (Fig. 3.) of the face of a rhomboid, and that these decrements take place by ranges of double molecules, that is to say, parallel to the lines um, xy, $u'm'$, $x'y'$. It is evident that these decrements will produce above each rhomb of the primitive nucleus, such as SGg''G′, two faces, which commencing at the angles G, G′, will converge towards each other, and come in contact in a line situated above the diagonal Sg'', but inclined to that diagonal; so that the complete result of the decrement will be the formation of twelve faces disposed six and six towards each summit. Fig. 6. represents one of these solids, with its nucleus inscribed. It is a variety of calcareous spar which sometimes occurs. The lines $a\,b\,a'$ shew the direction of a fracture parallel to the face Gg''G′S of the primitive nucleus. It appears from this Figure that the nucleus does not touch the secondary crystal, except by its lateral angles, which are situated in the edges BS′, Ds', Cs', &c. while in the dodecahedron of Bergman, represented in Figs. 6. and 7, and called by Hauy, *Chaux carbonaté metastique*, the lateral edges of the nucleus coincide with those edges of the secondary crystal that constitute the common basis of the two pyramids, as is evident from inspecting Fig. 7.

Plate CCXXIII. Fig. 6.

Plate CCXXII. Figs. 6, 7.

Hitherto intermediate decrements have been observed only in a small number of instances, but they lead to forms as simple as the other, and give some curious results, which deserve to be studied in a mathematical point of view, without any reference to crystallography.

5. *Compound secondary forms.*

Compound secondary forms.

Simple secondary forms are those which proceed from a single law of decrement, the effect of which covers and conceals the nucleus, which only touches the surface of the secondary crystal by certain angles or edges. *Compound secondary forms* are those which are produced by several simultaneous laws of decrement, or by one law which has not reached its limit, so that faces remain parallel to the original faces of the nucleus, and which concur with the faces produced by decrement, to modify the form of the crystal. Suppose, for example, that the law which produces an octahedron from a cube (described above) should combine with that from which results the dodecahedron with pentagonal faces. (Fig. 12.) The first of these laws would produce eight faces, which would have, for centres, the eight angles of the cubic nucleus. It is easy to see that each of these faces, that, for example, whose centre coincides with the solid angle O, (Fig. 12.) will be parallel to the equilateral triangle, whose sides pass through the points p, s, t. In like manner, the face whose centre coincides with the point O′, will be parallel to the equilateral triangle, whose sides pass through the points s, n, p'. But the second law produces faces situated as the pentagons, cut by the sides of the triangles $p's t$, $s n p'$. Now the section of these triangles upon the pentagon $t\,O\,s\,O'\,n$, reduces the pentagon to an isosceles triangle, which has the line tn for the base, and the two other sides of which pass through the points t, s, and n, s. The same thing takes place with the other pentagons. Hence it follows that the secondary crystal produced will be an icosahedron, bounded by eight equilateral triangles, and 12 isosceles triangles.

Plate CCXXII. Fig 12.

Fig. 7. represents this icosahedron, in which the letters correspond with those of Fig. 12. Plate CCXXII. and shew to the eye the relation between the two solids. But this icosahedron has dimensions much greater than those of the icosahedron which would be obtained by making sections of the eight solid angles of the dodecahedron (Fig. 12.), which are identified with those of the nu-

Plate CCXXIII. Fig. 7.

Theory.

cleus. This increase of size was necessary to preserve the size of the nucleus. This will be better understood by the following illustration.

If we wished to obtain the nucleus from the icosahedron of Fig. 7, it is evident that the fractures must be made in directions parallel to the edges *r s*, *t n*, *p q* (Figs. 12. and 7.), so that they should be equally inclined upon the faces of which they form the junction. These planes would pass at the same time through the equilateral triangles *p s t*, *s n p'*, &c. and we would obtain the nucleus when they all met at the centres of the equilateral triangles.

Plate CCXXII. Fig. 12. Plate CCXXIII. Fig. 7.

It follows from this, that the nucleus, the edges of which OI, OE, &c. (Fig. 12.) were uncovered upon the surface of the dodecahedron, is entirely enveloped in the icosahedron (Fig. 7.), excepting its solid angles, which are only points, and which constitute the centres of the equilateral triangles. This being understood, in order to form an accurate idea of the structure of the icosahedron, we must conceive that the plates applied to the nucleus for a certain period undergo decrements only at the angles, as if the secondary solid were to be a regular octahedron. Beyond this term (the decrement on the angles continuing always) a new decrement takes place and combines with the preceding; and this new decrement being relative to the dodecahedron, produces the twelve isosceles triangles. In this manner we see how the nucleus is entirely inclosed in the dodecahedron, excepting the solid angles. The first plates of superposition, which only underwent a decrement on the angles, continued to envelope the nucleus by those portions of their edges which underwent no decrements. It is sometimes necessary to suppose, in this manner, different epochas to the different decrements, which concur to produce a compound secondary form when we wish to give a particular account of the mechanism of the structure.

Plate CCXXIII. Fig. 7. Plate CCXXII. Fig. 12.

From this statement it follows, that the distance between the centres of the equilateral triangles *p t s*, *q t s'* (Fig. 7.), ought to be equal to the corresponding edge OI of the nucleus (Fig. 12.), as it evidently is to the eye, as any one may satisfy himself by inspecting the two Figures.

The icosahedron just described, occurs among the secondary crystals of pyrites. Naturalists at first were disposed to consider this as the regular geometrical icosahedron. But it has been demonstrated by Hauy, that the regular icosahedron does not exist among crystals, and cannot be produced by any law of decrement whatever. The same remark applies to the dodecahedron of mathematicians, a solid bounded by twelve regular and equal pentagons. No such crystal exists, nor can be produced by any law of decrement whatever. Of the five regular solids of mathematicians, the cube, the tetrahedron, the octahedron, the dodecahedron, and the icosahedron, the first three occur in the mineral kingdom, but not the last two.

Plate CCXXII. Fig. 1. Plate CCXXII. Fig. 5.

It will be worth while to give another example of a compound secondary form; and we shall take for that purpose the regular six-sided prism of calcareous spar (Fig. 1.) From the account formerly given of the manner of dissecting this prism, it is easy to conceive that its rhomboidal nucleus AA' (Fig. 5.) has its solid lateral angles E, O, I, K, G, H situated in the middle of the faces of the prisms; from which it follows, that these angles are the points from which the decrements set out that produce these faces.

These decrements act at once upon the three plain angles EOI, EOA', IOA'; but we may satisfy ourselves with considering the decrement relative to one of these angles, supposing the face which results from it extends itself upon the two adjacent rhombs belonging to the same angle. Let us agree, therefore, to restrict the whole to the six angles EOI, EHG, IKG, HGK, OIK, HGO, the three first of which are turned towards the summit A, and the three last to the summit A'. If we suppose a decrement by two ranges of rhomboidal molecules on these different angles, six faces will be produced parallel to the axis, as has been already observed.

Plate CCXXII. Figs. 4, 5.

The plates of superposition, at the same time that they undergo a decrement towards their inferior angles, will extend by their superior parts so as to remain always contiguous to the axis, the length of which will progressively augment. The faces produced by the decrement will gradually increase, and when they touch each other we shall have the solid AA' (Fig. 4.), where each of the faces, as *o* O *o*, is marked by the same letter as the angle O (Fig. 5.), to which it belongs, and which is now situated in the middle of the triangle *o* O *o*, because it constitutes the common point from which the three decrements set out.

In proportion as new plates are applied after this to the preceding ones, the points *o*, *o* rise up, while the point O sinks down, so that at a certain period we shall have the solid represented by Fig. 3, where the faces produced by the decrements are become pentagons, such as *o o i* O *e*.

Plate CCXXII. Fig. 1.

Things being in this state, let us suppose a second decrement to concur with the first, and to take place by a single range upon the superior angle EAI (Fig. 5.), and its opposite angle HA'K, always with this condition, that the face produced by it on both ends of the figure is continued upon the two rhombs adjacent to that to which the angles EAI, HA'K belong. The effect of this decrement will be, to produce two faces perpendicular to the axis; and when it has reached the point at which these faces cut the six faces parallel to the axis, produced by the first decrement, the secondary solid will be completed, and will be a regular six-sided prism (Fig. 1.)

Fig. 2. Fig. 5.

We have already said that this result is general, whatever be the measure of the angles of the primitive rhomboid. We now see why, in the mechanical division of the prism, the cut *p p o o* (Fig. 2.) has its sides *p p*, *o o* parallel to each other, and to the horizontal diagonal EI (Fig. 5.); since the two decrements taking place, the one upon the angles EOI, the other upon the angle EAI, the plates of superposition ought to have their edges turned towards this same diagonal.

In the case which we have been considering, and which is the most usual, the axis of the secondary crystal is longer than that of the nucleus; so that this nucleus having its lateral angles contiguous to the faces of the prism, its summits are inclosed within the prism, at a certain distance above the centre of the bases. If we were to suppose that the two decrements began at the same time, in that case the axis of the prism would be equal to that of the nucleus, and the lateral angles and summits of the nucleus would be tangents, the one to the faces of the prism, the other to its bases. If the decrements on the superior angles of the nucleus were anterior to the other decrements, which is the opposite of the first case, the summits of the nucleus would then be contiguous to the bases of the prism, while its lateral angles would be wholly within the prism, between

Theory.

the axis and the prismatic faces. This is the case with certain crystals in which the prism is very short, and resembles an hexagonal plate.

From the preceding account, we see upon what all the different metamorphoses depend, under which the primitive form of crystals presents itself in the secondary forms, whether simple or compound. Sometimes decrements take place at once upon all the edges, as when the rhomboidal dodecahedron is formed from the cube; or upon all the angles, as when the regular octahedron is formed from the cube. Sometimes they take place only on certain edges or certain angles. Sometimes they are uniform, so that only one law exists of decrements by one, two, three, &c. ranges, which acts upon different edges or angles. Sometimes the law varies from one edge to another, or from one angle to another; and this happens chiefly when the nucleus has not a symmetrical form, as when it is a parallelopiped, whose faces differ in the respective inclinations of their faces, or in the measure of their angles. In certain cases, the decrements on the edges concur with those on the angles to produce the same crystalline form. It happens likewise, sometimes, that the same edge, or the same angle, undergoes different laws of decrement, which succeed each other. And, finally, there are a great many cases where the secondary crystal preserves faces parallel to those of the primitive form, and which combine with the faces produced by decrement to modify the figure of the crystal.

If in the midst of such a diversity of laws, sometimes acting solitary, and sometimes in combination, upon the same primitive form, the number of ranges subtracted were likewise very variable; if, for example, there were decrements by 20, 30, 40, or a greater number of ranges of molecules, as is very possible in conception; the multitude of forms which might exist in each mineral species would be sufficient to confound the imagination; and the study of crystallography would present an immense labyrinth, from which, even when assisted by the theory, it would be difficult to extricate one's self. But the force which produces the subtractions appears to have a very limited action. Generally these subtractions take place only by one or two rows of molecules. None have hitherto been observed beyond six rows. But such is the fecundity united with this simplicity, that, supposing we confine ourselves to decrements by one, two, three, and four rows, and exclude those that are mixed or intermediate, we find that the rhomboid is susceptible of 8,388,604 varieties of crystallization. Doubtless many of these varieties do not occur in nature. But there is reason to expect, that discoveries in this field of enquiry will be made in great numbers for a long time to come. Accordingly, many new varieties of crystals have been described since Hauy published his Treatise on the subject; indeed they occur in such abundance, that we can hardly examine a group of crystals without observing varieties that have not yet been described. We are greatly within bounds when we say, that, from the observations already made, it would be possible to at ast double the number of crystals described by Hauy; nor have we reason to believe that the field is in the least degree exhausted. Indeed the number of persons who have turned their attention to crystallography, is much too small to be consistent with a careful survey of the crystals already collected, and deposited in different cabinets.

To have a still more correct idea of the power of crystallization, we must join to that facility which it has of producing so many different forms in setting out from the same form, that of the power which it has of arriving at the same form by different structures. The rhomboidal dodecahedron, for example, which we have seen formed by a combination of cubic molecules, exists likewise in the garnet composed of tetrahedral molecules, with isosceles triangular faces. It occurs also in fluate of lime, where it is composed of regular tetrahedrons. It is even possible for similar molecules, subjected to different laws, to present the same result. Thus the regular six-sided prism, which in calcareous spar exists usually in consequence of a decrement on the inferior angle, is produced sometimes in consequence of a decrement upon the edges adjacent to that angle. Even the primitive form may be produced by a law of decrement. In those species, particularly where the primitive form has a certain symmetry, as when it is a rhomboid, analogies and properties present themselves on all sides. It seems as if geometry could not touch a single term of the immense series of possibles, without leaving the mark of some interesting truth.

The preceding details, we presume, are sufficient to give a general and pretty accurate notion of the formation of those secondary crystals, whose molecules are parallelopipeds. But we have observed above, that there are many species in which the molecules are tetrahedrons or triangular prisms. It will be requisite to make a few observations on the method of proceeding in such cases.

Of Secondary Forms, when the Molecules differ from Parallelopipeds.

Of secondary forms.

It is a character common to all the primitive forms, to be divisible by fractures parallel to their different faces. In the parallelopiped, when it is not joined by some other in a different direction, such a division leads us obviously to the form of a molecule, similar to that of the primitive crystal. In the regular six-sided prism, it gives us for a molecule a triangular equilateral prism. In the octahedron, it appears to produce molecules of two different forms, some by tetrahedrons and octahedrons; the same thing happens with respect to the tetrahedron. Various ideas have been suggested by philosophers to get over the difficulty in this case. Dr Wollaston has got rid of it by supposing the molecules to be spherical, and to produce the tetrahedrons and octahedrons, by combining in fours and sixes. Hauy conceives that the tetrahedron is the integrant molecule, and that the octahedrons are nothing else than empty spaces between the molecules, produced by these molecules uniting by their angles. The subject does not admit of decision; but as it is of no consequence to the theory of crystallography what opinion we adopt, there is no occasion to enter upon the discussion of the subject here. The rhomboidal dodecahedron, when divided in this manner, gives tetrahedrons of isosceles triangular faces, equal and similar to each other.

With respect to the dodecahedron with isosceles triangular faces, we cannot extract its integrant molecules without dividing it in directions different from those which are parallel to the faces. The cutting plains must pass through the axis, and through the edges contiguous to angles of the summit. The molecules obtained are irregular tetrahedrons. The other primitive forms sometimes admit of division in directions

Theory.

not parallel to the faces. This is the case with the rhomboid, which constitutes the primitive form of the tourmaline. It may be divided by planes passing through the axis and the oblique diagonals. The result is the production of tetrahedral molecules, such as are represented in Fig. 9.

Plate CCXXII. Fig. 9.

Thus, besides parallelopipeds, there are two other shapes which the integrant molecules assume; namely, the tetrahedron, and the triangular prism. Now, it deserves attention, and it is a point of considerable consequence in the theory of crystals, that the tetrahedral and prismatic molecules are always arranged in such a manner in the interior of primitive and secondary crystals, that, taking them in groups of 2, 4, 6, or 8, they compose parallelopipeds; so that the ranges subtracted by the effect of decrement, are nothing else than these parallelopipeds.

In order to conceive the better how this may be, let us suppose for an instant that the molecules of calcareous spar are divisible into tetrahedrons, as is the case with the rhomboid, which constitutes the primitive form of the tourmaline. This supposition will change nothing in the explanation of the different forms of which calcareous spar is susceptible; that is to say, that in determining the forms of this mineral, aided by the theory, we may always satisfy ourselves with considering decrements by one or more ranges of rhomboidal molecules.

What is only a hypothesis with respect to calcareous spar, is a reality with regard to the tourmaline. But although the rhomboids, to which we arrive by mechanical division in this species, are themselves divisible into tetrahedrons, still the decrements which produce the secondary forms take place by the subtraction of rhomboids similar to the primitive form; so that we may suppose, in the calculations relative to the determination of these forms, that the tetrahedrons which constitute the true molecules are united together in an invariable manner, in each rhomboid.

Let us take another example from those crystals whose primitive form is a regular six-sided prism. Let AD (Fig. 8.) be the base of such a prism, divided into small triangles, which constitute the bases of the integrant molecules. It is evident, that any two neighbouring triangles whatever, such as A *p i*, AO *i*, compose a rhomb, and of course the two prisms to which they belong form by their union a prism with a rhomboidal base, which is a species of parallelopiped. If we conceive that the two triangular prisms, which constitute elements of the parallelopipeds, are invariably united together, it is obvious that we may consider the six-sided prism as composed of rhomboids instead of triangular prisms. Now, if we conceive a series of plates piled upon the hexagon ABCDFG (Fig. 8.), which undergo, for example, upon their different edges, a subtraction of one row of parallelopipeds similar to those that we are supposing here, these edges will successively correspond with the lines of the hexagon *i l m n r h*, *k u x y g e*, &c.; from which we see, that the quantity that each plate passes the other is a sum of parallelopipeds or prisms with rhomboidal bases; and it is easy to judge, that the result of the decrement, supposing it to reach its limit, will be a right hexangular pyramid, which will have for its base the hexagon ABCDFG.

Plate CCXXII. Fig. 8.

All the other primitive forms different from the parallelopiped, give analogous results. We might even substitute for each of these forms a nucleus similar to the little parallelopipeds, which are formed by the union of the tetrahedrons or triangular prisms, and we would succeed equally in explaining the secondary forms by laws of decrement applied to that nucleus, which would be obtained likewise by mechanical division.

Theory.

The Abbé Hauy, to whom we are indebted for the whole theory of crystals, calls these parallelopipeds, composed of tetrahedrons or triangular prisms, *subtractive molecules*. They are always substituted in place of the tetrahedrons or triangular prisms, in considering the decrements which produce the secondary forms in these cases. Thus, as far as the theory of crystals is concerned, we have nothing to do with the integrant molecules, but may conceive all crystals composed of a congeries of parallelopipeds.

Though we have extended this Chapter to a considerable length, there is still another particular which requires explanation, before we proceed to the mathematical theory. The Abbé Hauy has invented particular symbols to denote the particular laws of decrement which produce the secondary forms. As these symbols occur constantly in his writings, and as they are useful, by greatly shortening the account of the formation of secondary crystals, it is proper they should be understood. We shall endeavour, therefore, to explain them in this place.

Hauy's symbols. Plate CCXXIII. Fig. 8.

Let Fig. 8. represent an oblique parallelopiped, the faces of which have angles with different measures, and let it be the primitive form of some mineral; as, for example, of felspar.

The vowels are adopted to represent the solid angles. The four first, A, E, I, O, are placed at the four angles of the superior base following the order of the alphabet, and that of ordinary writing, namely, beginning at the top, and going from left to right.

The consonants are chosen to denote the edges. The six first, B, C, D, F, G, H, are placed on the middle of the edges of the superior base, and upon the two longitudinal edges of the lateral faces, which occur first in going from left to right. These consonants are likewise arranged in the alphabetical order, and according to the usual mode of writing.

The letters P, M, T, which are the initials of the syllables of which the word *primitive* is composed, are placed each in the middle of the superior base, and of the two lateral faces exhibited to view.

Each of the four solid angles, or of the six edges marked by letters, is susceptible in the present case, on account of the irregular form of the parallelopiped, of undergoing particular laws of decrement. Hence the reason why they are marked each with a different letter. But as the laws of decrement act with the greatest symmetry possible, every thing which takes place with respect to the angles and edges marked with letters, takes place also with respect to the opposite angles and edges which are not marked, or are not visible. It was only necessary to mark the number of solid angles or edges which undergo distinct decrements, because these decrements include likewise implicitly all those which take place upon analogous angles or edges.

In some cases, however, it is necessary to indicate these last angles or edges. In such cases, the small letters, having the same names as the capitals, are employed for the purpose. The angles analogous to A, E, I, O, are denoted by *a, e, i, o*; and the edges analogous to B, C, D, F, G, H, are denoted by *b, c, d, f, g, h*. But it is very seldom necessary to mark these small letters on the Figure; it is sufficient to introduce them

Theory.

into the symbol of the crystal, because it is easy to conceive the place which every one ought to occupy in the Figure.

To indicate the effects of decrements by one, two, three, four, or more ranges in breadth, the figures 1, 2, 3, 4, &c. are employed in the way to be immediately explained; and, to indicate the effects of decrements by 2, 3, &c. ranges in height, the fractions $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, &c. are employed.

The three letters P, M, T, serve to distinguish either the form of the nucleus, without any modification, when they alone constitute the symbol of the crystal, or the faces parallel to those of the nucleus, in the case where the decrements do not reach their limit; and then these letters are combined in the symbol of the crystal with those which relate to the angles or edges that have undergone decrements.

Let us suppose at first, for the greater simplicity, that one of the solid angles, such as O, is intercepted by a single additional face. The decrement which produces this face may take place either on the base P, or on the face T, which is on the right of the observer; or on the face M, which is on the left. In the first case, the figure marking the decrement is placed above the letter O; in the second case, the figure is placed like an ordinary exponent; in the third case, it is placed on the left side, and somewhat above the letter.

Thus, $\overset{2}{O}$ denotes the effect of a decrement by two ranges in breadth, parallel to the diagonal of the base P, which passes through the angle E. O^3 indicates the effect of a decrement by three ranges in breadth, parallel to the diagonal of the face T, which passes through the angle I. ^4O indicates the effect of a decrement by four ranges in breadth, parallel to the diagonal of the face M that passes through the angle E.

When the decrement relates to some one of the three other solid angles I, A, E, the observer is conceived to move round the crystal till he is opposite to that angle, as he is naturally opposite to the angle O in the case which we have been describing; or, which comes to the same thing, he is conceived to turn round the crystal till the solid angle that he is considering be exactly opposite to him, and it is relative to that position that a decrement is said to take place towards the right or towards the left.

Plate CCXXIII. Fig. 8, 9.

For example, if we are speaking of the solid angle A, the sign A^2 will represent the effect of a decrement by two ranges on the surface AE *s r* (Fig. 9.), or upon that which is opposite to T (Fig. 8.); and ^3A will represent the effect of a decrement by three ranges upon the face AI *u r* (Fig. 9.), or upon that which is opposite to M (Fig. 8.)

As to the decrements on the edges, those which take place towards the boundary BCFD of the base, are expressed by a number placed above or below the letter, according as their effect takes place in going up or going down, supposing them to set out from the edge to which they are referred; while those which take place on the longitudinal edges G, H, are indicated by an exponent placed on the right or the left of the letter, according as they take place in one direction or the other. Thus $\overset{2}{D}$ expresses a decrement by two ranges proceeding from D towards C; $\overset{3}{C}$ a decrement by three ranges going from C towards D; $\underset{2}{D}$ a decrement by two ranges, descending upon the face M; ^3H a decrement by three ranges, proceeding from H towards G; ^4G a decrement by four ranges, proceeding from G towards the edge opposite to H, &c.

Theory.

Plate CCXXIII. Fig 8, 9.

When it is necessary to denote by a small letter, such as *d*, a decrement upon the edge *u r* (Fig. 9.), opposite to the edge denoted by the capital letter D (Fig 8.), we must suppose the crystal turned upside down. Hence $\overset{2}{d}$ will express a decrement by two ranges upon the base *p*, just as $\overset{2}{D}$ expresses a similar decrement on the base P. For the same reason, $\overset{3}{c}$ will express a decrement by three ranges, proceeding from *s p* towards EO (Fig. 9.)

If the same solid angle, or the same edge, undergo several successive decrements on the same side, or different decrements which take place on different sides, in that case, the letter pointing out the angle or edge is repeated as often as the decrements, varying the figure each time, to make it correspond with the particular decrements pointed out. Thus $\overset{2}{D}$ $\underset{3}{D}$ will denote two decrements upon the edge D, one of two ranges upon the base P, another of three ranges upon the face M. ^2H ^4H will denote two decrements, the one by two ranges, the other by four, on the left of the edge H.

Mixed decrements are marked according to the same principles, employing the fractions $\frac{2}{3}$, $\frac{3}{4}$, &c. which represent them; the numerator referring to the decrements in breadth, and the denominator to decrements in height.

Fig. 8. 10.

The method of describing the intermediate decrements still remains to be explained. This will be best done by an example. Let AEOI (Fig. 10.) be the same face as in Fig. 8. Let us suppose a decrement by one range of double molecules, according to lines parallel to *x y*, so that O *y* measures the double length of a molecule, and O *x* lines equal to that of a single molecule. This kind of decrement is written in this manner, ($\overset{1}{O}$ D^1 F^2). The parenthesis lets us know, in the first place, that the decrement is intermediate; $\overset{1}{O}$ indicates that it takes place by one range upon the angle marked by that lettter, and that it belongs to the base AEOI (Fig. 8.) D^1 F^2 indicate that there is one length of a molecule taken away along the edge D, and two lengths along the edge F.

It is useful to have a language to denote these symbols, so that they may be easily written down when dictated by another person. On that account, we shall mention here the mode followed by Hauy for that purpose. The symbols O^2, ^3O, are thus read: O *two on the right*, O *three on the left*, $\overset{2}{O}$, $\underset{4}{O}$ thus, O *under two*, O *above four*. Finally, the symbol ($\overset{1}{O}$ D^1 F^2) thus, *in a parenthesis*, O *under one*, D *one*, F *two*.

We must now notice the order in which these letters must be placed, in order to denote a secondary crystal. If the alphabetical order were adopted, there would result a sort of confusion in the picture which the formula presents. It is more natural to conform to the order which would direct an observer in the description of the crystal; that is to say, to begin with the prism or the middle part, and to indicate its different faces as they present themselves successively to the eye, then to pass to the faces of the summit or the pyramid.

Fig. 8. 11.

Suppose, now, that Fig. 11. represents the variety of felspar called *bibinaire* by Hauy, the primitive form of which is seen in Fig. 8. In this variety, the face *l* (Fig. 11.) results from a decrement by two ranges on the edge G, (Fig. 8.) going towards H. The face M (Fig. 11.) corresponds with that which is marked with the same letter in Fig. 8. and which is only concealed

Theory.

Plate CCXXIII. Fig. 8. 11.

in part by the effect of the decrement. The face T (Fig. 11.) is parallel to T (Fig. 8.) The pentagon x (Fig. 11.) comes from a decrement by two ranges on the angle I (Fig. 8.) parallel to the diagonal AO. As this decrement does not reach its limit, the summit exhibits a second pentagon P (Fig. 11.) parallel to the base P (Fig. 8.) All this description may be exhibited in symbolic language as follows: $G^2\,M\,T\,\overset{2}{I}\,P$.

In order to prevent beginners from finding any thing ambiguous in this symbolical mode of writing, especially in complicated cases, Hauy is in the habit of placing under the different letters which compose the symbol, those which correspond to them in the figure. If we adopt this mode, which is a considerable improvement, the symbol denoting *bibinaire* felspar will be as follows:

$$\begin{array}{ccccc} G^2 & M & T & \overset{2}{I} & P. \\ l & M & T & x & P. \end{array}$$

These letters thus written below, enable us to compare the symbol with the figure, and thus to decypher the meaning with facility, how complicated soever it should be. But some more observations will be necessary, in order to understand fully the way in which Hauy employs these symbols.

Let us now then turn our attention to parallelopipeds of a more regular form than that which constitutes the primitive crystal of felspar. But let us suppose them at first not to be rhomboids. They are nothing else than what is represented in Fig. 8. but the form has varied so as to render them symmetrical. In consequence of this alteration, certain angles and edges which differed from each other in the first parallelopiped, have become equal in this. Hence, every thing that takes place on one of them is repeated on the other. They ought therefore to be denoted by the same letter. Thus, in algebra, certain general solutions are simplified in particular cases, when a quantity at first supposed to be different from another becomes equal to it.

Let us suppose, for example, that the primitive form is a rectangular prism, having oblique angled parallelograms for its bases, one side of which is longer than the other. In that case, we have O=A (Fig. 8.), I=E, &c. In such a case, the first letter of the alphabet will be substituted for the other, as is done in Fig. 12.

If we pass through the different kinds of parallelopipeds, we shall find them acquire different degrees of simplicity, which occasions new equalities in the angles and edges, and of course new substitutions of letters. We shall have successively,

The oblique prism with rhomboidal bases represented in Fig. 13.

The rectangular prism, with rectangular bases, represented in Fig. 14.

The rectangular prism, with rhomboidal bases, represented in Fig. 15.

The rectangular prism, with square bases, represented in Fig. 16.

The cube represented in Fig. 17. Here only the superior base is marked with letters, because what takes place with respect to it may be applied indifferently to any of the other faces.

The same mode is followed in writing the symbols for these different forms, only the letters that have the same name and the same figures, are not repeated.

Fig. 18. An example will render the method evident. Fig. 18. represents the most common variety of the *cymophane*, the nucleus of which is a rectangular parallelopiped, such as is represented in Fig. 14. The symbol of the secondary crystal will be

Theory.

$$\begin{array}{ccccccc} M & T & {}^2G & G^2 & \overset{1}{B} & A^{\frac{3}{2}} & {}^{\frac{3}{2}}A. \\ M & T & & s & i & o & \end{array}$$

Hauy has called this variety annular cymophane.

To understand the preceding expression better, let us mark each angle and edge with a particular letter, as if the parallelopiped were oblique angled. See Fig. 19. In that case the symbol would become $MT\,{}^2G\,H^2\,\overset{1}{B}\,\overset{1}{F}\,E^{\frac{3}{2}}\,{}^{\frac{3}{2}}O$. But if we compare Fig. 19. with Fig. 14. we see that H=G, F=B, O=A, &c. Hence, if we substitute, instead of the first letters, their values, we get $MT\,{}^2G\,G^2\,\overset{1}{B}\,\overset{1}{B}\,A^{\frac{3}{2}}\,{}^{\frac{3}{2}}A$, which becomes the same with the one given above, when the useless repetition of $\overset{1}{B}$ is suppressed.

Plate CCXXIII. Fig. 19.

From the preceding statement, it is evident that we must take care not to confound, for example, ${}^2G\,G^2$ with $G^2\,{}^2G$. The first symbol indicates the decrements which take place on the face T (Fig. 14.) and on the face opposite to it, going from the edges G towards those that correspond with them behind the parallelopiped. The second indicates the decrements which take place upon the face M, and which meet each other in the middle of that face. If these two decrements took place simultaneously, their symbol would be ${}^2G^2$.

In the preceding symbols, each letter, such as ${}^2G$ or G^2 can only be applied to a single edge, situated to the right or the left, as that letter itself. But ${}^2G^2$ applies indifferently to the one edge or the other. Hence, it is needless to repeat that letter.

Let us take the Figure 20. as another example.* If we suppose Fig. 15. to represent its primitive form, we will have for the symbol of the variety of crystal here represented, Fig. 20.

$$\begin{array}{ccccccc} {}^3G^3 & M & \overset{2}{B} & \overset{3}{B} & \overset{1}{E} & \overset{2}{E} & P \\ o & M & r & s & z & u & P \end{array}$$

In this symbol ${}^3G^3$ indicates two distinct faces formed on each side of each edge G. But it is not necessary to place two letters under that symbol, because all the faces situated in the same manner being distinguished by the same letter in the figure, it is sufficient to point out that the symbol ${}^3G^3$ applies to the faces marked with the letter *o*, and this requires only to write the letter *o* once under the symbol.

From the same principles, it follows, that the rhomboidal dodecahedron derived from the cube, (Fig. 17.) is expressed by the symbol $\overset{1}{B}\,\underset{1}{B}$. The octahedron derived from the cube is expressed thus, $\overset{1}{A}\,{}^1A^1$.

The rhomboid, supposing it placed in the most natural aspect, that is to say, so that the two solid angles composed of three equal plane angles, are in the same vertical line, has properly speaking no base, but merely summits, which are the extremities of its axis. Its angles and edges are marked as in Fig. 21. The letter *e* denotes that the angle marked by it is similar to that which is marked with a capital E. So that if all the lateral angles were indicated by letters, the three nearest the superior summit would have the letter E, and the three nearest the inferior summit the letter *e*.

As the rhomboid has its six faces equal and similar, it is only necessary to consider the decrements relative

* This Figure represents a variety of the topaz; of course, our supposition respecting the primitive crystal is not accurate. But that does not injure the illustration.

Theory.

to one of these faces; as, for example, the one which in the Figure is marked P, because all the others are mere repetitions of this. These observations suggest the following rules: 1. The decrements which set out from the superior angle A, or the superior edge B, will have the figure indicating the number of ranges placed below A and B. 2. Those which set out from the lateral angles E will have their figures situated at the side and towards the top of the same letter. 3. With respect to those which set out from the inferior angle *e*, or from the inferior edge D, the figure will be placed above the letter *e* or D.

PLATE CCXXIII. Fig. 22.

Suppose, for example, that Fig. 22. represents the variety of calcareous spar, called *analogic* by Hauy, its symbol will be $\overset{2}{e}\ \overset{2}{\mathrm{D}}\ \underset{1}{\mathrm{B}}$.

$$\begin{matrix} c & r & g \end{matrix}$$

What has been said of the rhomboid is easily applied to the other primitive forms. But probably some illustrations will be considered as necessary to make the symbols applied to them the more readily understood. On that account we shall take a short review of each of them.

Figs. 23, 24, 25.

Fig. 23. represents the octahedron with scalene triangles, Fig. 24. the octahedron with isosceles triangles, and Fig. 25. the regular octahedron.

In placing the figures which accompany the letters in the symbols, the same rule is followed that was described with respect to the rhomboid. Thus, in Fig. 24. the figure is placed below the letter to represent decrements setting out from the angle A or the edge B; it is placed above for those which set out from the edge D, and at the side for those which set out from the angle E. If we want to denote the result of a decrement by one range upon all the angles of the regular octahedron (Fig. 25.) we have only to write $\overset{1}{\mathrm{A}}\,{}^{1}\mathrm{A}^{1}$. To indicate the result of a decrement by one range on all the edges, we write $\underset{1}{\mathrm{B}}\ \overset{1}{\mathrm{B}}$. The first of these decrements produces a cube, the second a rhomboidal dodecahedron.

In some species, as in the nitrate of potash, the primitive octahedron, the surface of which is composed of eight isosceles triangles, similar 4 and 4 to each other, ought to have the position represented in Fig. 26. that the secondary crystals may have the most natural attitude, that is to say, that the edges which join the two pyramids which compose the octahedron, ought to be two of them in a vertical direction, as F, and two in a horizontal, as B. By comparing Fig. 26. with Fig. 27. in which the letters are placed as if all the angles and edges had different functions, it will be easy to conceive the distribution adopted in Fig. 26. and brought to the symmetry of the true primitive form. For, in the present case, we have E=A, D=C, G=F.

Figs. 26, 27.

The figure denoting the number of ranges, will be placed under the letter, to denote decrements proceeding from B. It will be placed at one side, or below, to denote those proceeding from A; according as their effect respects the triangle AIA, or the triangle AIF. It will be placed above or below, for those which proceed from C, according as their effect is produced on the first or the second of these triangles. It will be placed at one side for the decrements which proceed from F. Finally, it will be placed above, below, or on either side, for the decrements that proceed from I, according as their effect takes place towards B or towards F.

The tetrahedron being always regular, when it becomes the primitive form, it will be expressed as in Fig. 28. To indicate, for example, a decrement by three ranges on all the edges, we would write $\underset{3}{\mathrm{B}}\ \overset{3}{\mathrm{B}}$; and to indicate a decrement by two ranges upon all the angles, we would write $\underset{2}{\mathrm{A}}\,{}^{2}\mathrm{A}^{2}$, as in the case of the regular octahedron.

Theory.

PLATE CCXXIII. Fig. 28.

A simple inspection of Fig. 29. is sufficient to make us understand the symbols in the case of regular six-sided prisms. The figures are written precisely in the manner already decribed for the four-sided prism; to which, therefore, we refer the reader. But it happens sometimes that three of the solid angles taken alternately are replaced by faces, while the intermediate angles remain untouched. In that case the prism is distinguished as in Fig. 30.

Fig. 29.

Fig. 30.

In the rhomboidal dodecahedron (Fig. 31.) each solid angle composed of three planes may be assimilated to a summit of the obtuse rhomboid. Hence, it is only necessary to give letters to one face, as may be seen in the Figure.

Fig. 31.

Hitherto there has been no occasion to use any symbols for the dodecahedron with triangular faces, because it is more natural to substitute in place of it the rhomboid from which it is derived, and which gives simpler laws of decrement.

We have still to explain the method of representing a peculiar case, which sometimes occurs in some crystals, where the parts opposite to those which undergo certain decrements remain untouched, or are modified by different laws. This case belongs chiefly to the tourmaline, and it is easy to indicate its peculiarity by means of zeros.

For example, in the variety of tourmaline represented in Fig. 33. the primitive form of which is represented in Fig. 32.; the prism, which is nine-sided, has six of its faces, namely, *s*, *s* (Fig. 33.) produced by the subtraction of one range upon the edges D, D (Fig. 32.) and the three others, such as *l*, by the subtraction of two ranges on the three angles *e* (Fig. 32.) only. Farther, the inferior summit has only three faces parallel to those of the nucleus; while, on the superior summit, the three edges B are replaced each by a face *n*, *n* (Fig. 33.) in consequence of a decrement which has not reached its limit. This crystal is represented by the following symbol: $\overset{1}{\mathrm{D}}\ \overset{2}{e}\ \overset{2.0}{\mathrm{E}}\ \mathrm{P}\ \underset{1}{\mathrm{B}}\ \underset{1.0}{b}$. The quantities

Figs 32, 33.

$$\begin{matrix} s & l & & \mathrm{P} & n \end{matrix}$$

${}^{2.0}\mathrm{E}$, $\underset{1.0}{b}$ indicate, the one that the angles E (Fig. 32.) opposite to *e* undergo no decrement; the other, that the edges parallel to B remain equally untouched.

If these edges underwent a different law, which produced, for example, an abstraction of two ranges, the symbol would become $\overset{1}{\mathrm{D}}\ \overset{2}{e}\ \overset{2\ 0}{\mathrm{E}}\ \mathrm{P}\ \underset{1}{\mathrm{B}}\ \underset{2}{b}$. From this, it is obvious, that it must be understood that the decrements represented by a capital letter accompanied by any figure, do not implicitly include the similar decrements represented by a small letter of the same name, or the opposite, that is to say, that $\overset{2}{\mathrm{B}}$ does not implicitly include $\underset{2}{b}$, or *vice versa*, except when the second letter does not enter into the symbol with a different figure, or does not bear the same figure accompanied by a zero. In the first case, each of the two letters indicates a decrement which is peculiar to the edge or angle in-

Theory.

dicated by it. In the second case, the zero indicates that the angle or edge to which it exclusively relates undergoes no decrement whatever. Thus, in the symbol $\overset{1}{D}\,\overset{2}{e}\,\overset{2.0}{E}\ P\ \underset{1}{B}\ \underset{2}{b}$, $\underset{1}{B}$ expresses a decrement by one range, which takes place only on the edges contiguous to the superior summit A (Fig. 32.); $\underset{2}{b}$ indicates a decrement by two ranges, which only takes place on the edges contiguous to the inferior summit. The quantities $\overset{2}{e}$ and $\overset{2.0}{E}$ ought likewise to be considered independent of each other. The first indicating a decrement of two ranges on the angles *e* only, and the second indicating that no decrement whatever takes place upon the angles E, opposite to the preceding.

The preceding observations have been given in considerable detail, in order to put our readers completely in possession of the method, and to enable them to make a figure of a secondary crystal, merely from the symbol representing the laws of its formation. But to enable any person to read these symbols, and to understand them, much briefer directions would have sufficed. We shall subjoin the following rules, which will be sufficient for that purpose, and which will serve as a kind of epitome of the preceding observations:

General rules for understanding the symbols.

1. Every vowel employed in the symbol of a crystal indicates a solid angle, marked with the same letter in the figure which represents the nucleus. Every consonant indicates the edge which has the same letter in the figure.

2. Each vowel and consonant is accompanied by a figure, the value and position of which indicates the law of decrement which the corresponding angle or edge undergoes. We must except the three consonants P, M, T; each of which, when it appears in the symbol of a crystal, indicates that the crystal has faces parallel to those faces which have the same letters on the figure of the nucleus.

3. Each letter contained in the symbol of a crystal, is understood, with the figure belonging to it, to apply to all the angles or edges which have the same function as it in the figure, and is marked with the same letter.

4. Every number joined to a letter indicates a decrement, setting out from the angle or the edge denoted by that letter. If the number is a whole number, it indicates how many ranges in breadth are subtracted, supposing each plate to have only the thickness of one molecule. If the number is a fraction, the numerator indicates the number of ranges subtracted in breadth, and the denominator the number of ranges subtracted in height.

5. According as the number is placed below or above the letter which it accompanies, it indicates that the decrement descends or ascends, setting out from the angle or edge marked by the letter. If it is placed towards the top, and either on the right or the left side of the letter, it indicates a decrement in a lateral direction, either to the right or to the left of the angle or edge marked by the letter.

6. When a letter is twice repeated, with the same number placed on two different sides, as $^{2}G\,G^{2}$ or $G^{2}\,^{2}G$, $^{2}A\,A^{2}$ or $A^{2}\,^{2}A$, the two edges, or the two angles which it marks, ought to be considered on the figure in the same relative positions; that is to say, for example, that in the symbol $^{2}G\,G^{2}$, the quantity ^{2}G indicates the effect of decrement on the edge G situated at the left, and the quantity G^{2} the effect of decrement upon the edge situated at the right.

7. When a letter has the same number both on the left and the right side, as $^{3}G^{3}$, it applies equally to all the edges G. The same thing holds with the letters which belong to the angles.

Goniometers.

8. The parenthesis, as for example ($\overset{3}{O}D^{1}\,F^{2}$), indicates an intermediate decrement. The letter $\overset{3}{O}$ indicates, in the first place, that the decrement takes place by three ranges on the angle O, and that its effect is ascending. $D^{1}\,F^{2}$ indicate, that for one molecule subtracted along the edge D, there are two molecules subtracted along the edge F.

9. Every small letter occurring in the symbol of a crystal, indicates the angle or the edge diametrically opposite to that which has the capital letter of the same name in the figure, where the small letter is omitted as superfluous. We must except the letter *e*, which is always employed in the rhomboid, and which indicates, according to the principle, the angle opposite to that which bears the letter E.

10. When a symbol contains two letters of the same name, the one large the other small, with different numbers attached to them, the two opposite edges or angles to which these letters belong, are conceived to undergo each exclusively the law of decrement indicated by the number attached to the letter.

11. Every letter, whether large or small, marked by a number having a zero following it, indicates that the decrement denoted by that number does not take place on the particular edge or angle denoted by the letter.

Goniometers for measuring the angles of crystals.

As the whole theory of crystallization depends upon the knowledge of the angles which the different faces of the crystal make with one another, it is necessary to be in possession of instruments for measuring these angles. Such instruments are known by the name of Goniometers. The goniometer first employed is exhibited in Fig. 34. The way in which it is used must be obvious without much description. It consists of a semicircle of brass, divided into degrees. At its centre *c* is fixed a pin, upon which slide the two arms AB and GF. The last of these GF, by means of a screw, may be fixed in any position, so that the distance between the end G and the centre, may correspond with the face of the crystal to be measured. The other arm AB is drawn up, till the distance between B and the centre corresponds as nearly as possible with the size of the other face of the crystal. It is then turned round, till the angle of the crystal to be measured corresponds exactly with the angle B*c*G; the arm AB then cuts the semicircle in the angle which corresponds with that of the crystal. There is a hinge upon the middle of the brass semicircle, which is not seen in the figure. By means of it, one-half of the semicircle may be thrown back, when the crystal to be examined happens to be so situated in a group, that the arms could not otherwise come at it.

PLATE CCXXIII. Fig. 34.

Romé de Lisle's and Hauy's goniometers.

This was the only goniometer used by Romé de Lisle, and Hauy, when he published his Treatise on Mineralogy, in 1801. It can scarcely be depended on nearer than two or three degrees; or when the faces of the crystals are large and very smooth, perhaps a very steady hand, accustomed to handle the instrument, may come within one degree. On that account, the surprizing accuracy of many of Hauy's measurements reflects the greatest credit both on his care and his sagacity. It is true, indeed, that all his measurements are ultimately fixed by the application of his mathematical theory. But the original data of that theory itself are derived from the goniometrical measurement of angles. We

Goniometers.

see, from the mistake into which he has fallen in the case of calcareous spar, that not even the most seducing and numerous mathematical analogies are to be relied on in all cases. For nothing can be more conclusive in appearance, than his reasons for fixing upon a particular angle for the inclination of the faces in this crystal, yet they have led him to an inaccurate conclusion. Hence it would not be at all surprizing, if the measures which he assigns for a very considerable number of his primitive forms, should turn out ultimately nothing more than approximations.

Dr Wollaston's goniometer.

It was an object of great importance, therefore, to get a goniometer capable of measuring with a greater degree of accuracy. Dr Wollaston, to whose mechanical inventions the philosophical world lies under such obligations, has contrived one upon optical principles, susceptible of as great a degree of accuracy as is thought requisite. The original instrument of Dr Wollaston only measures angles within five minutes of the truth; but we have seen the same instrument made so as to come within half a minute; and Malus, by converting it to a repeating circle, has made it susceptible of as much accuracy as the experimenter chuses. But the truth is, that in the greater number of crystals it is not possible to measure the angles with perfect accuracy, from some imperfection in the crystal itself. The faces are often rough, and do not reflect the light equally. The best crystals for measuring with Dr Wollaston's goniometer, are those which are very small. When they are very small, and transparent, with smooth faces, we may arrive at any degree of precision we think proper.

Plate CCXXIV. Fig. 1.

Fig. 1. represents Dr Wollaston's goniometer, as originally constructed. It consists of a brass circle, graduated on its edge, and mounted on a horizontal axle, supported by an upright pillar. This axle being perforated, admits the passage of a smaller axle through it, to which any crystal of a moderate size may be attached by a piece of wax, with its edge, or intersection of the surfaces, horizontal and parallel to the axis of motion. This position of the crystal is first adjusted, so that, by turning the smaller axle, each of the two surfaces, whose inclination is to be measured, will reflect the same light to the eye. The circle is then set to zero, or to 180°, by an index attached to the pillar that supports it. The small axle is then turned, till the further surface reflects the light of a candle (or the bar of a window) to the eye; and, lastly, the eye being kept steadily in the same place, the circle is turned by its larger axle till the second surface reflects the same light. This second surface is thus ascertained to be in the same position as the former surface had been. The angle through which the circle has moved, is, in fact, the supplement to the inclination of the surfaces; but as the graduations on its margin are numbered accordingly in an inverted order, the angle is correctly shewn by the index without need of computation. The best way of using the instrument, is to place the eye within about an inch of the face of the crystal, and to turn it by means of the small axle, till a bar of the window, or some other distant object, be brought exactly to correspond with the bottom of the window. You then turn the circle till the other face is in the same position. The index now points out the size of the angle measured.

In Fig. 1, *a b* is the principal circle of the goniometer, graduated on its edge; *c c* the axle of the circle; *d* a milled head, by which the circle is turned; *e e* the small axle for turning the crystal without moving the circle; *f* a milled head on the small axle; *g* a brass plate supported by the pillar, and graduated as a vernier to every five minutes; *h* the extremity of a small spring, by which the circle is stopped at 180°, without the trouble of reading off; *i i* and *k k* are two centres of motion, the one horizontal, the other vertical, for adjusting the position of the crystal; one turned by the handle *l*, the other by the milled head *m*.

The crystal being attached to a screw-head at the point *n* (in the centre of all the motions), with one of its surfaces as nearly parallel as may be to the milled head *m*, is next rendered truly parallel to the axis by turning the handle *l*, till the reflected image of a horizontal line is seen to be horizontal. By means of the milled head *f*, the second surface is then brought into the position of the first; and if the reflected image from this surface is found not to be horizontal, it is rendered so by turning the milled head *m*; and since this motion is parallel to the first surface, it does not derange the preceding adjustment. See *Phil. Trans.* 1809, Part II.

Dr Brewster's goniometer. Plate CCXXIV. Fig. 2.

Another goniometer, upon optical principles, has likewise been invented by Dr Brewster. Fig. 2. exhibits a view of this goniometer. AB is a circle about six inches in diameter, divided into 360°. It moves round OO as a centre, and is supported by two upright bars M, N, fixed with screws into the stand SS. To the ring OO, supported by these bars, is fixed the arm G, that carries the vernier scale E. This scale remains stationary, while a rotatory motion is communicated to the divided circle AB, by means of a pinion moved by the milled head Q, which works in the teeth cut upon the circumference of the circle AB. A rectangular piece of brass L is fixed by two screws to one of the radii R of the graduated circle, so that the slider *s s* may move upon it, and be placed at different distances from the centre of motion, by laying hold of the pin below *s*. A thin plate *b c*, forming part of the cock *t b c* C on the top of this slider, carries the crystal, and by means of its projecting extremity *b* this plate has a motion round the screw *c*, in a plane perpendicular to that of the divided circle. Below this is another plate, which is seen at *a*, and which may be raised and depressed round an axis, one end of which appears at *x*, by turning the screw *t*, which works in the plate below *a*. Below the plate *a*, and fixed to it by the screw C, is another piece of brass fastened to the top of the slider by the screw above C, and moveable, by means of the lever *t*, round that screw as a centre, in the same plane with the circle. When the handle *b* is employed to move the plate *b c*, it is pushed to or from the plane of the circle AB. When the lever *t* is used to give the whole cock *b c* C a rotatory motion about the screw C, it is moved in a plane parallel to that of the circle AB; but when *t* is used to raise or depress the plates *b c*, and *a*, it is turned round like a screw. By the combination of these motions, the common section of the surfaces of the crystals is brought into a position parallel to the axis of the instrument. This adjustment is effected by placing the graduated circle in such a position, that a vertical window bar, or any other straight line, is nearly in the plane of the circle. A motion of rotation is then given to the crystal by the lever *t*; and if the reflected image of the window bar forms one straight line with the object itself, when examined in each surface of the crystal, the adjustment is complete, or the plane of the graduated circle is parallel to a plane at right angles to the edge or common section of the surfaces of the crystal. The instrument is then placed in such a position, that the plane passing through the eye and the window bar is perpendicular

Mathematical Theory.

to the plane of the divided circle, or that the edge or common section of the surfaces of the crystal, points to the bar of the window, the index is set to the beginning of the scale by means of a stop at the 180th degree, and the image of the vertical window bar, or any rectilineal object formed by reflection from the first or right hand surface of the crystal, is brought to coincide with the direct image by the vertical motion of the cock. The whole graduated circle is then made to revolve by the toothed pinion, till the reflected image of the vertical bar again coincides with the direct image when examined in the other surface of the crystal. When this position is obtained, the index of the vernier will point out, on the divided arch, the angle of the crystal. In order that the instrument may be used merely when held in the hand, a vertical frame HK is attached to it by the arm DH, and the parallel silver wires stretched across it are used instead of the window bar. See the article GONIOMETERS; and Brewster's *Treatise on New Philosophical Instruments*, p. 89.

We have never had an opportunity of seeing any description of the repeating goniometer of Malus. But it is easy to see how the goniometer of Wollaston might be made a repeating circle. In most cases, however, the use of such an instrument implies a degree of accuracy which cannot be attained in the mensuration of the angles of crystals.

CHAP. II.

Mathematical Theory of the Structure of Crystals.

Mathematical theory.

IN the preceding Chapter we have given a popular view of the structure of crystals, which we conceive will be easily understood by any attentive reader, even though he should not be conversant with mathematics. If we were to confine ourselves to this popular view of the subject, however, this article would have little utility, because it would be out of the power of readers to judge of the accuracy of the principles which have been laid down, or to understand how these principles were discovered. Far less would they be able to prosecute the subject themselves, to investigate the structure of new crystals, and to carry the theory of crystallization to a state of perfection. To bring this valuable branch of knowledge within their power, is the object of the present Chapter.

The whole mathematical theory of crystals belongs to the Abbé Hauy. For what has been done by others is, comparatively speaking, so trifling, that we may overlook it altogether. He has prosecuted the subject with indefatigable industry for more than 30 years. His first essays on it, appeared in the Memoirs of the French Academy. He afterwards published an Essay on the subject, in which he developed the mathematical theory. From that period to the year 1801, numerous papers of his appeared in the *Journal de Mines*, investigating the crystals belonging to different species of minerals. In the year 1801, his *Traité de Mineralogie* appeared. In this work he has inserted a complete view of the subject, so luminous and well arranged, that we shall have little more to do than to extract the essential parts of that treatise, unless there happen to be one or two cases in which subsequent improvements have been made. We ought to mention, that since the year 1801, numerous papers on the same subject have appeared in the *Journal de Mines;* and the *Annales de Museum d'Histoire Naturelle,* drawn up by the Abbé Hauy, and containing much new and valuable matter. Count Bournon has likewise published an important work on calcareous spar, in which he has given a theory of crystallization of his own, which has been animadverted on in a masterly manner by the Abbé Hauy, in one of the numbers of the *Annales de Museum d'Histoire Naturelle.* We are not aware that any thing has been published in Great Britain upon the mathematical theory of crystallization, though we are acquainted with several persons who have studied the subject. A valuable paper on the crystals of tinstone, by Mr Philips, has been presented to the Geological Society, and inserted in their transactions. The want of any English treatise on the subject, will oblige us to be more particular than would otherwise be proper for an article published in an Encyclopædia.

I. *Preliminary Notions.*

1. The object of the theory is to determine all the different forms which can be produced from the superposition of plates diminishing in size according to given laws, and in given directions, upon the different faces of a solid, the form of which is likewise given. Preliminary notions.

2. This solid, called the *nucleus* or *primitive form,* is always one of the six following: 1. The parallelopiped 2. The regular six-sided prism. 3. The rhomboidal dodecahedron. 4. The octahedron. 5. The regular tetrahedron. 6. The triangular dodecahedron, consisting of two six-sided pyramids, applied base to base.

3. By subdividing these primitive forms in the way described in the last Chapter, we obtain the shape of the integrant molecules. These are either, 1. Parallelopipeds. 2. Triangular prisms; or, 3. Tetrahedrons.

4. When the integrant molecules are tetrahedrons or triangular prisms, they are always so grouped together in the crystal, as to compose parallelopipeds. And the decrements which produce the secondary faces are always made by the abstraction of ranges of these parallelopipeds. Hauy gives to these parallelopipeds the name of *subtractive molecules.* As far as the theory of crystallization is concerned, we have to do only with molecules of the form of parallelopipeds, Indeed, the whole doctrine of the shape of the integrant molecules is entirely hypothetical.

5. When the nucleus is not a parallelopiped, we may always substitute in place of it a solid of that form, either by abstracting some of the faces if there are more than six, or by multiplying the subdivisions in the direction of the natural joints if it is a tetrahedron. But simpler results are often obtained by giving the preference to the true nucleus.

6. The decrements which the plates of superposition undergo, may take place in every possible direction. The limits of these directions are the edges and the diagonals of the faces of the nucleus. Between these two limits there are an infinity of intermediate directions, according as the molecules, the ranges of which determine the decrement, are conceived to be single, double, triple, &c. When the decrements are parallel to the edges, they are called *decrements on the edges;* when parallel to the diagonals, they are called *decrements on the angles;* and when they are parallel to lines intermediate between the edge and diagonal, they are called *intermediate decrements.*

Let us now run over all the primitive forms, giving, with respect to each, the method of calculating the results of all the laws of decrement of which they are susceptible; and beginning with the parallelopiped, which is the term of comparison to which the other forms are referred.

Mathematical Theory.

PLATE CCXXIII. Fig. 35.

Theory of the parallelopiped.

II. *Theory of the Parallelopiped.*

Let AG (Fig. 35.) be a parallelopiped, the faces of which have any dimensions, and the angles any size at pleasure. Let us conceive this solid to be subdivided by planes parallel to its different faces into a multitude of elementary parallelopipeds, which constitute its integrant molecules. Each of its faces will be divided, of course, into a multitude of small parallelograms, which constitute the bases of as many molecules. If we choose any two of the six faces of this solid, provided that they be opposite, we may consider the solid as an assemblage of plates divided from each other by planes parallel to these faces.

Suppose, now, that new plates formed of small parallelopipeds, similar and equal to the preceding, are applied to the different faces of the parallelopiped, so that the faces in contact exactly coincide, just as is the case in the interior of the solid. There are three separate cases, which may be distinguished. First, The plates may extend by their edges in such a manner as exactly to inclose the nucleus, which will thus increase in size without altering its shape. Secondly, The plates may continue of the same size as the face of the nucleus to which they are applied; in which case, it is easy to see, that re-entering angles would be formed at the edges DC, BC, CG, &c. Thirdly, The plates may progressively decrease in certain directions, so that each will be passed by the preceding plate by a quantity equal to one or more ranges, either in breadth or height.

Of these three cases, the first relates to the primitive forms given immediately by crystallization, and is attended with no difficulty. The second is excluded by the laws of crystallization, no example of it ever occurring. The third constitutes the object of the theory.

Let us suppose, first, that the decrements take place in breadth on all the edges, by the subtraction of an equal number of ranges; and let us confine ourselves to consider the effect of the decrement which takes place parallel to the edge BC, upon the face ABCD.

If we suppose that the form of the integrant molecule (which is similar to the nucleus) is determined, and that the law of decrement is known, it will be easy to find the angle which ABCD makes with the face produced in consequence of the decrement. Let

Fig. 36. ag (Fig. 36.) be one of the molecules, whose faces, analogous to those of the parallelogram Fig. 37, are marked by the same letters. From the point c, draw cs and cr perpendicular to bc. But the ratio between these two lines is given by hypothesis, as is also the angle rcs, which measures the inclination of the faces $abcd$ and $bcgh$.

Now, let op (Fig. 35.) be the distance between the edge BC and the first plate of superposition, which distance is conceived to be measured upon the plane ABCD. It is evident, that op is equal to cr (Fig. 36.) multiplied by the number n of ranges subtracted, or $op = n \times cr$. From the point p (Fig. 36.) raise pu upon the lateral face of the first plate of superposition, and equal to that plate in height. We shall have $pu = cs$ (Fig. 36.), and $opu = scr$. Complete the triangle upo (Fig. 35.) It is evident, that the line ou will coincide with the secondary face of the crystal produced upon the edge BC, and that the angle pou will measure the incidence of that face upon the parallelogram ABCD. Now, as in the triangle upo, we know the two sides op, pu, and the included angle opu, it will be easy to find the angle pou, and therefore to obtain the incidence sought for. The triangle pou is called the *measuring triangle* by Hauy, and the same name is applied to all triangles performing the same function.

Let us now consider the effect of the decrement parallel to the same edge BC, but upon the parallelogram BCGH. Let oih be the *measuring triangle*, in which oi is the distance between the edge BC and the first plate of superposition, ih coincides with the lateral face of the same plate, and is equal to it in height, and oh coincides with the new face produced by the decrement.

Let n' be the number of ranges subtracted. We will have oi (Fig. 35.) $= n' \times cs$ (Fig. 36.); and ih (Fig. 35.) $= cr$ (Fig. 36.); and $oih = rcs$. Hence it will be easy to determine the angle which the face produced by decrement makes with BCGH (Fig. 35.) PLATE CCXXIII. Figs. 35, 36.

It may happen, that the two decrements which act upon the sides of BC, have such a relation to each other, that the two faces resulting from them coincide in the same plane, so that the side oh of the triangle oih is a continuation of the side ou of the triangle opu, as is represented in Fig. 37. To prove this, let us observe, that in this case the two triangles upo, oih are similar, both on account of the equality of the angles opu, hio, as of the parallelism of the sides op, ih, and the coincidence of the sides ou, ho, in the same direction. Hence Fig. 37.

$pu : op :: oi : ih$; or, which is the same thing,
cs (Fig. 36.) : $n \times cr :: n' \times cs : cr$. This gives us Fig. 36.

$$n' = \frac{1}{n}.$$

That is to say, that the two faces will be in the same plane whenever the decrements in the direction BC to GH are inversely, as those in the direction BC to AD; or, which comes to the same thing, when there is on one side a decrement in height equal to what takes place in breadth on the other. It is obvious also, that the two faces will be in the same plane when the decrement proceeds on both sides by one range.

Hence in all such cases, we may abstract one of the decrements altogether, and consider the face as a continuation of that which proceeds from the other decrement.

From what has been said, the method of proceeding to determine the incidences of the secondary faces upon all the other faces of the nucleus is obvious.

The greatest number of faces which a secondary solid can have from such decrements is 24, since the nucleus has twelve edges, each of which is capable of giving origin to two faces. These new faces will be all triangles, or partly triangles and partly trapeziums, according as the nucleus is or is not more or less elongated in one direction than in the other; or according as the decrements parallel to certain edges follow a more rapid law than the other decrements. The smallest number of faces which the secondary crystal can have is 12. In that case, all the decrements proceeding from the same edge are the inverse of each other. The simplest case is that in which the nucleus is a cube, and we have $n=1$, $n'=1$. In that hypothesis, the secondary crystal is a rhomboidal dodecahedron, as was shewn in the last Chapter.

Let us now determine, in the same manner, the decrements on the angles. The secondary faces formed by such decrements are called by Hauy *lateral faces*. Let us suppose, that decrements take place in

Mathematical Theory.

Plate CCXXIII. Fig. 35.

breadth by the same number of ranges on all the angles of the parallelopiped (Fig. 35.); and let us take, as an example, that which takes place upon the angle BCD. Let C kl be the measuring triangle, in which C k measures the distance between the point C and the first plate of superposition; kl is applied to the lateral face of that plate, and measures its height, and C l coincides with the secondary face, produced by the decrement under consideration.

Fig. 36.

Having drawn the diagonals db, fh (Fig. 36.) on the bases of the molecule, let fall ct perpendicular to db, and xz perpendicular both to db and to fh. Let N be the number of ranges abstracted. We will have C k (Fig. 35.) $=$ N $\times$ ct (Fig. 36.), and kl (Fig. 35.) $= xz$ (Fig. 36.); and the angle C kl (Fig. 35.) will be equal to that which the plane $bdfh$ (Fig. 36.) forms with the plane fgh. But as these three quantities are known, hence it will be easy to find kCl (Fig. 35.) which measures the inclination of the new face to the parallelogram ABCD. The effect of the decrements on the other angles is calculated in the same manner.

Fig. 38.

Let us now consider the hypothesis in which the decrements that take place upon the two angles DCG, BCG have such a ratio to that which takes place upon the angle BCD, that the faces produced by the three decrements coincide in one plane. Let AG (Fig. 38.) be the nucleus as before. Let us suppose the decrement which takes place in breadth upon the angle BCD has such a measure, that the edge of the first plate of superposition passes by mr. In which case, each of the lines Cm, Cr will include as many lengths of molecules equal to cd or cb, (Fig. 36.) as there are ranges abstracted by the decrement. Having taken upon CG (Fig. 38.) a part Cc equal to cg, (Fig. 36.) let a plane pass through the points m, c, r. This plane is parallel to the face that will be produced by decrement. To prove this, draw the indefinite lines ms and ru parallel to CG, and prolong them above the nucleus, so as to make Mm or Rr equal to Cc. It is evident that Mm and Rr represent two faces situated on the side of the first plate; therefore the face produced by the decrement passes through the points M, R. It likewise passes through C, which is the point from which the decrement set out; therefore the plane MCR coincides with the face produced by the decrement. But the lines Cc, Mm, Rr, being three longitudinal edges of the molecules, situated parallel to each other between the two planes mcr, MCR, these two planes must be parallel. That is to say, mcr is parallel to the face produced by the decrement.

The same reasoning applies to the hypothesis when the decrements take place in height. In that case, it would be necessary, in order that the plane mcr were parallel to the face produced, to have $cm = cd$, (Fig. 36.) $cr = cb$, and that the line Cc (Fig. 38.) should contain as many times cg (Fig. 36.) as there are ranges subtracted in height.

Suppose the plane MCR to be prolonged above the faces CDFG, BCGH, and let us consider these prolongations as two faces that would have the effect of two decrements, the one upon the angle DCG, the other upon BCG. These decrements being equal, we may confine ourselves to that which takes place upon the angle DCG. Since the plane cmr is parallel to the face which results from the decrement, it is clear, that cm coincides with the inferior border of the first plate of superposition applied upon CDFG; and that Cr contains as many lengths of molecules as there are molecules subtracted in height.

If the decrement relative to the angle BCD takes place by one range, it is evident, that the two other decrements on the angles DCG and BCG will likewise take place by one range, because, in that case, the three lines Cm, Cr, Cc, being each equal to the length of one molecule, must of course have the same measure.

But if the decrement relative to the angle BCD take place by more than one range, then the two others will be necessarily intermediate, and it will be sufficient to have the law of the first decrement to determine the two others. Suppose, for example, that the decrement on the angle BCD takes place by three ranges in breadth. In that case, Cm and Cr will be equal each to the length of three molecules, and Cc will be equal to one length. Then the decrement on the angle DCG takes place in such a manner, that there are three lengths of a molecule subtracted along CD, and only one along CG; and this decrement takes place by three ranges in height, since Cr corresponds with three lengths of a molecule. The same rule holds with the decrement on the angle BCG.

In all cases of this nature, the theory considers only the decrements which take place according to the ordinary laws; because a much more simple solution results from it. The two other decrements are considered as subsidiary, and as coming to second the effect of the first, and to continue it over the parts adjacent to the face which it has produced.

The greatest number of faces which a secondary crystal can have on the hypothesis of a decrement, on all its angles, is 24; because there are eight solid angles, composed each of three plane angles, which are the terms from which as many decrements set out. The smallest number of faces, according to the same hypothesis, is eight. And though, in fact, there are always 24 decrements, yet eight only are considered; which enables us to apply the ordinary laws to determine the figure of the secondary crystal. The most simple case is that in which the nucleus is a cube, and all the decrements take place by one range. The result is the regular octahedron, as we saw in the last Chapter.

But it may happen that the three decrements which take place round the same solid angle, are intermediate. In that case, it is sufficient to determine one of them, in order to be able to judge of the two others, by means of a construction similar to that which we have already employed.

Plate CCXXIV. Fig. 3.

Let Fig. 3. represent the nucleus, marked with letters, according to the rules laid down in the last Chapter for writing the symbols of crystals. Let us conceive that a decrement takes place on the angle O, ascending, which produces a face parallel to the plane nrs, and of which the expression is $(\overset{2}{O}\ D^3\ F^4)$. From this it follows, that O$n = 3\,cd$, (Fig. 36.) O$r = 4\,cb$, and O$s = 2\,cg$.

Plate CCXXIII. Fig. 36.

The expression of the decrement on the left of the angle O will be $({}^4O\ D^3\ H^2)$ and that of the decrement on the right of the same angle $(O^3\ F^4\ H^2)$.

To determine the angles which the faces produced by intermediate decrements make with the corresponding faces of the nucleus, the most simple method is to consider each little group of molecules which results from the decrement, as forming a single molecule, which brings the calculus to that which is employed for the ordinary decrements on the angles. Let us take, as an example, the decrement upon the angle O, ascending, represented by the symbol $(\overset{2}{O}\ D^3\ F^4)$. It is easy to judge, that in this case, the group which represents the

Mathematical Theory.

PLATE CCXXIV. Fig. 4.

molecule subtracted, is that which is represented in Fig. 4, in which the side mn is composed of three lengths of molecules, the side np of four lengths, and the side nk of two lengths, in consequence of a decrement by two ranges in height.

Fig. 5.

Having drawn upon the bases the diagonals mp, io, let fall nt perpendicular to mp, and us perpendicular both to mp and io. Let nty (Fig. 5.) be the measuring triangle, in which nt being conceived to coincide with the plane, AEOI (Fig. 3.) will be equal to nt. (Fig. 4.) We will likewise have ty (Fig. 5.) $=us$, (Fig. 4.) and the angle nty (Fig. 5.) will be equal to that which the plane $mpoi$ (Fig. 4.) makes with the triangle iko. Hence it will be easy to find the angle ynt (Fig. 5.) which measures the inclination wanted.

The solution of problems of this kind is often simplified in practice, in consequence of the regular form of the molecules. Let us suppose, for example, that they are cubes; and let us give to each of their edges the value of unity. We have, in such a case, (Fig. 4.) $mn=3$, $np=4$, $nk=2$, $mp=\sqrt{(mn)^2+(np)^2}=\sqrt{25}=5$; $nt=\frac{mn\times np}{mp}=\frac{12}{5}$; and $us=nk=2$. Hence, nt (Fig. 5.) $=\frac{12}{5}$ and $ty=2$. And

$$nt : ty :: \tfrac{12}{5} : 2 :: 6 : 5.$$

In this case the angle nty is right. Hence we see how easy it is in such a case to find the angle ynt.

Fig. 6.

The measuring triangles, relative to the decrements on the angles, may be substituted for those which we have considered in the decrements on the edges, and will serve equally to determine the secondary forms. Suppose, for example, that AG (Fig. 6.) represents a cubic nucleus, which undergoes decrements by two ranges upon the four edges of the base ABCD, and that we wish to know the angle of the pyramid sADCB produced by this decrement. Having drawn the diagonals BD, AC, let fall from their point of intersection o the line op perpendicular to CD. Draw sp. Upon op take the part pr, equal to two lengths of a molecule, and from r draw ru perpendicular upon the plane ABCD, and which, by hypothesis, is equal to the length of one molecule. The triangle upr will perform the function of the ordinary measuring triangle; and by means of the right angle urp and the ratio 2 : 1 between the sides pr and ur, it will be easy to find the incidence of DsC on the base ABCD, as well as the values of the other angles. For on account of the similar triangles upr, spo, the whole is reduced to calculate the angles of a right pyramid, in which the side BC of the base, which is double of po, is to the axis os as 4 to 1.

On the other hand, if we take upon Co the part Cn equal to two diagonals of the molecule, and from the point n raise nz perpendicular upon ABCD, Cn will represent the distance of the point C from the first plate of superposition, taken in the direction Co, and nz will be equal to the length of a molecule; hence it follows, that the triangle zCn may also perform the office of a measuring triangle. We will have C$n : nz :: 2\sqrt{2} : 1$; and because the triangle zCn is similar to the triangle sCo, the question considered in this new point of view is reduced to find the angles of a right pyramid, in which the demidiagonal Co of the base is to the axis os as $2\sqrt{2} : 1$. It is usual in this manner to substitute one measuring triangle for another, when there results, in consequence, a greater facility of calculation.

The preceding details may be considered merely as introductory observations, in order the better to explain the nature and importance of the *measuring* triangles. Let us now proceed to the method of calculating, and let us begin with the *rhomboid*, which (including the cube,) affords the easiest application of the theory, and at the same time the most varied results.

Algebraic expressions for the rhomboid.

PLATE CCXXIV. Fig. 7.

The first object to be attained, is the algebraic expressions for the principal lines in the rhomboid. Let Fig. 7. represent an obtuse rhomboid, because it occurs most usually; though the algebraic expressions will apply equally to any rhomboid whatever. Draw the diagonals bf, ad. The horizontal demidiagonal bc or cf is called g, while the oblique demidiagonal ac or ad is called p.

Fig. 8.

Let $adsg$ (Fig. 8.) be a four-sided figure formed by two opposite oblique diagonals ad, gs of the rhomboid, (Fig. 7.) and by the edges ag, ds included between these two diagonals. Such a figure is called the *principal section of the rhomboid.*

From the point d draw dr perpendicular to the axis as, and from the point g, draw gn, likewise perpendicular to the axis, and continue it till it meets ad. This line will bisect ad. For if the diagonals fg and bg (Fig. 7.) be drawn, the whole line gc (which is the same as in Fig. 8.) will be situated in the plane bfg (Fig. 7.) which passes through the point c. It is evident, likewise, that cn, which is a perpendicular drawn from the centre of the equilateral triangle bfg, is half the length of gn, which goes from the centre to one of the angles of this triangle. Now, gn is called the *perpendicular to the axis,* and cn the *semiperpendicular to the axis.*

The following are the algebraical expressions for the different edges of the rhomboid, in functions of g and p.

1. ab (Fig. 7.) $=\sqrt{(bc)^2+(ac)^2}=\sqrt{g^2+p^2}$.

2. $bf=2g$; $cg=\sqrt{\frac{4}{3}g^2}$; $cn=\sqrt{\frac{1}{3}g^2}$.

3. The perpendiculars gn and dr (Fig. 8.) divide the axis into three equal parts. For the similar triangles acn, adr, give $ad : ac :: ar : an$. But $ad=2ac$, therefore $ar=2an$. And the triangles dsr, gan being similar and equal, we have $rs=an$. Therefore, $an=nr=rs$. But $an=\sqrt{(ac)^2-(cn)^2}=\sqrt{p^2-\frac{1}{3}g^2}$. Hence, $as=3\sqrt{p^2-\frac{1}{3}g^2}=\sqrt{9p^2-\frac{9}{3}g^2}=\sqrt{9p^2-3g^2}$.

PROBLEM. Given the demidiagonals g and p to determine, in a general manner, three species of angles, namely, the plane angles of the rhomboid, the inclination of the respective faces, and the angles of the principal section.

1. For the plane angles, draw am (Fig. 7.) perpendicular to df, am will be the sine of the angle afd, supposing af as radius. Let us find the ratio between af and the cosine fm.

We have already $af=\sqrt{g^2+p^2}$.

Now, $am=\dfrac{bf\times ac}{df}=\sqrt{\dfrac{4g^2p^2}{g^2+p^2}}$.

Hence, fm or $\sqrt{(af)^2-(am)^2}=\sqrt{g^2+p^2-\dfrac{4g^2p^2}{g^2+p^2}}$

$$=\sqrt{\frac{g^4-2g^2p^2+p^4}{g^2+p^2}}.$$

Hence it follows, that $af : fm :: g^2+p^2 : \pm g^2 \mp p^2$. The upper signs of the last term belonging to the case when the rhomboid is obtuse, the lower to that in which it is acute.

This result gives us a remarkable property of the

Mathematical Theory.

rhomboid. The cosine of its smaller plane angle is always a rational quantity, provided the expressions for the squares of the diagonals be rational.

2. For the inclination of the respective faces, as, for example, that of $a\,b\,d\,f$ or $d\,f\,g\,s$. From the point m, draw $m\,i$ perpendicular to $d\,f$, and prolonged till it meet $f\,s$. The angle $a\,m\,i$ measures the inclination wanted: $a\,i$ is the sine of that angle, taking $a\,m$ for radius. We have only to discover the ratio between $a\,m$ and $i\,m$, the cosine.

We have already $a\,m = \sqrt{\dfrac{4\,g^2\,p^2}{g^2+p^2}}$.

PLATE CCXXIV. Fig. 7, 8.

Draw $a\,k$ (Fig. 8.) perpendicular to $g\,s$; it will be equal to $a\,i$ (Fig. 7.) Now, $a\,k = \dfrac{g\,n \times a\,s}{g\,s} = \sqrt{\dfrac{\frac{4}{3}g^2\,(9\,p^2-3\,g^2)}{4\,p^2}} = \sqrt{\dfrac{3\,g^2\,p^2-g^4}{p^2}} = a\,i$.

Therefore, $a\,m : a\,i :: \sqrt{\dfrac{4\,p^2}{g^2+p^2}} : \sqrt{\dfrac{3\,p^2-g^2}{p^2}}$. And $a\,m : i\,m :: \sqrt{\dfrac{4\,p^2}{g^2+p^2}} : \sqrt{\dfrac{4\,p^2}{g^2+p^2} - \left(\dfrac{3\,p^2-g^2}{p^2}\right)} :: 2\,p^2 : g^2 - p^2$.

If the rhomboid is acute, the proportion will be $a\,m : i\,m :: 2\,p^2 : p^2 - g^2$.

Thus the expression for the cosine of the angle of incidence is rational, as well as of the plane angle of the rhomboid.

3. For the angles of the principal section, $a\,k$ (Fig. 7.) will be the sine of the angle g, taking $a\,g$ for radius; and from the preceding investigation, it is evident that (comparing together the sine and cosine) we have $a\,k : k\,g :: \sqrt{3\,g^2\,p^2 - g^4} : g^2 - p^2$. If the rhomboid were acute, the proportion would be $\sqrt{3\,g^2\,p^2-g^4} : p^2 - g^2$.

In the rhomboid which constitutes the primitive form of calcareous spar, we have $g = \sqrt{3}$ and $p = \sqrt{2}$ *. If we substitute these values in place of g and p in the preceding proportions, we obtain,

1. $a\,f : f\,m :: 5 : 1$; which gives $f\,a\,m = 11°\ 32'\ 13''$, therefore $b\,a\,f$ is $101°\ 32'\ 13''$.

2. $a\,m : i\,m :: 4 : 1$; which gives for the angle $a\,m\,i$ $75°\ 31'\ 20''$.

3. $a\,k : k\,g$ (Fig. 8.) $:: 3 : 1$; which gives for the angle $a\,g\,s$ $71°\ 33'\ 54''$.

Let us now determine the results of the different laws of decrement of which the rhomboid is susceptible. There are five different kinds of decrement possible, which give secondary forms, namely,

1. A decrement on the superior edges $a\,b$, $a\,f$.
2. A decrement on the superior angle a.
3. A decrement on the inferior edges $d\,b$, $d\,f$.
4. A decrement on the lateral angles b, f.
5. A decrement on the inferior angle d.

We shall consider here only the secondary forms resulting from a decrement by one range of molecules.

1. *Decrements on the Superior Edges.*

Decrements on the superior edges.

These decrements in general produce dodecahedrons, with triangular faces, three edges of which, taken alternately, will coincide with the edges $a\,b$, $a\,f$, $a\,g$, &c. of the nucleus (Fig. 7.) and the others will be raised above the oblique diagonals $a\,d$, $a\,q$, &c. The axis of the secondary crystal will be the same as the axis of the nucleus.

Fig. 9.

Let $a\,d\,s\,g$ (Fig. 9.) be the principal section of the nucleus, $a\,m$ the edge of the secondary crystal which rises above the diagonal $a\,d$, and which must be in the plane that passes through a, d, s; let $s\,m$ be the lower corresponding edge, which coincides with the edge $s\,d$ of the primitive rhomboid.

PLATE CCXXIV. Fig. 9.

Let $a\,z\,t$ be the measuring triangle, which we will consider here as if the decrements took place upon the angle a, observing, that to one range of molecules subtracted towards the edges $a\,b$, $a\,f$ (Fig. 7.) corresponds the oblique diagonal of a molecule, which measures the quantity that one plate of superposition passes another.

The first point is to determine the ratio between the sides $a\,z$ and $t\,z$ of this triangle. Let a be the length of a molecule, and p' its oblique semidiameter. Calling n the number of diameters subtracted, we have $a\,z : t\,z :: 2\,p' \times n : a$; and, because the dimensions of a molecule are proportional to those of the nucleus, $a\,z : t\,z :: 2\,n\,p : \sqrt{g^2+p^2}$.

Let us determine likewise the ratio between $m\,u$ perpendicular to the axis relative to the secondary dodecahedron, and the part $a\,u$ of the axis comprehended between the summit and that perpendicular.

1. For $m\,u$. The similar triangles $m\,s\,u$, $d\,s\,r$, give $d\,s : d\,r :: s\,m : m\,u$. But $d\,s = \sqrt{g^2+p^2}$ and $d\,r = \sqrt{\frac{4}{3}\,g^2}$. We only want to know $s\,m$, or rather its part $d\,m$, since the rest of it is known. The similar triangles $a\,z\,t$, $a\,d\,m$, give $a\,z : t\,z :: a\,d : d\,m$, or $2\,n\,p : \sqrt{g^2+p^2} :: 2\,p : d\,m = \frac{1}{n}\sqrt{g^2+p^2}$. Therefore $s\,m = \sqrt{g^2+p^2} + \frac{1}{n}\sqrt{g^2+p^2} = \frac{n+1}{n}\sqrt{g^2+p^2}$. Hence the proportion $d\,s : d\,r :: s\,m : m\,u$, becomes $\sqrt{g^2+p^2} : \sqrt{\frac{4}{3}\,g^2} :: \frac{n+1}{n}\sqrt{g^2+p^2} : m\,u = \frac{n+1}{n}\sqrt{\frac{4}{3}\,g^2}$.

2. For $a\,u$. Let us find $s\,u$, and subtract it from $a\,s$.

We have $d\,s : r\,s :: s\,m : s\,u$, or $\sqrt{g^2+p^2} : \frac{1}{3}\sqrt{9\,p^2-3\,g^2} :: \frac{n+1}{n}\sqrt{g^2+p^2} : s\,u = \frac{n+1}{3\,n}\sqrt{9\,p^2-3\,g^2}$. Therefore $a\,u = \sqrt{9\,p^2-3\,g^2} - \left(\frac{n+1}{3\,n}\right)\sqrt{9\,p^2-3\,g^2} = \frac{2\,n-1}{3\,n}\sqrt{9\,p^2-3\,g^2}$. Hence $m\,u : a\,u :: \frac{n+1}{n}\sqrt{\frac{4}{3}\,g^2} : \frac{2\,n-1}{3\,n}\sqrt{9\,p^2-3\,g^2}$.

Fig. 10.

Let $b'\,a\,m$, $f'\,a\,m$, (Fig. 10.), be two neighbouring faces situated towards the superior summit of the secondary dodecahedron, and so chosen that the edges $a\,b'$, $a\,f'$, coincide with those marked with the same letters in Fig. 7; in which case, the edge $a\,m$ (Fig. 10.) will be that which rises above the diagonal $a\,d$ (Fig. 7.)

The semidiameters of the nucleus g and p, and the number n of decrements being given, let us determine the incidence of $b'\,a\,m$ (Fig. 10.) on $f'\,a\,m$, and that of $b'\,a\,m$ on the face adjacent to it, on the other side of $a\,b'$.

Let us suppose a plane $b'\,y\,f'$ perpendicular to the axis $a\,o$. Draw $b'\,o$, $f'\,o$, $y\,o$, upon this plane, and $f'\,r$, $f'\,p$, perpendicular the one to $y\,o$, the other to $a\,y$,

* These ratios are probably not quite correct. Hence some little error in the angles found.

Mathematical Theory.

and join the points p, r. The angle $f' p r$ will be equal to one half of the angle, which gives the incidence of $b' a y$ upon $f' a y$. Draw $y e$, $y h$, perpendicular the one to $b' o$, the other to $a b'$, then join the points e, h. The angle $y h e$ will be the half of that which measures the incidence $b' o y$ on the adjacent face $a b$. We will therefore obtain the two incidences wanted, if we find the ratio between the sine $f' r$ and the cosine $p r$ of the angle $f' p r$, and the ratio between the sine $y e$ and the cosine $e h$ of the angle $y h e$.

PLATE CCXXIV. Fig. 9, 10.

Having produced $g n$ (Fig. 9.) till it meets $a m$, we may suppose, for the greater simplicity, that the plane $b' y f' o$ (Fig. 10.) is of the same height as $g x$ (Fig. 9.), so that $a o$ (Fig. 10.) $= a n$ (Fig. 9.) In that case, we shall have likewise $f' o$ or $b' o$ (Fig. 10.) $= g n$ (Fig. 9.), and $y o$ (Fig. 10.) $= n x$ (Fig. 9.)

Let us obtain separately $f' r$ and $p r$.

1. For $f' r$. It is evident that $f' r$ is the half of the line which joins the points b, f'; and since these points re conceived to be of the same height as $g x$, they concide with the points b, f (Fig. 7.) Hence it follows at $f' r$ (Fig. 10.) $= b c$ (Fig. 7.) $= g$.

2. For $p r$. The triangles $a o y$, $r p y$ (Fig. 10.) are similar, from their position, and the equality of the angles $a o y$, $r p y$, both right angles. Hence $a y : a o :: y r : p r$. Let us obtain values of $a y$, $a o$, and $y r$.

$$a y = \sqrt{(y o)^2 + (a o)^2}\,;\ y o = n x \text{ (Fig. 9.)}$$

$$a u : m u :: a n : n x, \text{ or}$$

$$\frac{2n-1}{3n}\sqrt{9p^2 - 3g^2} : \frac{n+1}{n}\sqrt{\tfrac{4}{3}g^2} :: \tfrac{1}{3}\sqrt{9p^2 - 3g^2}$$

$$: n x = \frac{n+1}{2n-1}\sqrt{\tfrac{4}{3}g^2} = y o \text{ (Fig. 10.)}$$

$a o = \frac{1}{3}\sqrt{9p^2 - 3g^2}$. Let us, for greater simplicity, denote the value of the axis $\sqrt{9p^2 - 3g^2}$ by a, we will have $a y = \sqrt{\left(\frac{n+1}{2n-1}\right)^2 \frac{4}{3} g + \frac{1}{9} a^2}$.

We still want $y r$. The angle $f' o r$ being an angle of $60°$, and the angle $f r s$ of $90°$, or $= \frac{1}{2} f' o = \frac{1}{2}\sqrt{\frac{4}{3}g^2}$

$$y r = y o - o r = \frac{n+1}{2n-1}\sqrt{\tfrac{4}{3}g^2} - \tfrac{1}{2}\sqrt{\tfrac{4}{3}g^2} =$$

$$\frac{3}{2n-1}\sqrt{\tfrac{1}{3}g^2}.$$

Therefore the proportion $a y : a o :: y r : p r$ becomes

$$\sqrt{\left(\frac{n+1}{2n-1}\right)^2 \tfrac{4}{3}g^2 + \tfrac{1}{9}a^2} : \sqrt{\tfrac{1}{9}a^2} :: \frac{3}{2n-1}\sqrt{\tfrac{1}{3}g^2} :$$

$$p r = \frac{\frac{1}{2n-1}\sqrt{\frac{1}{3}a^2 g^2}}{\sqrt{\left(\frac{n+1}{2n-1}\right)^2 \frac{4}{3}g^2 + \frac{1}{9}a^2}}.$$

$$\text{Hence } f' r : p r :: g : \frac{\frac{1}{2n-1}\sqrt{\frac{1}{3}a^2 g^2}}{\sqrt{\left(\frac{n+1}{2n-1}\right)^2 \frac{4}{3}g^2 + \frac{1}{9}a^2}} ::$$

$$\sqrt{\left(\frac{n+1}{2n-1}\right)^2 \tfrac{4}{3}g^2 + \tfrac{1}{9}a^2} : \frac{1}{2n-1}\sqrt{\tfrac{1}{3}a^2} ::$$

$$\sqrt{(n+1)^2\, 4 g^2 + (2n-1)^2 \tfrac{1}{3} a^2} : a.$$

Let us now find the ratio between the sine $y e$ and the cosine $e h$ of the angle $y h e$.

1. For $y e$. We have $y e = \sqrt{(y o)^2 - (o e)^2}$; $y o^2 = \left(\frac{n+1}{2n-1}\right)^2 \frac{4}{3} g^2$, as before determined. Further, on account of $e o y = 60°$, and $y e o = 90°$, we have $o e = \frac{1}{2} y o$. Hence $y e = \sqrt{\frac{1}{4}(y o)^2} = \sqrt{\left(\frac{n+1}{2n-1}\right)^2 g^2}$.

Mathematical Theory.

2. For $e h$. The similar triangles $b' o a$, $b' h e$, give $a b' : a o :: b' e : e h$. Now,

$$a b' = \sqrt{(b' o)^2 + (a o)^2} = \sqrt{\tfrac{4}{3}g^2 + \tfrac{1}{9}a^2}$$

$$a o = \sqrt{\tfrac{1}{9}a^2}$$

$$b' e = b' o - o e = \sqrt{\tfrac{4}{3}g^2} - \left(\frac{n+1}{4n-2}\right)\sqrt{\tfrac{4}{3}g^2} =$$

$$\left(1 - \left(\frac{n+1}{4n-2}\right)\right)\sqrt{\tfrac{4}{3}g^2} = \frac{3n-3}{4n-2}\sqrt{\tfrac{4}{3}g^2}.$$

Therefore the proportion $a b' : a o :: b' e : e h$, becomes

$$\sqrt{\tfrac{4}{3}g^2 + \tfrac{1}{9}a^2} : \sqrt{\tfrac{1}{9}a^2} :: \frac{3n-3}{4n-2}\sqrt{\tfrac{4}{3}g^2} : e h.$$

Therefore

$$e h = \frac{\frac{3n-3}{4n-2}\sqrt{\frac{4}{27}a^2 g^2}}{\sqrt{\frac{4}{3}g^2 + \frac{1}{9}a^2}} = \frac{\frac{n-1}{2n-1}\sqrt{\frac{1}{3}a^2 g^2}}{\sqrt{\frac{4}{3}g^2 + \frac{1}{9}a^2}} =$$

$$\frac{n-1}{2n-1}\sqrt{\frac{3a^2 g^2}{12g^2 + a^2}}.$$

Therefore

$$y e : e h :: \sqrt{\left(\frac{n+1}{2n-1}\right)^2 g^2} : \frac{n-1}{2n-1}\sqrt{\frac{3a^2 g^2}{12g^2 + a^2}} :: n+1 :$$

$$(n-1)\sqrt{\frac{3a^2}{12g^2 + a^2}} :: (n+1)\sqrt{12g^2 + a^2} : (n-1)\sqrt{3a^2} ::$$

$$(n+1)\sqrt{12g^2 + 9p^2 - 3g^2} : (n-1)\sqrt{27p^2 - 9g^2} :: (n+1)$$

$$\sqrt{g^2 + p^2} : (n-1)\sqrt{3p^2 - g^2}.$$

There is a variety of calcareous spar, whose summits have each six faces resulting from a decrement by three ranges upon the superior edges of the nucleus, and which combine with other intermediate faces, of which we do not take any notice. To apply the above formulæ to this variety of crystal, we must make $n = 3$, $g = \sqrt{3}$, $p = \sqrt{2}$.

When these values are substituted, we get

1. $b' r : p r :: \sqrt{89} : \sqrt{3}$, which gives $79°\ 35'\ 47''$ for the angle $f' p r$, and $159°\ 11'\ 34''$ for the incidence of $b' a m$ on $f' a m$.

2. $y e : e h :: \sqrt{20} : \sqrt{3}$, which gives $68°\ 49'\ 43''$ for the angle $y h e$, and $137°\ 39'\ 26''$ for the incidence of $b' a m$ on the adjacent face $a b'$.

Let us examine whether there be a possible law of decrement for the dodecahedron with isosceles triangular faces, or composed of two right pyramids applied base to base. In that case, $y o = b' o$. Hence likewise $n x$ (Fig. 9.) $= g n$, or $\frac{n+1}{2n-1}\sqrt{\frac{4}{3}g^2} = \sqrt{\frac{4}{3}g^2}$. This gives $n = 2$. Hence the form is possible by means of a decrement by two ranges.

PLATE CCXXIV. Fig. 9.

In proportion as the edge $a m$ is elevated by its lower extremity, by making the angles larger with the axis $a o$ (Fig. 10.), the angle which $b' a m$ makes with the face adjacent to $a b'$ increases in size, and there is a term when these two faces are in the same plane. The secondary crystal becomes then a rhomboid, the oblique diagonals of which coincide with the edges $a b'$, $a f'$, &c.

Fig. 10.

To find the law which produces this rhomboid, let it be observed, in the first place, that when it takes place, the cosine eh disappears; so that, in that case, $\frac{n-1}{an-1}\sqrt{\frac{3a^2g^2}{12g^2+a^2}}=0$, or $n-1=0$. Hence $n=1$. This was already evident, from what was said before.

Plate CCXXIV. Fig. 9.

Let us determine the two demidiagonals of this rhomboid. Let g' and p' be these two lines; sm (Fig. 9.) being the oblique diagonal of the rhomboid, mu will be the perpendicular upon the axis. Then $mu=\sqrt{\frac{4}{3}g'^2}$. But on the other hand, $mu=\frac{n+1}{n}\sqrt{\frac{4}{3}g^4}=2\sqrt{\frac{4}{3}g^2}$. Hence $g'=2g$.

In this case, the line mu is elevated so as to be in the direction of gn. This is a a necessary consequence of sm being the oblique diagonal. Hence $su=2sr$, and $sm=2sd$. So that $2p'=2\sqrt{g^2+p^2}$ or $p'=\sqrt{g^2+p^2}$. That is to say, that the horizontal demidiagonal g' is double that of the nucleus, and that the oblique demidiagonal p' is equal to the edge of the nucleus.

This case exists in a variety of crystals, and particularly in that variety of calcareous spar which Hauy has called *equiaxe*. In it $g=\sqrt{3}$, $p=\sqrt{2}$. Hence $g'=\sqrt{12}$, and $p'=\sqrt{5}$. From these data, it is easy to determine the angles, employing the formulæ above explained.

Let us suppose that the secondary crystal is a cube, and let us enquire what, in that case, ought to be the ratio between the two demidiagonals of the nucleus. We may make $g'=1$, $p'=1$. Then substituting in the equations $g'=2g$, $p'=\sqrt{g^2+p^2}$, we obtain $1=2g$, or $g=\frac{1}{2}$. $1=\sqrt{g^2+p^2}$, or $1=g^2+p^2=\frac{1}{4}+p^2$. Hence $p=\sqrt{\frac{3}{4}}=\frac{1}{2}\sqrt{3}$. And $g:p::1:\sqrt{3}$. That is to say, that the nucleus is an acute rhomboid, with angles of 60° and 120°. This would be the case with the cube of fluor spar, if, in place of the octahedron, which is the real nucleus, we were to substitute the rhomboid which results from the application of two regular tetrahedrons upon the two opposite faces of the octahedron.

2. *Decrements on the Superior Angle.*

Decrements on the superior angle.

These decrements always give rhomboids for secondary forms. Let us continue to employ Fig 9. in which ao represents the oblique diagonal of one of the faces of the secondary crystal, and so the edge contiguous to that diagonal; so that, if from the point o we draw a perpendicular to the axis, it will coincide with dr, since the point o ought to be situated opposite the third part of the axis. The angle atz, which in the preceding case supplied the place of the measuring angle, becomes here the real measuring angle; and the quantity n will always signify the number of diagonals subtracted, with this difference, that we must double the number to have that of the ranges subtracted.

Let us express, in a general manner, the ratio between the two semidiameters g' and p' of the secondary rhomboid, supposing us to know g, p, and n.

We have, in the first place, $or:ar::\sqrt{\frac{4}{3}g'^2}:\frac{2}{3}\sqrt{gp'^2-3g'^2}$. And because the expressions for mu and au remain the same as in the case of decrements on the superior edges, we will have $or:ar::mu:au::\frac{n+1}{n}\sqrt{\frac{4}{3}g^2}:\frac{2n-1}{3n}\sqrt{9p'^2-3g^2}::\sqrt{\frac{4}{3}g'^2}:\frac{2}{3}\sqrt{9p'^2-3g'^2}$; or, removing the radical signs, and reducing, we have $g'^2:12p'^2-4g^2::(n+1)^2g^2:(2n-1)^2(3p^2-g^2)$.

Taking the product of the extremes and means, and transposing, we get $\left((2n-1)^2 3p^2+(n+1)^2 4g^2-(2n-1)^2g^2\right)g'^2=(n+1)^2 12g^2p'^2$, and developing $(n+1)^2 4g^2-(2n-1)^2g^2$, and reducing, $\left((2n-1)^2 3p^2+(12n+3)g^2\right)g'^2=(n+1)^2 12g^2p'^2$.

Then $g':p'::\sqrt{(n+1)^2 12g^2}:\sqrt{(2n-1)^2 3p^2+(12n+3)g^2}$.

If we suppose the decrement to take place by two ranges, and that the nucleus is a rhomboid, in which $g=\sqrt{9}$, $p=\sqrt{10}$, we will have $n=1$, and the proportion becomes $g':p'::\sqrt{144}:\sqrt{55}$. This result will be found in the variety of oligiste iron ore, or iron glance, called *binaire* by Hauy.

Let us enquire whether, among all the possible secondary rhomboids, there be one similar to that which results from a decrement by one range upon the superior edges.

We have seen that the oblique diagonals of this last rhomboid coincided with the superior edges, such as ag of the nucleus. On the other side am is one of the oblique diagonals of the first rhomboid, and since they are similar, we must have $gan=mau$, and consequence the rectangular triangles ang, aun are likewise similar. Therefore $mu:au::gn:an$. Or $\frac{n+1}{n}\sqrt{\frac{4}{3}g^2}:\frac{2n-1}{3n}\sqrt{a^2}::\sqrt{\frac{4}{3}g^2}:\frac{1}{3}a$. Or $\frac{n+1}{n}:\frac{2n-1}{3n}::1:\frac{1}{3}$. From which we get $n=2$. Hence the decrement will take place by 4 ranges.

If we make $n=\frac{1}{2}$, which is the case when the decrement takes place by one range, we have (taking the ratio between mu and au),

$\frac{n+1}{n}\sqrt{\frac{4}{3}g^2}:\frac{2n-1}{3n}\sqrt{a^2}::(3n+3)\sqrt{\frac{4}{3}g^2}:(2n-1)\sqrt{a^2}::\frac{9}{2}\sqrt{\frac{4}{3}g^2}:o\sqrt{a^2}$. Thus the ratio between mu and au in the present case becomes infinite, which indicates that the diagonal ao itself is infinite, and of course the face upon which it falls is horizontal. This case occurs in calcareous spar, in the tourmaline, in sulphate of iron, &c. In them, either a second decrement takes place, from which there result lateral faces, whose intersections limit the superior face, or there remain faces parallel to those of the nucleus.

If we suppose now decrements in height, it is easy to see that the faces resulting from them will throw themselves to the opposite side of that where the decrement takes place, so that we shall still have secondary rhomboids, always less and less obtuse as the height of the plates increases. Let us point out the method of calculating the effects of these decrements.

Plate CCXXIV. Fig. 11.

Let $agsd$ (Fig. 11.) be the principal section of the nucleus, and azt the measuring triangle, in which az measures a single range, that is to say, is equal to an oblique semidiameter of a molecule; and tz is equal to as many lengths of molecules as there are ranges subtracted in height.

If we prolong ta above ag, the line ay will coincide with the oblique diagonal of the secondary rhomboid, the principal section of which will be $apsk$.

Having continued sg till it meets ap, draw yu perpendicular to the axis as. We must, in the first place, determine the ratio between uy and au.

1. For uy. The similar triangles sgm, syu give $sg:sy::gm:uy$. But $sg=2p$; $sy=sg+gy$. But we do not know the value of gy. To find it, the similar triangles atz, ayg, give us $az:tz::gy:ag$, or

Mathematical Theory.

$p : n\sqrt{g^2+p^2} :: gy : \sqrt{g^2+p^2}$. Hence $gy=\frac{p}{n}$. And of consequence, $sy=2p+\frac{p}{n}=\frac{2np+p}{n}$. Lastly, $gm=\sqrt{\frac{4}{3}g^2}$.

So that the proportion becomes

$$2p : \frac{2np+p}{n} :: \sqrt{\tfrac{4}{3}g^2} : uy=\frac{2n+1}{2n}\sqrt{\tfrac{4}{3}g^2}.$$

2. For au. $au=as-us=\sqrt{9p^2-3g^2}-us$. But we do not know the value of us. To find it, the triangles smg, suy, give us $sg : sy :: sm : us$, or $2p : \frac{2np+p}{n} :: \frac{2}{3}\sqrt{a^2} : us$. Hence $us=\frac{2n+1}{3n}\sqrt{a^2}$. Therefore we have $au=\sqrt{a^2}-\left(\frac{2n+1}{3n}\right)\sqrt{a^2}=\frac{n-1}{3n}\sqrt{a^2}$.

Therefore we have finally

$$uy : au :: \frac{2n+1}{2n}\sqrt{\tfrac{4}{3}g^2} : \frac{n-1}{3n}\sqrt{a^2} :: (6n+3)\sqrt{\tfrac{4}{3}g^2} : (2n-2)\sqrt{a^2}.$$

Let us now determine, in a general manner, the relation between the two demidiagonals g' and p' of the secondary rhomboid.

In the first place, it is evident that, in the secondary rhomboid, lm is the semiperpendicular upon the axis, and am the third of that axis; and because lm and am are proportional to uy and au, we have

$$(6n+3)\sqrt{\tfrac{4}{3}g^2} : (2n-2)\sqrt{9p^2-3g^2} :: \sqrt{\tfrac{4}{3}g'^2} : \tfrac{1}{3}\sqrt{9p'^2-3g'^2}.$$

And, reducing and suppressing the radical signs, $(2n+1)^2 4g^2 : (2n-2)^2(3p^2-g^2) :: g'^2 : 3p'^2-g'^2$.

Taking the product of the extremes and means, we get $\left((2n-2)^2 3p^2-(2n-2)^2g^2+(2n+1)^2 4g^2\right)g'^2=(2n+1)^2 12g^2p'^2$; and developing the quantities $(2n-2)^2$ and $(2n+1)^2$, then reducing and taking the ratio of g' to p', we obtain

$$g' : p' :: \sqrt{(2n+1)^2 3g^2} : \sqrt{(n-1)^2 3p^2+(3n^2+6n)g^2}.$$

Let $n=\frac{1}{2}$, $g=1$, $p=\sqrt{3}$, as in the acute rhomboid of 60° and 120°, we get $g' : p' :: \sqrt{8} : \sqrt{3}$, a result similar to that to which we would obtain by supposing a decrement by two ranges in breadth upon any two opposite angles of the cubic nucleus. This result, applied to the acute rhomboid, is realized in a variety of *grey copper ore*.

It is remarkable, that the same rhomboids which result from a decrement in breadth upon the superior angle, the faces of which are turned towards the oblique diagonals of the nucleus, are still susceptible of being produced in consequence of a decrement in height, such that their faces correspond with the edges of the nucleus. Let us obtain a formula by means of which, the law being given relative to one of these rhomboids, we may know likewise that upon which the other depends. Let n be, as usual, the number of ranges subtracted by the decrement in breadth, and let n' denote the decrement in height. In order that the two rhomboids should be similar, it is necessary that the ratio between the semiperpendicular on the axis and the third of that axis be equal to each other. Therefore, $\frac{n+1}{n}\sqrt{\tfrac{4}{3}g^2} : \frac{2n-1}{3n}\sqrt{9p^2-3g^2} :: 6n'+3\sqrt{\tfrac{4}{3}g^2} : 2n'-2\sqrt{9p^2-3g^2}$. Or, simplifying, $n+1 : 2n-1 :: 2n'+1 : 2n'-2$. Taking the product of the extremes and means, we have $2nn'+4n=4n'-1$. Hence $n=\frac{4n'-1}{2n'+4}$, and $n'=\frac{4n+1}{4-2n}$.

Let $n'=\frac{1}{2}$, as in the former case. We will then have $n=\frac{5}{7}$; a decrement which has not hitherto been observed in the mineral kingdom. Let $n=2$, then $n'=\frac{9}{0}$ or an infinite quantity. From hence we learn, that in such a case, the line ap coincides with the line ag, that is to say, that the secondary rhomboid is similar to that which results from a decrement by one range on the superior edges of the nucleus.

3. *Decrements on the Inferior Edges.*

Decrements on the inferior edges.

The secondary solids produced by this kind of decrement are always dodecahedrons, with scalene triangular faces, one of the sides of which coincides with one of the edges bd, df, fg, &c. (Fig. 7.) of the primitive rhomboid.

Plate CCXXIV. Fig. 7, 12.

Let $adsg$ (Fig. 12.) be the principal section of this rhomboid, pu the axis of the secondary dodecahedron, pd, du two contiguous edges of that dodecahedron. Let dho be the measuring triangle in which ho is equal to the length of a molecule, and dh to as many oblique diagonals of molecules as there are ranges subtracted. Let n be the number of these diagonals, p' the half of a single diagonal, and g' the half of the horizontal diagonal.

We will have $ho=\sqrt{g'^2+p'^2}$, and $dh=2np'$.

Let us, in the first place, determine the part ap of the axis of the secondary crystal, or the quantity that this axis exceeds in length the axis of the nucleus.

Having produced ga till it meets dp, we will have the similar triangles pal, psd which give us $ds : ps :: al : ap$. But,

1. $ds=\sqrt{g^2+p^2}$.
2. $ps=ap+as=ap+\sqrt{9p^2-3g^2}$.
3. For al. The similar triangles dho, dal, give us $dh : oh :: ad : al$; or

$$2np' : \sqrt{g'^2+p'^2} :: 2p : al=\frac{p}{n}\sqrt{\frac{g'^2+p'^2}{p'^2}}.$$

And because the dimensions of the molecules are proportional to those of the nucleus, we have, by substituting $\frac{g^2+p^2}{p^2}$ for $\frac{g'^2+p'^2}{p'^2}$, $al=\frac{1}{n}\sqrt{g^2+p^2}$.

Hence the proportion $ds : ps :: al : ap$ becomes

$$\sqrt{g^2+p^2} : ap+\sqrt{9p^2-3g^2} :: \frac{1}{n}\sqrt{g^2+p^2} : ap.$$ Therefore $ap=\frac{1}{n-1}\sqrt{9p^2-3g^2}$.

Having thus obtained ap, let us determine the respective coincidences of the faces of the dodecahedron at the edges contiguous to the summit. Let as (Fig. 13.) be the nucleus, and bpd, dpf, fpq three of the faces of the dodecahedron. Draw the horizontal semidiagonal de of the rhomb $dfqs$, then having produced pf, draw dk perpendicular to it, and join the points k, e. The angle dke wil measure half the inclination of dpf to fpq. Fig. 13.

Draw the horizontal semidiagonal fc of the rhomb $abdf$ and fz perpendicular to dp, and join the points c, z. The angle fzc will measure half the inclination of fpd to bpd, and it is easy to see that this incidence will be always greater than the first.

Let us, in the first place, find the value of de and ek. But it is evident that $de=g$. We have only therefore to find ek.

Mathematical Theory.

Plate CCXXIV. Figs. 12, 13.

Let pg (Fig. 12.) be the edge which passes through the points marked by the same letters in Fig. 13. and which is equal to pf. Having drawn sy (Fig. 12.) perpendicular to pg produced and through the point t, the centre of sg, another perpendicular tg to the same line, we have $tg=ek$ (Fig. 13.) To obtain the value of tg, let us find that of its double sy.

The similar triangles png, pys give us $pg:gn::ps:sy$.

1. For pg. We have $pg=\sqrt{(pn)^2+(gn)^2}$, and $pn=ap+an=\frac{1}{n-1}\sqrt{9p^2-3g^2}+\frac{1}{3}\sqrt{9p^2-3g^2}=\frac{n-2}{3n-3}\sqrt{9p^2-3g^2}$. And $gn=\sqrt{\frac{4}{3}g^2}$. Hence $pg=\sqrt{\left(\frac{n+2}{3n-3}\right)^2a^2+\frac{4}{3}g^2}$.

2. $gn=\sqrt{\frac{4}{3}g^2}$, as has been just observed.

3. For ps. We have $ps=ap+as=\frac{1}{n-1}\sqrt{a^2}+\sqrt{a^2}=\frac{n}{n-1}\sqrt{a^2}$.

The proportion $pg:gn::ps:sy$, thus becomes $\sqrt{\left(\frac{n+2}{3n-3}\right)^2a^2+\frac{4}{3}g^2}:\sqrt{\frac{4}{3}g^2}::\frac{n}{n-1}\sqrt{a^2}:sy=\frac{n}{n-1}\sqrt{\frac{\frac{4}{3}a^2g^2}{\left(\frac{n+2}{3n-3}\right)^2a^2+\frac{4}{3}g^2}}$. Taking the half of this expression for the value of ek (Fig. 13.), we will have

$$de:ek::g:\frac{n}{n-1}\sqrt{\frac{\frac{1}{3}a^2g^2}{\left(\frac{n+2}{3n-3}\right)^2a^2+\frac{4}{3}g^2}}::$$
$$\sqrt{\left(\frac{n+2}{3n-3}\right)^2a^2+\frac{4}{3}g^2}:\sqrt{\left(\frac{n}{n-1}\right)^2\frac{1}{3}a^2}.$$

Let us now find the value of fc and cz. But as $fc=g$, we have only to find cz.

From the point a (Fig. 12.), taken at the extremity of the axis, and from the point c, in the centre of ad, draw the lines ax and cz both perpendicular to dp. cz is the same line as in Fig. 13, and ax is its double.

But the similar triangles prd, pxa give $dp:dr::ap:ax$.

As ap and dr are already known, we have only to find dp.

We have $dp=\sqrt{(pr)^2+(dr)^2}$. And $pr=ap+ar=\frac{1}{n-1}\sqrt{a^2}+\frac{2}{3}\sqrt{a^2}=\frac{2n+1}{3n-3}\sqrt{a^2}$. Hence $dp=\sqrt{\left(\frac{2n+1}{3n-3}\right)^2a^2+\frac{4}{3}g^2}$.

The proportion above stated of course becomes $\sqrt{\left(\frac{2n+1}{3n-3}\right)^2a^2+\frac{4}{3}g^2}:\sqrt{\frac{4}{3}g^2}::\frac{1}{n-1}\sqrt{a^2}:ax$. Taking the half of ax, found from this proportion, we get the value of cz (Fig. 13.). Now $fc:cz::g:$

$$\sqrt{\frac{\left(\frac{1}{n-1}\right)^2\frac{1}{3}a^2g^2}{\left(\frac{2n+1}{3n-3}\right)^2a^2+\frac{4}{3}g^2}}::\sqrt{\left(\frac{2n+1}{3n-3}\right)^3a^2+\frac{4}{3}g^2}:$$
$$\sqrt{\left(\frac{1}{1n-}\right)^2\frac{1}{3}a^2}.$$

Mathematical Theory.

Let us now apply the different expressions thus found.

If in the equation $ap=\frac{1}{n-1}\sqrt{9p^2-3g^2}$ we make $n=2$, it becomes $ap=\sqrt{9p^2-3g^2}$, that is to say, that in this case the part of the axis of the dodecahedron which passes the axis of the nucleus on each side, is equal to the axis; or which comes to the same thing, that the axis of the dodecahedron is three times the length of the axis of the nucleus. This property is general.

It may be useful to observe in passing, that the two solids have the same ratio to each other as the axes. We leave the demonstration of this as an exercise to the young crystallographer.

If we make $n=1$, we have $ap=\frac{1}{0}\sqrt{9p^2-3g^2}$. This indicates, that in such a case the axis becomes infinite, and of course the planes produced by the decrements are vertical. This case occurs in the corundum.

Let us resume the hypothesis $n=2$; and let us make likewise $g=\sqrt{3}$ and $p=\sqrt{2}$, as in the primitive rhomboid of calcareous spar. Substituting these values in the expressions for fc and cz (Fig. 13.), we obtain $fc:cz::\sqrt{29}:\sqrt{3}$. This gives 144° 20′ 26″ for the inclination of fpd to bpd. Plate CCXXIV. Fig. 13.

If we substitute the same values in the expressions for de and ek, we obtain $de:ek::\sqrt{5}:\sqrt{3}$. This gives 104° 28′ 40″ for the inclination of fpd to fpq. But this is the angle which measures the inclination of the primitive faces $bafd$, $gafq$, which correspond to the secondary faces fpd and fpq.

Suppose $amhl$ (Fig. 14.) to be the four-sided figure which would be obtained by cutting the rhomboid as (Fig. 7.) by a plane passing through am and perpendicular to $abdf$. Draw ai (Fig. 14.) perpendicular to hm, and corresponding to the line ai (Fig. 7.) Figs. 7, 14.

It is easy to see, that the angle mal (Fig. 14.) measures the inclination of the two faces of the rhomboid taken round the same summit, and consequently it measures that of the rhombs $bofd$, $gofq$ (Fig. 7.) It remains only to prove, that the ratio of mr to ar (Fig. 14.), the sine and cosine of half that angle, is the same as that of de to ek (Fig. 13.)

We have had already am (Fig. 14.) $=\sqrt{\frac{4g^2p^2}{g^2+p^2}}=\sqrt{\frac{24}{5}}=mh$.

We have likewise had

$$ai=\sqrt{\frac{3g^2p^2-g^4}{p^2}}=\sqrt{\frac{9}{2}}.$$

But by construction $ml=2g=\sqrt{12}$. And $ar=\frac{ai\times mh}{ml}=\sqrt{\frac{\frac{9}{2}\times\frac{24}{5}}{12}}=\sqrt{\frac{9}{5}}$. Therefore $mr=g:ar::\sqrt{3}:\sqrt{\frac{9}{5}}::\sqrt{5}:\sqrt{3}::de$ (Fig. 13.) $:ek$, which was the point to be proved.

Let us now compare the solid angle f, formed by the three plane angles pfd, pfq, dfq, with the solid angle a of the nucleus. We have demonstrated, that the inclination of dpf to pfq, is equal to that of $bafd$ to $gafq$. Farther, the angles pfd, pfq are equal, as also the angles baf, gaf. And the angle dfq is equal to the angle bag. Hence the two solid angles are equal in every respect; and since bag is equal to each of the two other angles baf and gaf, it follows, that dfq is equal to each of the angles pfd, pfq. So that not only the inclination of the faces of the secondary crystal, adjacent to the edge pf, is equal to that of the

Mathematical Theory.

corresponding faces of the nucleus, but likewise the obtuse plane angle of the faces of the secondary crystal is equal to that of the faces of the nucleus.

The preceding result furnishes us with a very simple method of obtaining the inclination of any one dpf of the faces of the dodecahedron to the adjacent face below the edge df. For that inclination is equal to that of dpf to $dfqs$ + the difference between this last and that of $bafd$ to $dfqs$. But the inclination of dpf to $dfqs$, is 104° 28′ 40″. That of $bafd$ to $dfqs$, the supplement to the preceding, is 75° 31′ 20″. The difference, of course, is 28° 57′ 20″. Adding this difference to 104° 28′ 40″, we obtain 133° 26′.

Plate CCXXIV. Figs. 13, 15.

Let $bafd$ (Fig. 15.) be the same rhomb as in Fig. 13. Draw by bisecting af. The triangle bay is similar to any one dpf (Fig. 13.) of the triangles of the secondary dodecahedron, so that the sides of the one are double those of the other.

Let us, in the first place, find the value of the three sides of the triangle dpf. We have

1. $df=\sqrt{g^2+p^2}=\sqrt{5}$.

2. dp (which is the same line as in Fig. 12.) $=\sqrt{\left(\frac{2n+1}{3n-3}\right)^2 a^2+\frac{4}{3}g^2}=\sqrt{\frac{25}{9}\cdot 9+4}=\sqrt{29}$.

3. pg (Fig. 12.) $=pg$ or pf (Fig. 13.) $=\sqrt{\left(\frac{n+2}{3n-3}\right)^2 a^2+\frac{4}{3}g^2}=\sqrt{\frac{16}{9}\cdot 9+4}=\sqrt{20}$.

Let us find, in like manner, the value of the three sides of the triangle bay (Fig. 15.)

1. $ay=\frac{1}{2}af=\frac{1}{2}\sqrt{5}=\frac{1}{2}df$ (Fig. 13.)

2. Having drawn ym perpendicular to bf (Fig. 15.), we have

$$by=\sqrt{(bm)^2+(my)^2}=\sqrt{(\tfrac{3}{4}bf)^2+(\tfrac{1}{2}ac)^2}$$
$$=\sqrt{\tfrac{9}{16}\cdot 12+\tfrac{1}{4}\cdot 2}=\tfrac{1}{2}\sqrt{29}=\tfrac{1}{2}dp \text{ (Fig. 13.)}$$

3. ab (Fig. 15.) $=\sqrt{5}=\frac{1}{2}\sqrt{20}=\frac{1}{2}pf$ (Fig. 13.)

We see likewise, that the mean side pf of the triangle dpf is double the small side. All these results take place in the variety of calcareous spar called *metastique* by Hauy.

This variety of crystal gives an opportunity of resolving another problem of considerable importance. It is to determine, from certain data, the ratio of the two semidiagonals g and p of the nucleus, from which the angles of the nucleus and of the secondary crystal may be calculated with rigid accuracy.

Let us employ, as data, the equality observed between the angles pfd and dfq (Fig. 13.), and the law of decrement by two ranges, from which the *metastatic* crystal results, or, if it is preferred, the equality of that part of the axis of the secondary crystal which passes the axis of the nucleus with that of the axis of the nucleus itself. Our object is, from these data, to find the ratio between g and p.

The angle pfd being equal to the angle dfq, or (which is the same thing) to the angle baf, the angles dfk and dfa, which are the supplements to these angles, are likewise equal. Then, since df is equal to af, the sine dk of the angle dfk will be equal to the sine am (Fig. 7.) of the angle dfk (Fig. 13.) But $am=\sqrt{\frac{4g^2p^2}{g^2+p^2}}$.

It remains for us to find dk, in order to form an equation with the value of am.

The triangle dek is rectangular at e; for the plane dfs being perpendicular to the plane afs, is perpendicular also to the plane pfs, which coincides with afs. Therefore, since de is at once situated in the plane dfs and perpendicular to fs, the common section of this plane with the plane pfs, it must be perpendicular likewise to this last plane. Therefore ke, situated in the prolongation of the plane pfs, and which falls upon de, will be perpendicular to this last line. Therefore the triangle dek is rectangular at e. Hence $dk=\sqrt{(de)^2+(ek)^2}$.

But $de=g$, and $ek=\frac{n}{n-1}\sqrt{\frac{\frac{1}{3}a^2g^2}{\left(\frac{n+2}{3n-3}\right)^2a^2+\frac{4}{3}g^2}}$. And because $n=2$, we have

$$ek=2\sqrt{\frac{\frac{1}{3}a^2g^2}{(\frac{4}{3})^2a^2+\frac{4}{3}g^2}}=\sqrt{\frac{3a^2g^2}{4a^2+3g^2}}.$$

Equating the values of the squares of dk and am, we have $\frac{7a^2g^2+3g^4}{4a^2+3g^2}=\frac{4g^2p^2}{g^2+p^2}$.

Substituting for a^2 its value $9p^2-3g^2$, it becomes

$$\frac{7g^2(9p^2-3g^2)+3g^4}{4(9p^2-3g^2)+3g^2}=\frac{4g^2p^2}{g^2+p^2}.$$

By making the two denominators disappear, by reducing and transposing, the expression becomes $g^4-\frac{9}{2}p^2g^2=-\frac{9}{2}p^4$.

This equation gives for the two values of g^2, $g^2=\frac{3}{2}p^2$, and $g^2=3p^2$.

In the first case, $g:p::\sqrt{3}:\sqrt{2}$. This is the ratio wanted between the semidiagonals of the primitive rhomboid. In the second case, we have $g:p::\sqrt{3}:1$. This corresponds with the hypothesis in which the nucleus and secondary crystal would be confounded under the same plane, which would be a regular hexagon.

There is another variety of calcareous spar, called *ascending* by Hauy, because the different laws on which it depends act from below upwards. Among its bounding faces, 12 result from a decrement on the inferior edges, and supposing them prolonged till they cut each other, they would give the form of a dodecahedron similar to the *metastatic*.

Suppose the triangles bpd, dpf, fpq represent three of the superior faces of this dodecahedron. If we measure the incidence of dpf or gpf, we find that it is nearly 101°. This makes us presume, at first, that it is equal to the great angle of the primitive rhomb, namely 101° 32′ 13″. Let us suppose this equality to hold true, and let us determine from thence the decrement, or the value of n.

We have by hypothesis $de:ek::g:p::\sqrt{3}:\sqrt{2}$.

But we formerly obtained

$$de:ek::\sqrt{\left(\frac{n+2}{3n-3}\right)^2a^2+\tfrac{4}{3}g^2}:\sqrt{\left(\frac{n}{n-1}\right)^2\tfrac{1}{3}a^2}.$$

Putting in place of a^2 its value 9, and of g^2 its value 3, we get

$$de:ek::\sqrt{\left(\frac{n+2}{3n-3}\right)^2 9+4}:\sqrt{\left(\frac{n}{n-1}\right)3}::\sqrt{3}:\sqrt{2}.$$

Taking the products of the extremes and means, and suppressing the radical signs, we get

$$\left(\frac{n+2}{3n-3}\right)^2 18+8=\left(\frac{n}{n-1}\right)^2 9;\text{ or,}$$
$$\frac{(n+2)^2 18+(3n-3)^2 8}{(3n-3)^2}=\left(\frac{n}{n-1}\right)^2 9;\text{ or,}$$
$$\frac{(n+2)^2 18+(3n-3)^2 8}{(3)^2}=9n^2.$$

Mathematical Theory.

Getting rid of the denominator $(3)^2$, and developing the quantities $(n+2)^2$, $(3n-3)^2$, and dividing the whole by 9, the expression becomes $(n^2+4n+4)2+(n^2-2n+1)8=9n^2$. Hence we have $n^2-8n+16=0$. Consequently $n-4=0$ and $n=4$. So that the decrement takes place by four ranges.

With respect to the inclination of dpf to dpb, we obtain it by substituting for g, a, n, their values in the expression of the ratio of fc to cz. We will have $fc : cz :: \sqrt{\left(\frac{2n+1}{3n-3}\right)^2 a^2+\frac{4}{3}g^2} : \sqrt{\left(\frac{1}{n-1}\right)^2 \frac{1}{3}a^2} :: \sqrt{39} : \sqrt{3}$. This gives for the inclination sought 161° 48′ 18″.

Another property of this dodecahedron, supposing it complete, is, that the great angle dfp of its faces is a right angle.

To prove this, let us find the value of the three sides df, pf, and dp.

1. $df=\sqrt{g^2+p^2}=\sqrt{5}$.

Plate CCXXIV. Fig. 12, 13.

2. dp (Fig. 12.) $=\sqrt{\left(\frac{2n+1}{3n-3}\right)^2 a^2+\frac{4}{3}g^2}=\sqrt{\frac{81}{81}.9+4}=\sqrt{13}$.

3. pf (Fig. 13.) or its equal $p'g$ (Fig. 12.) $=\sqrt{\left(\frac{n+2}{3n-3}\right)^2 a^2+\frac{4}{3}g^2}=\sqrt{\frac{36}{81}.9+4}=\sqrt{8}$. Therefore (Fig. 13.) $(dp)^2=(pf)^2+(df)^2$. Of course the triangle dfp is rectangular in f.

4. *Decrements on the Lateral Angles.*

Decrements on the lateral angles.

The secondary forms produced by these decrements are usually dodecahedrons, in which three of the edges contiguous to each summit are parallel to the oblique diagonals which correspond to them in the nucleus.

Fig. 16.

Let ti (Fig. 16.) be one of these dodecahedrons, and to one of the edges parallel to the diagonals of the nucleus. Let b be the point of the edge tk which coincides with the lateral solid angle of the nucleus, or which is the point from which the decrement sets out. Let bc be the horizontal semidiameter of the rhomb upon which the same decrements act. Draw be perpendicular to to, and join the points c, e. Let bnm be the measuring triangle; and let g' be the horizontal semidiameter of a molecule. We will have $bn=2ng'$. As for nm, it coincides with the corresponding lateral face of the first plate of superposition, and measures the height of that face. Let as (Fig. 17.) be the nucleus represented separately in a position analogous to that which it has in the interior of the dodecahedron. A little attention will enable us to perceive that the lateral face which has been just mentioned, being contiguous to a range of edges of molecules, parallel to ag and ds, must be itself parallel to the principal section which passes through the points a, d, s, g. And since nm (Fig. 16.) measures the height of that lateral face, it will be equal to the height of a molecule, or to the line ak (Fig. 8.) supposing $adsg$ to represent the principal section of the molecule. Therefore we have

Fig. 17. Fig. 8. Plate CCXXII. Fig. 7.

nm (Fig. 7.) $=\sqrt{\frac{3g'^2p'^2-g'^4}{p'^2}}$. Therefore $bn : nm :: 2gn : \sqrt{\frac{3g^2p^2-g^4}{p^2}} :: 2n : \sqrt{\frac{3p^2-g^2}{p^2}}$, substituting g for g', and p for p', because the dimensions of the molecule are proportional to those of the nucleus.

Let us now obtain the respective inclinations of the faces of the dodecahedron, beginning with that of pto to kto. (Fig. 16.)

It is easy to perceive, that the angle bec is equal to half that inclination, and since the angle bce is a right angle, the two triangles bnm, bce are similar. Hence $bc : ce :: bn : nm :: 2gn : \sqrt{\frac{3g^2p^2-g^4}{p^2}} :: 2n . : \sqrt{\frac{3p^2-g^2}{p^2}}$.

Before calculating the second inclination, or that of otk to rtk, let us determine the portion of the axis of the dodecahedron which exceeds on each side the axis of the nucleus.

Plate CCXXIV. Fig. 18.

Let $adsg$ (Fig. 18.) be the principal section of the nucleus, to an edge of the secondary crystal parallel to the diagonal ad, and io the inferior edge contiguous to the preceding. From the point a, and from c, the centre of ad, draw ax and ce both perpendicular to to.

The similar triangles axt, aks give us $ak : as :: ax=ce : at$.

$$\text{But } ak=\sqrt{\frac{3g^2p^2-g^4}{p^2}}$$
$$as=\sqrt{9p^2-3g^2}.$$

Fig. 16.

ce, being the same line as in Figure 16, we have, $bc=g : ce :: 2gn : \sqrt{\frac{3g^2p^2-g^4}{p^2}}$. Therefore $ce=\frac{1}{2n}\sqrt{\frac{3g^2p^2-g^4}{p^2}}$.

Therefore the proportion becomes $\sqrt{\frac{3g^2p^2-g^4}{p^2}} : \sqrt{9p^2-3g^2} :: \frac{1}{2n}\sqrt{\frac{3g^2p^2-g^4}{p^2}} : at=\frac{1}{2n}\sqrt{9p^2-3g^2}$.

Fig. 19.

Let us suppose a plane oyr (Fig. 16.) perpendicular to the axis. Let oty, rty (Fig. 19.) be the portions of the triangles otk, rtk (Fig. 16.) cut off by this plane. Let tn be the corresponding part of the axis, which we shall suppose equal to tn, (Fig. 18.) Having drawn on, rn, and yn (Fig. 19.), we will have yn equal to gn (Fig. 18.), and on or rn (Fig. 19.) equal to nl (Fig. 18.), or to the prolongation of gn till it meet to.

Draw oz (Fig. 19.) perpendicular to ty, op perpendicular to ny, and join the points z, p. The angle ozp will measure half the inclination of otk (Fig. 16.) to rtk. Let us find expressions for the sine op (Fig. 19.) and the co-sine pz of the angle ozp.

1. For op. Because onp is an angle of 60°, or opn a right angle, $op=on\sqrt{\frac{3}{4}}$. But we must find the value of on or of its equal nl. (Fig. 18.) The similar triangles adr, tln give us $ar : dr :: tn : nl :: at+an : nl$. Or, $\frac{2}{3}\sqrt{a^2} : \sqrt{\frac{4}{3}g^2} :: \left(\frac{1}{2n}+\frac{1}{3}\right)\sqrt{a^2} : nl=\frac{2n+3}{2n}\sqrt{\frac{1}{3}g^2}=on$. Therefore $op=\frac{2n+3}{2n}\sqrt{\frac{1}{3}g^2}\times\sqrt{\frac{3}{4}}=\frac{2n+3}{4n}\sqrt{g^2}$.

2. For pz. The similar triangles tny, pzy (Fig. 19.) give $ty : tn :: py : pz$. Now

$$tn=\left(\frac{1}{2n}+\frac{1}{3}\right)\sqrt{a^2}=\frac{2n+3}{6n}\sqrt{a^2}.$$
$$ty=\sqrt{tn^2+yn^2}=\sqrt{\left(\frac{2n+3}{6n}\right)^2 a^2+\frac{4}{3}g^2}.$$
$$py=yn-pn=yn-\tfrac{1}{2}on=\sqrt{\tfrac{4}{3}g^2}-\frac{2n+3}{4n}\sqrt{\tfrac{1}{3}g^2}=\left(2-\left(\frac{2n+3}{4n}\right)\right)\sqrt{\tfrac{1}{3}g^2}=\frac{6n-3}{4n}\sqrt{\tfrac{1}{3}g^2}.$$

Mathematical Theory.

Hence the above proportion becomes

$$\sqrt{\left(\frac{2n+3}{6n}\right)^2 a^2 + \tfrac{4}{3} g^2} : \frac{2n+3}{6n}\sqrt{a^2} ::$$

$$\frac{6n-3}{4n}\sqrt{\tfrac{1}{3}g^2} : pz$$

$$= \frac{\frac{(2n+3)(6n-3)}{4n.6n}\sqrt{\tfrac{1}{3}a^2g^2}}{\sqrt{\left(\frac{2n+3}{6n}\right)^2 a^2 + \tfrac{4}{3}g^2}}.$$

Now, comparing op with oz, we obtain

$$op:oz::\sqrt{\left(\frac{2n+3}{6n}\right)^2 a^2 + \tfrac{4}{3}g^2} : \frac{2n-1}{2n}\sqrt{\tfrac{4}{3}a^2}.$$

PLATE CCXXIV. Fig. 16. Fig. 19.

Let $g=\sqrt{7}$, $p=\sqrt{3}$, as in the tourmaline; and let us suppose $n=1$, which indicates a decrement by two ranges. We will have, on the one part, bc (Fig. 16.) $:ce::\sqrt{6}:1$; which gives 135° 35′ 4″ for the inclination of pto on kto.

On the other part, we have op (Fig. 19.) $:pz::\sqrt{27}:1$, which gives 158° 12′ 48″ for the inclination of otk to rtk.

As the law of decrements varies, three of the longitudinal edges contiguous to each summit, such as to, tr, (Fig. 16.) preserve the same inclination to the axis, being always parallel to the oblique diagonals of the nucleus, while the three intermediate edges make greater or smaller angles with the axis, by rising up or sinking down. There is therefore a point, when the six edges, being equally inclined to the axis, become equal, so that the solid assumes the form of a dodecahedron composed of two right pyramids, united by their bases. Let us ascertain whether this result can be produced by a regular law of decrement.

Fig. 18.

It is evident that, in this case, gn (Fig. 18.) $= nl$, or $\sqrt{\tfrac{4}{3}g^2} = \frac{2n+3}{2n}\sqrt{\tfrac{1}{3}g^2}$. This equation gives us $n=\tfrac{3}{2}$. That is to say, that the decrement takes place by three ranges. Crystallization furnishes us with an example of this decrement in the faces, which form a kind of ring round the bases of a variety of corundum, called *uniternaire* by Haüy, and in those faces which are situated laterally in pairs in the *binoternary* variety of specular iron ore.

Let us ascertain if there be a case when the dodecahedron having its triangles, two and two, on the same plane, is converted into a rhomboid. At this point, the cosine pz (Fig. 18.) of the angle ozp vanishes. Assuming then the analytical expression for pz, and suppressing its denominator, we have $(2n+3)(6n-3)\sqrt{\tfrac{1}{3}a^2g^2}=0$; or simply, $6n-3=0$. This gives us $n=\tfrac{1}{2}$, which indicates a decrement by a single range of molecules.

Let us now ascertain, in a general manner, the relation between the two semidiagonals g' and p' of the secondary rhomboid.

We have on one side gn (Fig. 18.) $:tn::\sqrt{\tfrac{1}{3}g'^2}:\tfrac{1}{3}\sqrt{9p'^2-3g'^2}::\sqrt{g'^2}:\sqrt{3p'^2-g'^2}$.

On the other side, $gn:tn::\sqrt{\tfrac{4}{3}g^2}:\frac{2n+3}{6n}\sqrt{9p^2-3g^2}$ $=\tfrac{4}{3}\sqrt{9p^2-3g^2}$, because $n=\tfrac{1}{2}$.

Hence $g'^2:3p'^2-g'^2::\tfrac{4}{3}g'^2:\tfrac{4}{3}.\tfrac{4}{3}(9p^2-3g^2)::g^2:12p^2-4g^2$.

Taking the products of the extremes and means, and then reducing, we obtain

$12p^2g'^2-3g^2g'^2=3g^2p'^2$. From which we get this proportion, $g':p'::\sqrt{3g^2}:\sqrt{12p^2-3g^2}::\sqrt{g^2}:\sqrt{4p^2-g^2}$.

In calcareous spar, $g=\sqrt{3}$, $p=\sqrt{2}$. So that in it $g':p'::\sqrt{3}:\sqrt{5}$. That is to say, that the horizontal semidiagonal of the secondary rhomboid, is to the oblique, as the horizontal semidiagonal of the nucleus is to the edge of the same nucleus.

Another property of the secondary rhomboid, which we will consider here, consists in this. The plane angles are equal to the respective inclinations of the faces of the primitive rhomboid, and reciprocally. Farther, the angles of the principal section are the same on one side and the other.

Let us resume the formulæ relative to these three species of angles.

1. For the acute plane angle.

$$r:\text{Cos.}::g^2+p^2:\pm g^2\mp p^2.$$

2. For the smallest inclination of the faces.

$$r:\text{Cos.}::2p^2:\pm g^2\mp p^2.$$

3. For the acute angle of the principal section.

$$\text{Sin.}:\text{Cos.}::\sqrt{3g^2p^2-g^4}:\pm g^2\mp p^2.$$

But if we make $g=\sqrt{3}$, $p=\sqrt{2}$, as in the primitive rhomboid, and take the upper signs in the fourth term of the proportions, the first ratio becomes 5 : 1, the second 4 : 1, and the third 3 : 1.

And if we make $g=\sqrt{3}$, $p=\sqrt{5}$, as in the secondary rhomboid, and take the lower signs in the fourth term of the proportions, the first ratio becomes 4 : 1, the second 5 : 1, and the third 3 : 1. So that the third angles are the same; and with respect to the two others, they are the inverse of each other. This suggested the name *inverse calcareous spar*, by which Hauy has denoted this variety of crystal.

5. Decrements on the Inferior Angle.

Decrements on the inferior angle.

These decrements are analogous to those that take place on the superior angle, both because in general they produce rhomboids, and because they take place both in breadth and in height. In the first case, the faces produced incline towards the superior part of the axis; in the second, they incline the contrary way, or towards the inferior part of the axis. We shall consider, in the first place, the decrements in breadth.

PLATE CCXXIV. Fig. 20.

Let $adsg$ (Fig. 20.) be the principal section of the nucleus, pd the oblique diagonal of the secondary rhomboid, and ud the inferior edge contiguous to that diagonal. The measuring triangle dho will not differ from that which has been already considered in the case of decrements on the inferior edges, (Fig. 12.) We have, in the present case, dh (Fig. 20.) $:oh::2np:\sqrt{g^2=p^2}$. The only difference will be, that the number of diagonals subtracted, which in the preceding case was equal to the number of ranges subtracted, in the present case will only be equal to half that number.

By proceeding in the same way as in the case alluded to, we shall have $ap=\frac{1}{n-1}\sqrt{9p^2-3g^2}$ and $pr=\frac{2n+1}{3n-3}\sqrt{9p^2-3g^2}$.

Let us now ascertain the general expression for the ratio of the two semidiameters g' and p' of the secondary rhomboid.

Let tz be the semiperpendicular to the axis relative to this rhomboid. We shall have

$tz:pz::dr:pr::\sqrt{\tfrac{4}{3}g^2}:\frac{2n+1}{3n-3}\sqrt{9p^2-3g^2}::\sqrt{\tfrac{1}{3}g'^2}:\tfrac{1}{3}\sqrt{9p'^2-3g'^2}$.

Mathematical Theory.

And simplifying

$$4g^2 : \left(\frac{2n+1}{n-1}\right)^2 (3p^2-g^2) :: g'^2 : 3p'^2-g'^2.$$

Taking the products of the extremes and means, getting rid of the denominator $(n-1)^2$, and transposing, we obtain this equation.

$(2n+1)^2 3p^2 g'^2 + (n-1)^2 4g^2 g'^2 - (2n+1)^2 g^2 g'^2 = (n-1)^2 12 g^2 p'^2.$

Developing the quantities $(n-1)^2$, $(2n+1)^2$, and reducing, we get $(2n+1)^2\ p^2 g'^2 + (1-4n) g^2 g'^2 = (n-1)^2 4 g^2 p'^2$, which gives us this proportion,

$$g' : p' :: \sqrt{(n-1)4g^2} : \sqrt{(2n+1)^2 p^2 + (1-4n)g^2}$$

Let $g=\sqrt{3}$, $p=\sqrt{2}$, as in calcareous spar; and let us suppose $n=\frac{1}{2}$. We will get

$$g' : p' :: \sqrt{3} : \sqrt{17}.$$

Such is the ratio of the semidiameters in the variety of calcareous spar called *contrasting* by Hauy.

If in the formula $a\,p = \frac{1}{n-1}\sqrt{9p^2-3g^2}$ we make $n=1$, we get $a\,p = \frac{1}{0}\sqrt{9p^2-3g^2}$, as we did for the decrements on the inferior edges, with this difference, that the vertical faces result from a decrement by two ranges. This case holds in the regular six-sided prism of calcareous spar.

Plate CCXXIV. Fig. 21.

Let us now proceed to the decrements which take place in height on the same angle. Let $o\,u$ (Fig. 21.) be one of the oblique diagonals of the secondary rhomboid, and $o\,p$ the adjacent edge, from which we see that the first of these lines corresponds with the edge $d\,s$ of the nucleus, and the second with the oblique diagonal $a\,d$. Let $d\,h\,e$ be the measuring triangle, in which $d\,h : e\,h :: p : n\sqrt{g^2+p^2}$. Let us, in the first place, find an expression for $a\,p$.

Produce $a\,d$ to l. The triangles $p\,a\,l$, $p\,s\,g$, being similar, we have $g\,s : a\,s + a\,p :: a\,l : a\,p$. But

$$g\,s = 2\,p$$
$$a\,s = \sqrt{9p^2-3g^2}.$$

We must find the value of $a\,l$. The similar triangles $g\,a\,l$, $d\,h\,e$, give us $e\,h : d\,h :: g\,a : a\,l$, or $n\sqrt{g^2+p^2} : p :: \sqrt{g^2+p^2} : a\,l = \frac{p}{n}$.

The above proportion $g\,s : a\,s + a\,p :: a\,l : a\,p$ becomes therefore $2\,p : \sqrt{9p^2-3g^2} + a\,p :: \frac{p}{n} : a\,p$. Hence we have $a\,p = \frac{1}{2n-1}\sqrt{9p^2-3g^2} = u\,s$. From this we may conclude, that $d\,r : u\,r :: \sqrt{\frac{4}{3}g^2} : \left(\frac{1}{2n-1}+\frac{1}{3}\right)\sqrt{9p^2-3g^2} :: \sqrt{\frac{4}{3}g^2} : \left(\frac{2n+2}{6n-3}\right)\sqrt{9p^2-3g^2}.$

Let us ascertain the ratio between the diagonals g' and p' of the secondary rhomboid.

The semiperpendicular on the axis of this rhomboid is to the third of that axis as $d\,r : u\,r$.

Therefore

$$\sqrt{\tfrac{4}{3}g^2} : \frac{2n+2}{6n-3}\sqrt{9p^2-3g^2} :: \sqrt{\tfrac{4}{3}g'^2} : \tfrac{1}{3}\sqrt{9p'^2-g'^2}.$$

Simplifying and getting rid of the radical signs, this proportion becomes $(2n-1)^2\, 4g^2 : (2n+2)^2\ (3p^2-g^2) :: g'^2 : 3p'^2-g'^2$.

Taking the products of the extremes and means, transposing and dividing by two, we get this equation; $(n+1)^2 3p^2 g'^2 + (2n-1)^2 g^2 g'^2 - (n+1)^2 g^2 g'^2 = (2n-1)^2 3 g^2 p'^2.$

Developing the quantities $(2n-1)^2$, $(2n+1)^2$, and reducing

$(n+1)^2 3p^2 g'^2 + (3n^2-6n) g^2 g'^2 = (2n-1)^2 3 g^2 p'^2.$

Hence we obtain this proportion,

$$g' : p' :: \sqrt{(2n-1)^2 3g^2} : \sqrt{(n+1)^2 3p^2 + (3n^2-6n)g^2}.$$

There is a variety of calcareous spar so nearly cubic, that it was distinguished by the epithet. It is not, however, an exact cube, the faces differing about two degrees from being rectangular. Let us see how we may determine the law of decrement which takes place in this variety, knowing the angles of the faces.

The solid being a little more acute than a cube, it follows that the ratio $d\,r : u\,r$, which results from the law that produces it, must be a little greater than that of $1 : \sqrt{2}$ which exists in the cube. It must at the same time be commensurable. But if we substitute successively for the ratio $1 : \sqrt{2}$, the equal ratios $\sqrt{2} : \sqrt{4}$, $\sqrt{3} : \sqrt{6}$, $\sqrt{4} : \sqrt{8}$, we perceive that it is sufficient, in this last expression, to increase the number 8 by unity, changing it into $\sqrt{4} : \sqrt{9}$, to have the commensurable ratio $2 : 3$, which will be a little greater than the former. Let us therefore try this ratio, and suppose $d\,r : u\,r :: 2 : 3$, or

$$\sqrt{\tfrac{4}{3}g^2} : \frac{2n+2}{6n-3}\sqrt{9p^2-3g^2} :: 2 : 3.$$

And because $g=\sqrt{3}$, and $p=\sqrt{2}$, we have

$$2 : \left(\frac{2n+2}{6n-3}\right) 3 :: 2 : 3.$$

From this we obtain $6n-3 = 2n+2$ and $n=\frac{5}{4}$. Therefore, since n expresses the number of ranges subtracted in height, the decrement takes place by 4 ranges in breadth and 5 in height.

Let us ascertain, according to the same hypothesis, the ratio between the semidiameters g' and p'. We have had already

$$g' : p' :: \sqrt{(2n-1)^2 3g^2} : \sqrt{(n+1)^2 3p^2 + (3n^2-6n)g^2}.$$

And making $n=\frac{5}{4}$, $g=\sqrt{3}$, $p=\sqrt{2}$, we have

$$g' : p' :: \sqrt{\tfrac{9}{4}.3.3} : \sqrt{\tfrac{81}{16}.3.2 - \tfrac{45}{16}.3} :: \sqrt{12} : \sqrt{13}.$$

This gives us the smallest inclination of the faces 87° 47′ 45″, which is conformable to observation.

Let us now enquire whether, among all the possible secondary rhomboids, there be one which is similar to the nucleus. In such a case $g' : p' :: g : p$. Substituting the second ratio for the first in the proportion given above, we will have $g : p :: \sqrt{(2n-1)^2 3g^2} : \sqrt{(n+1)^2 3p^2 + (3n^2-6n)g^2}$. From this, getting quit of the radical signs and developing the quantities $(2n-1)^2$, $(n+1)^2$, we obtain

$3n^2p^2 + 6np^2 + 3p^2 + 3n^2g^2 - 6ng^2 = 12n^2p^2 - 12np^2 + 3p^2.$

And reducing, $n^2(3p^2-g^2) = n(6p^2-2g^2)$. This gives us $n=2$. Hence we learn that the result in question may take place in consequence of a decrement by two ranges in height.

If we compare the ratio $d\,r : p\,r$, or $\sqrt{\frac{4}{3}g^2} : \frac{2n+1}{3n-3}\sqrt{9p^2-3g^2}$, with the ratio $d\,r : u\,r$ (Fig. 21.), or $\sqrt{\frac{4}{3}g^2} : \frac{2n+2}{6n-3}\sqrt{9p^2-3g^2}$, ratios the first of which is for decrements in breadth, and the second for decrements in height; we find that they differ only by the quantity, which in the second term multiplies the expression for the axis, and which in the first is $\frac{2n+1}{3n-3}$, and in the second $\frac{2n+2}{6n-3}$. Let us change n in this last expression into n', and let us equate the two, making

Plate CCXXIV. Fig. 21.

Mathematical Theory.

$\frac{2n+1}{3n-3}=\frac{2n'+2}{6n'-3}$. From this equation we get $n=\frac{4n'+1}{4-2n'}$, and $n'=\frac{4n-1}{2n+4}$. Therefore, since the values of n and n' are rational numbers, it follows, that the same form of rhomboid which is possible in consequence of a certain law of decrement in breadth, is possible also by a different decrement in height, and *vice versa*. We may always pass from the one to the other, in consequence of the preceding formulas.

Suppose, for example, we inquire what would be the decrement in breadth which would produce a secondary rhomboid similar to the cuboid. To resolve this question, we have only to take the formula $n=\frac{4n'+1}{4-2n'}$, and make $n'=\frac{5}{4}$. This gives us $n=4$. Hence the law sought would be a decrement by 8 ranges of molecules.

On Intermediate Decrements relative to the Rhomboid.

Intermediate decrements relative to the rhomboid.

The decrements called *intermediate*, depend upon two variable elements which must enter into their calculation. The one is the ratio between the number of lengths of molecules, subtracted from the two sides of the angle on which the decrement takes place. The other is the number of ranges subtracted, or the distance between the same angle and the edge of the first plate of superposition. The fraction $\frac{y}{x}$ represents the ratio between the sides; and n, as usual, denotes the number of ranges subtracted.

In proportion as y diminishes in relation to x, the edge of each plate inclines always more towards the edge of which x constitutes a part, and when y vanishes it coincides with that edge. On the other hand, in proportion as y augments in relation to x, the edge of each plate of superposition becomes more nearly parallel to the diagonal opposite to the angle on which the decrement takes place; and when y becomes equal to x, we have the ordinary decrement on the angles.

Plate CCXXIV. Fig. 22.

Let us consider, in the first place, the effects of an intermediate decrement towards the lateral angles b, u, (Fig. 22.) of any rhomboid, one of the superior faces of which is represented by $a\,b\,d\,u$. Let us suppose $\gamma\lambda$ to be the edge of the first plate of superposition, so that $b\,\gamma$, $b\,\lambda$, measure the respective lengths of molecules on the edges, with this single condition, that $b\,\lambda$ or x is always greater than $b\,\gamma$ or y.

Fig. 23. Fig. 24.

In that case, the secondary solid will be in general a dodecahedron, HX, (Fig. 23.) with triangular faces. Let $a\,g\,s\,d$ (Fig. 24.) be the principal section of the nucleus, and $h\,x$ the axis of the secondary crystal. It is easy to see that of two contiguous edges, such as hq, qx, the first passes though the angle d, while the other is formed at a certain distance above the diagonal $a\,d$. Draw $d\,p$ parallel to this last edge; $d\,p$ will be situated as the oblique diagonal of a rhomboid resulting from a decrement on the angle d, in which the distance of one plate from another, taken in the direction $d\,a$, will be the same as in the dodecahedron that we are now considering. Let dkf be the measuring triangle referred to the plane $p\,d\,r$. kf will represent the length of one molecule. Let us find an expression for $d\,k$.

Draw $\lambda\,\mu$ (Fig. 22.) parallel to $d\,a$; $\gamma\pi$ perpendicular to $\lambda\,\mu$; $d\,\varepsilon$ parallel to $\gamma\,\lambda$; then taking $\varepsilon\,\vartheta$ equal to $b\,\gamma$, draw $\vartheta\,\nu$ parallel to $d\,\varepsilon$, and $\nu\,\varphi$ parallel to $a\,b$. It is evident that $d\,\varepsilon$, $\nu\,\vartheta$ will correspond with the edges of the consecutive plates of superposition; and of course $d\,\nu$ will be the distance of one plate from another, taken in the direction $d\,a$, supposing always only one range subtracted. Therefore we have $d\,\nu \times n = d\,k$ (Fig. 24.). The question is therefore reduced to find an algebraic expression for $d\,\nu$ (Fig. 22.)

Plate CCXXIV. Fig. 22.

But $\lambda\,\mu$ measures as many times the oblique semidiagonal of a molecule, as there are lengths of a molecule contained in $b\,\lambda + b\,\mu = 2\,x$. Therefore denoting by p' the oblique semidiagonal of a molecule, we may represent $\lambda\,\mu$ by $2\,p'x$. On the other side $\omega\,\nu = \varepsilon\,\vartheta = b\,\gamma = y$. But the similar triangles $\omega\,\nu\,d$, $\gamma\,\mu\,\lambda$ give $\gamma\,\mu : \lambda\,\mu :: \omega\,\nu : d\,\nu$; or, $x-y : 2\,p'x :: y : d\,\nu = \frac{2\,p'x\,y}{x-y}$. Therefore $d\,k$ (Fig. 24.) $= \frac{2\,p'\,n\,x\,y}{x-y}$. Therefore, denoting by g' the horizontal semidiagonal of a molecule, we will have $d\,k : k\,f :: \frac{2\,p'n\,x\,y}{x-y} : \sqrt{g'^2+p'^2}$. Or, since the dimensions of the molecule are proportional to those of the nucleus $d\,k : k\,f :: \frac{2\,p\,n\,x\,y}{x-y} : \sqrt{g^2+p^2}$.

Let us now determine the respective incidences of the neighbouring faces towards the same summit of the dodecahedron HX (Fig. 23.), in which the edge QX is conceived to be the same as $q\,x$ (Fig. 24.)

Let us begin with the incidence of CXQ (Fig. 23.) on NXQ. Let $b\,u$ be one of the horizontal diagonals of the nucleus, and $b\,a\,u$, one half of the rhomb to which that diagonal belongs. Let $b\,r$, $u\,y$ be sections of the same rhomb, prolonged for the purpose on the triangles CXQ, NXQ. If we prolong these sections till they meet in a common point m, the triangle $b\,m\,o$ will be similar to the triangle $\gamma\,\lambda\,\pi$ (Fig. 22.), since $b\,m$, $u\,m$ (Fig. 23.), or their parts $b\,r$, $u\,y$, of necessity represent the two decreasing faces of the same plate of superposition.

Draw $b\,n$ perpendicular to QX (Fig. 23). Then join the points o, n. The angle $b\,n\,o$ will be the half of that which measures the incidence of CXQ or NXQ. We must therefore find the relation between the sine $b\,o$ and the cosine $o\,n$ of the angle $b\,n\,o$. But $b\,o = g$. We have only therefore to find $o\,n$.

From the point o (Fig. 24.) in the centre of $a\,d$, and from the point a, draw the lines $o\,n$, $a\,b$ perpendicular to $q\,x$, and produce $g\,a$ till it meets $d\,p$. The line $o\,n$ is the same as $o\,n$ (Fig. 23.). Let us find its algebraic expression.

The triangles $m\,o\,n$, (Fig. 23.) and $d\,o\,z$, (Fig. 24.) are similar, since om (Fig. 23.) coincides with od, (Fig. 24.) $o\,n$ with $o\,z$, and $d\,p$, (Fig. 24.) of which $d\,z$ is a part, is parallel to m X, (Fig. 23.) on which $m\,n$ is situated. Therefore $om : on$ (Fig. 23.) $:: od : oz$ (Fig. 24.) $:: a\,d : a\,l$. Hence to find $o\,n$, we must find $o\,m$, $a\,d$, and $a\,l$. But $a\,d = 2\,p$. We have only therefore to find $o\,m$ and $a\,l$.

1. For $o\,m$. The triangles $\gamma\,\pi\,\lambda$ (Fig. 22.) and $b\,o\,m$ (Fig. 23.) are similar, as has been already observed. Therefore $\gamma\pi : \pi\,\lambda :: bo : om$. But $\pi\,\lambda$ measures as many demidiagonals p as there are lengths contained in $b\,\lambda + b\,\gamma = x+y$; and $\gamma\pi$ measures as many demidiagonals g as there are lengths contained in $\gamma\mu = x-y$. Hence $\gamma\pi : \pi\,\lambda :: gx-gy : px+py :: bo$ (Fig. 23.) $: om :: g : om$. Hence we obtain $o\,m = \frac{p\,x+p\,y}{x-y}$.

2. For $a\,l$ (Fig. 24.). The triangles $a\,l\,p$, $d\,r\,p$ give us $a\,p : a\,l :: d\,p : d\,r$. But $d\,r = \sqrt{\frac{4}{3}\,g^2}$. We have only then to find $a\,p$ and $d\,p$.

Mathematical Theory.

(1.) For ap. The triangles pay, psd give us $ap : ay :: ap+as : ds$. But $as=\sqrt{a^2}$; $ds=\sqrt{g^2+p^2}$. To obtain an expression for ay, we have (from the similar triangles dkf, day) $dk : fk :: da : ay$. Or, $\frac{2pnxy}{x-y} : \sqrt{g^2+p^2} :: 2p : ay=\frac{x-y}{nxy}\sqrt{g^2+p^2}$.

Hence the proportion $ap : ay :: ap+as : ds$ becomes $ap : \frac{x-y}{nxy}\sqrt{g^2+p^2} :: ap+\sqrt{a^2} : \sqrt{g^2+p^2}$.

Hence we obtain $ap=\left(\frac{x-y}{nxy}\right)ap+\frac{x-y}{nxy}\sqrt{a^2}$; and finally, $ap=\frac{x-y}{nxy-x+y}\sqrt{a^2}$.

(2.) For dp. We have $dp=\sqrt{(pr)^2+(dr)^2}$. But $(dr)^2=\frac{4}{3}g^2$. We have only therefore to obtain pr, in order to have an expression for dp.

Now $pr=ap+ar=\left(\frac{x-y}{nxy-x+y}+\frac{2}{3}\right)\sqrt{a^2}=\frac{2nxy+x-y}{3nxy-3x+3y}$.

Therefore $dp=\sqrt{\left(\frac{2nxy+x-y}{3nxy-3x+3y}\right)^2a^2+\frac{4}{3}g^2}$. Of consequence, the proportion $ap : al :: dp : dr$ will become

$$\frac{x-y}{nxy-x+y}\sqrt{a^2} : al :: \sqrt{\left(\frac{2nxy+x-y}{3nxy-3x+3y}\right)^2a^2+\frac{4}{3}g^2} : \sqrt{\frac{4}{3}g^2}.$$

Thus we get $al=\dfrac{\frac{x-y}{nxy-x+y}\sqrt{\frac{4}{3}a^2g^2}}{\sqrt{\left(\frac{2nxy+x-y}{3nxy-3x+3y}\right)^2a^2+\frac{4}{3}g^2}}$.

Resuming the original proportion $om : on :: ad : al$, and substituting the values thus found, the proportion becomes

$$\frac{px+py}{x-y} : on :: 2p : \frac{\frac{x-y}{nxy-x+y}\sqrt{\frac{4}{3}a^2g^2}}{\sqrt{\left(\frac{2nxy+x-y}{3nxy-3x+3y}\right)^2a^2+\frac{4}{3}g^2}}.$$

This proportion gives us

$$on=\frac{\frac{x-y}{nxy-x+y}\sqrt{\frac{1}{3}a^2g^2}}{\sqrt{\left(\frac{2nxy+x-y}{3nxy-3x+3y}\right)^2a^2+\frac{4}{3}g^2}}.$$

Therefore $bo : on :: g :$ *the preceding fraction.* And getting rid of the denominator of that fraction, and dividing by g, we finally obtain $bo : on :: \sqrt{\left(\frac{2nxy+x-y}{3(nxy-x+y)}\right)^2a^2+\frac{4}{3}g^2} : \frac{x+y}{nxy-x+y}\sqrt{\frac{1}{3}a^2} :: \sqrt{\frac{1}{3}(2nxy+x-y)^2a^2+(nxy-x+y^2)4g^2}\,\sqrt{a^2} : (x+y)\sqrt{a^2}$.

Nothing more would be necessary than this ratio, and the law of decrement, to determine the accurate figure of those kind of crystals which we are considering. But an example may be necessary to make the method obvious to beginners.

Let us suppose that HX (Fig. 23.) represents that variety of carbonate of lime called *paradoxal* by Hauy. If we attempt to divide this crystal mechanically, we find that each section, such as $\varepsilon\delta\zeta$, commences from one of the shortest edges, and rises in such a manner that the angle δ contiguous to the edge QX is about 45°.

PLATE CCXXIV. Fig. 23.

This being understood, draw the rhomb $ab\delta u$ (Fig. 25.) similar to the primitive rhomb, and, from the point δ, draw $\delta\varepsilon$, $\delta\zeta$, each of which makes with the diagonal $a\delta$ an angle of $22\frac{1}{2}$°. It is evident that these two lines represent the position of the two decreasing edges of the same plate, so that $b\varepsilon$ and $b\delta$ are to each other as the number of lengths of molecules subtracted from the two sides of the angle on which the decrement takes place. But, on comparing these two lines, we find that $b\delta$ is apparently double of $b\varepsilon$. Hence we conclude, that in the preceding formula $x=2$ and $y=1$. As we are ignorant of the value of n, we give it at first the most simple value, making $n=1$. We know already that $a^2=9$ and $g^2=3$. Substituting these values in the preceding formula, we obtain $bo : on :: \sqrt{29} : \sqrt{27}$. This gives 92° 3′ 10″ for the incidence of CXQ on NXQ. But this measure agreeing with observation, we conclude, that the decrement really takes place by the subtraction of one range of double molecules.

Mathematical Theory. PLATE CCXXIV. Fig. 25.

To determine the incidence of CXB or CXQ, we must have an expression for hr. (Fig. 24.)

But $hr=ux=ax+au=ap+px+au$. Now $ap=\frac{x-y}{nxy-x+y}\sqrt{a^2}$; and $au=\frac{1}{3}\sqrt{a^2}$. We have only therefore to find px.

The similar triangles bax, lap give us $al : bl :: ap : px$. But $bl=nz=on-oz=on-\frac{1}{2}al$. So that the proportion becomes $al : on-\frac{1}{2}al :: ap : px$. But we found formerly, that

$$al=\frac{\frac{x-y}{nxy-x+y}\sqrt{\frac{4}{3}a^2g^2}}{\sqrt{\left(\frac{2nxy+x-y}{3nxy-3x+3y}\right)^2a^2+\frac{4}{3}g^2}} \text{ and}$$

$$on=\frac{\frac{x+y}{nxy-x+y}\sqrt{\frac{1}{3}a^2g^2}}{\sqrt{\left(\frac{2nxy+x-y}{3nxy-3x+3y}\right)^2a^2+\frac{4}{3}g^2}}.$$

From these values we see that al and on are equal, the first to $(x-y)\sqrt{4}$ or to $2x-2y$; the second to $x+y$; multiplied each by the same fraction. We may therefore state the proportion as follows:

$$2x-2y : x+y-x+y :: \frac{x-y}{nxy-x+y}\sqrt{a^2} : px.$$

This gives us $px=\frac{y}{nxy-x+y}\sqrt{a^2}$.

Therefore we have at last

$$hr=\left(\frac{x-y}{nxy-x+y}+\frac{y}{nxy-x+y}+\frac{1}{3}\right)\sqrt{a^2}=\frac{nxy+2x+y}{3(nxy-x+y)}\sqrt{a^2}.$$

Let us now conceive a plane, which, passing through some point of the edge CX (Fig. 23.) is perpendicular to the axis HX. Let qxv, bxv (Fig. 1.) be the two portions of the faces BXC, QXC (Fig. 23.) intercepted by this plane. For the greater simplicity, let us suppose that the plane passes at such a distance from the summit, that the part xr (Fig. 1.) which it intercepts on the axis, is equal to pr (Fig. 24.) In that case, qr (Fig. 1.) or br will be equal to dr (Fig. 24.)

PLATE CCXXV. Fig. 1.

Having drawn pt (Fig. 24.) parallel to qx, produce dr till it meet pt. The line vr (Fig. 1.) will be equal to rt (Fig. 24.)

We have then xr (Fig. 1.) $=\frac{2nxy+x-y}{3nxy-3x+3y}\sqrt{a^2}$

Mathematical Theory.

and $qr=\sqrt{\frac{4}{3}g^2}$. Let us find an expression for vr or its equal rt (Fig. 24.) The similar triangles prt, hrd give $hr:dr::pr:rt$; or $\frac{nxy+2x+y}{3nxy-x+y)}\sqrt{a^2}:\sqrt{\frac{4}{3}g^2}::\frac{2nxy+x-y}{3nxy-x+y)}\sqrt{a^2}:rt=\frac{2nxy+x-y}{nxy+2x+y}\sqrt{\frac{4}{3}g^2}=vr$ (Fig. 1.)

PLATE CCXXIV. Fig. 24.

Join bq; then draw qz perpendicular to vx. Draw also lz. The angle qzl will be the half of that which measures the incidence of qxv on bxv, or of QXC (Fig. 23.) on BXC. But it is easy to have the ratio between ql (Fig. 1.) and lz in values of qr, xr and vr, by a method formerly explained. By that method $ql=\frac{qr}{2}\sqrt{3}$. We obtain lz by means of this proportion $vx:xr::vl:lz$; or $\sqrt{(xr)^2+(vr)^2}:xr::vr-rl:lz::vr-\frac{1}{2}qr:lz$. Hence we get $lz=xr\frac{(vr-\frac{1}{2}qr)}{\sqrt{(xr)^2+(vr)^2}}$.

PLATE CCXXV. Fig. 1.

Hence $ql:lz::\frac{qr}{2}\sqrt{3}:\frac{xr(vr-\frac{1}{2}qr)}{\sqrt{(xr)^2+(vr)^2}}::$

$qr\sqrt{3\left((xr)^2+(vr)^2\right)}:xr(2vr-qr)$. But if we make $g=\sqrt{3}$, $p=\sqrt{2}$, $n=1$, $x=2$, $y=1$, in the algebraic expressions for qr, xr, and vr given above, we get $qr=2$, $xr=5$, $vr=\frac{10}{7}$. Substituting these values, instead of qr, xr, vr, in the ratio of ql to lz, we get $ql:lz::2\sqrt{3\left(25+\frac{100}{49}\right)}:5\left(\frac{20}{7}-2\right)::\sqrt{53}:\sqrt{3}$. This gives us for the incidence of CXB upon CXQ (Fig. 23.) 153° 13′ 58″.

These observations and illustrations will give the reader a pretty accurate idea of the method of proceeding in cases of intermediate decrements. A complete discussion of the subject would swell to a greater length than would be tolerated in a work of this kind. Indeed, we are afraid that we have already extended this Chapter farther than many readers will be disposed to follow us. Those persons who wish to see the intermediate decrements explained at full length, with all the requisite examples, may consult Hauy's *Mineralogie*, vol. i. p. 357. where they will meet with ample satisfaction.

Of the Compound Secondary Forms relative to the Rhomboid.

Compound secondary forms relative to the rhomboid.

The compound secondary forms, especially those which have a rhomboid for a nucleus, are usually nothing else than a combination of several simple forms, which have often a separate existence in particular varieties of the same substance. When the faces belonging to each of these simple forms are sufficiently near each other, and of sufficient size to admit the measurement of their mutual incidences, the compound form may be determined by the calculation of these incidences alone, which is always easy and simple. But it is sometimes necessary, and often useful, to be able to measure the incidences of the faces of one order on those of another order. There are even cases when it becomes interesting to know the plane angles of these faces. To be able to resolve these problems, it is necessary to be accustomed to conceive and to determine the results of the intersections of different planes inclined in different directions. But in the rhomboid we have this advantage, that the determination may be made analytically from the ratios between the quantities which represent the system of lines relative to this kind of solid.

We shall satisfy ourselves with a single example, and we shall select the variety of carbonate of lime called *analogie* by Hauy.

This variety is derived from the *prismatic* carbonate, by its six vertical faces, from the *metastatic* carbonate by its twelve faces, situated six and six on each side of the six vertical faces, and from the *equiaxe* carbonate by its terminal faces, to the number of three at each extremity. These different faces are situated so advantageously, that the knowledge of the angles which the faces of the same order make with each other, (supposing the structure of the forms from which they are derived known) is sufficient to verify the laws upon which the crystal depends. But without any regard to this knowledge, let us endeavour, in the first place, to determine the plane angles of the different faces, and then the incidences of the faces of one order upon those of another.

Let $criz$ (Fig. 2.) be one of the vertical faces, $c\gamma pr$, $c\varepsilon sz$, two of the faces that belong to the metastatic variety, and $\gamma c\varepsilon\mu$ one of the faces derived from the equiaxe. PLATE CCXXV. Fig. 2.

Let dof, qof, duf, quf be four faces of the metastatic variety, supposed complete. Draw the axis ou, the two diagonals ci, rz of the trapezoid $criz$, the great diagonal γr of the trapezoid $c\gamma pr$, and the two diagonals $c\mu$, $\gamma\varepsilon$ of the trapezoid $\gamma c\varepsilon\mu$.

Let us begin with $criz$. The points r, z being situated in the middle of the edges df, qf which are common to the metastatic crystal and to the nucleus, it is obvious that $rz=g=\sqrt{3}$. Of course $rh=\sqrt{\frac{3}{4}}$. Let h (Fig. 3.) be the same point as in (Fig. 2.) If we draw hc (Fig. 3.) parallel to the axis, that line will likewise be the same as the line marked with the same letters in Fig. 2. But the point h (Fig 3.) is situated at $\frac{1}{4}$th the oblique diagonal ft. Hence $fh=\frac{1}{2}p$. But $fh:ft::hc:to$. And $to=2a=6$. So that the proportion becomes $\frac{1}{2}:2::hc:6$. This gives us $hc=\frac{3}{2}$. Therefore (Fig. 2.) $rh:hc::\sqrt{\frac{3}{4}}:\frac{3}{2}::1:\sqrt{3}$. Hence the triangle rcz is equilateral. Fig. 3.

Again, hi (Fig. 3.) is equal to the same line in (Fig. 2.) and from comparing the similar triangles fhi, ftu (Fig. 3.) it appears that $hi=\frac{1}{4}tu=\frac{3}{4}$. Hence hi (Fig. 2.) $=\frac{1}{2}hc$. From these data it follows, that $rcz=60^\circ$, cri or $czi=100^\circ\ 53'\ 37''$, $riz=98^\circ\ 12'\ 46''$.

Let us determine, in the second place, the trapezoid $\gamma c\varepsilon\mu$. Let ou, of, uf, $c\mu$ (Fig. 4.) be the same lines as in Fig. 2. Through the point ζ (Fig. 4.) the same as in Fig. 2.; draw $o\zeta$ (Fig. 4.) and prolong it indefinitely.* This line is evidently in the plane $\gamma o\varepsilon$ (Fig. 2.) or, which comes to the same thing, in the plane doq. Therefore it passes through the middle of the diagonal which joins d, q. Let ϑ (Fig. 4.) be that middle point. Draw $\vartheta\varphi$, $c\sigma$, $\zeta\nu$ perpendicular to the axis, and $\zeta\tau$ perpendicular to $c\sigma$. It may be shewn as follows, that $c\zeta=2\zeta\mu$. Fig. 4.

The similar triangles $c\tau\zeta$, $c\sigma\mu$, give us $c\tau:\tau\sigma::c\zeta:\zeta\mu$. Hence it is clear, that $c\zeta=2\zeta\mu$, provided it can be proved that $c\tau=2\tau\sigma$. For this purpose, let us determine the values of $c\tau$ and $\tau\sigma$.

1. For $c\tau$. $c\tau=c\lambda+\lambda\tau$, and $c\lambda=c\sigma-\sigma\lambda$.

To obtain a value of $\sigma\lambda$, let us observe that the line $\vartheta\varphi$ being the demiperpendicular to the axis in relation

Mathematical Theory.

Plate CCXXV. Fig. 3, 4.

to one of the inferior rhombs of the nucleus, its position is the same as gn (Fig. 3.) Therefore $o\phi$ (Fig. 4.) $= og$ (Fig. 3.) $= oa + ag = 3 + 2 = 5$. Farther, $\vartheta\phi$ (Fig. 4.) $= \sqrt{\frac{1}{3}g^2} = 1$. Now the similar triangles $o\sigma\lambda$, $o\phi\theta$, give $o\sigma : \sigma\lambda :: o\phi : \phi\vartheta :: 5 : 1$.

But we must find the value of $o\sigma$. If from the point c (Fig. 3.) we draw a perpendicular to the axis, it will fall at the extremity a of that axis. For $cf = \frac{1}{4} of$. Therefore, since ca is parallel to fr, the distance ar will be $\frac{1}{4}$ of or. Hence $ar = \frac{1}{3} ao$. From this it follows, that the extremity a of the perpendicular coincides with that of the axis of the nucleus. Since then $c\sigma$ (Fig. 4.) corresponds with ca (Fig. 3.), the point σ (Fig. 4.) is so situated, that $o\sigma$ is the excess of the axis of the metastatic crystal above that of the nucleus. Hence $o\sigma = 3$. Of consequence the proportion $o\sigma : \sigma\lambda :: 5 : 1$ becomes $3 : \sigma\lambda :: 5 : 1$. So that $\sigma\lambda = \frac{3}{5}$.

To obtain a value for $c\sigma$ or its equal ac (Fig. 3.) we have this proportion, $or : fr :: ao : ac$; or $4 : 2 :: 3 : ac = \frac{3}{2} = c\sigma$. Therefore the equation $c\lambda = c\sigma - \sigma\lambda$ becomes $c\lambda = \frac{3}{2} - \frac{3}{5} = \frac{9}{10}$.

We have still to find the value of $\lambda\tau$. The triangles $c\tau\zeta$ and $c\sigma\mu$ give $c\tau : \tau\zeta :: c\sigma : \sigma\mu$; or $c\lambda + \lambda\tau : \tau\zeta :: c\sigma : \sigma\mu$. But $\tau\zeta = 5\lambda\tau$; because these quantities are proportional to $o\sigma = 3$ and $\sigma\lambda = \frac{3}{5}$.

Calling g' and p' the two demidiagonals of the equiaxe, we have $c\sigma : \sigma\mu :: \sqrt{\frac{1}{3} g'^2} : \frac{1}{3}\sqrt{9p'^2 - 3g'^2} :: \sqrt{\frac{1}{3} . 12} : \frac{1}{3}\sqrt{9 . 5 - 3 . 12} :: \sqrt{4} : \sqrt{1} :: 2 : 1$. We have seen already, that $c\lambda = \frac{9}{10}$. Therefore the proportion $c\lambda + \lambda\tau : \tau\zeta :: c\sigma : \sigma\mu$ becomes $\frac{9}{10} + \lambda\tau : 5\lambda\tau :: 2 : 1$. This gives us $\lambda\tau = \frac{1}{10}$.

If we now substitute for $c\lambda$ and $\lambda\tau$ their values thus found in the equation $c\tau = c\lambda + \lambda\tau$, we obtain $c\tau = \frac{9}{10} + \frac{1}{10} = 1$.

2. For $\tau\sigma$. $\tau\sigma = c\sigma - c\lambda - \lambda\tau = \frac{3}{2} - \frac{9}{10} - \frac{1}{10} = \frac{5}{10} = \frac{1}{2}$.

Therefore $c\tau = 2\tau\sigma$. Therefore likewise $c\zeta = 2\zeta\mu$; which was the thing to be proved. Now, since $\zeta\mu$ (Fig. 2.) $: \gamma\zeta :: \sqrt{5} : \sqrt{12}$, we have $c\zeta : \gamma\zeta :: \sqrt{20} : \sqrt{12} :: \sqrt{5} : \sqrt{3}$; which is exactly the ratio of the two demidiagonals of the inverse rhomboid. Hence, of the two triangles $\varepsilon\mu\gamma$, $\varepsilon c\gamma$, the one belongs to the equiaxe, and the other to the inverse variety; and the two heights $c\zeta$, $\mu\zeta$ of these triangles have to each other the same ratio as the heights ch, ih of the triangles which compose the trapezoid $i\gamma$, cz.

Let us now go to the trapezoid $c\gamma pr$, and find, in the first place, expressions for the three sides of the triangle $c\gamma r$.

1. For $c\gamma$. $c\gamma = \sqrt{(c\zeta)^2 + (\gamma\zeta)^2}$ and $c\zeta$ (Fig. 4.) $= \sqrt{(c\tau)^2 + (\tau\zeta)^2} = \sqrt{(c\tau)^2 + (5\lambda\tau)^2} = \sqrt{1 + \frac{25}{100}} = \sqrt{1 + \frac{1}{4}} = \sqrt{\frac{5}{4}}$. Farther, $\gamma\zeta$ (Fig. 2.) $: c\zeta :: \sqrt{3} : \sqrt{5}$. Or $\gamma\zeta : \sqrt{\frac{5}{4}} :: \sqrt{3} : \sqrt{5}$. Of consequence $\gamma\zeta = \sqrt{\frac{3}{4}}$ and $c\gamma = \sqrt{\frac{5}{4} + \frac{3}{4}} = \sqrt{2}$.

2. For cr. $cr = \sqrt{(ch)^2 + (hr)^2} = \sqrt{\frac{9}{4} + \frac{3}{4}} = \sqrt{3}$.

3. For γr. If we conceive a plane perpendicular to the axis to pass through the line $\gamma\varepsilon$, it will cut the axis at a point ν (Fig. 4.) Let us determine the value of $o\nu$. We have $o\nu = o\sigma - \sigma\nu = o\sigma - \tau\zeta = o\sigma - 5\lambda\tau = 3 - \frac{5}{10} = \frac{5}{2}$. But the axis $ou = 9 = \frac{18}{2}$. Therefore the point γ (Fig. 2.) which is at the height of the point ν (Fig. 4.) is situated opposite the $\frac{5}{18}$ of the axis. But the point d (Fig. 2. and 3.) is situated opposite the $\frac{5}{9}$ of the axis, since $og = 5$. Hence it follows, that the point γ (Fig. 2.) is in the middle of the line od. But the point r is in the middle of the line df. Therefore $\gamma r = \frac{1}{2} of = \frac{1}{2}\sqrt{(or)^2 + (fr)^2}$ (Fig. 3.) $= \frac{1}{2}\sqrt{16 + 4} = \sqrt{5}$.

Thus we have found $c\gamma = \sqrt{2}$; $cr = \sqrt{3}$; and $\gamma r = \sqrt{5}$. Hence we are entitled to conclude, 1. That the angle γcr is a right angle; 2. That the triangle $c\gamma r$ is similar and equal to the fourth part of one of the faces of the nucleus divided by the two diagonals.

Having obtained the angle $\gamma cr = 90°$, let us find the angles γpr and $c\gamma p$.

1. For the angle γpr. This angle is the supplement of dpr. But in the triangle rpd, we know $dr = \frac{1}{2} df = \frac{1}{2}\sqrt{5}$. We know $pr = ir = \sqrt{(rh)^2 + (ih)^2} = \sqrt{\frac{3}{4} + \frac{9}{16}} = \frac{1}{4}\sqrt{21}$. Hence $dr : pr :: \sqrt{20} : \sqrt{21}$. The angle pdr, which belongs to one of the faces of the metastatic crystal, is supposed known. Its value is 54° 27′ 30″. From these data we obtain $dpr =$ 52° 34′ 7″. Hence it follows, that $\gamma pr =$ 127° 25′ 53″.

2. For the angle $c\gamma p$. That angle is composed of the two angles $c\gamma r$, $p\gamma r$, the first of which is half the obtuse angle of the primitive rhomb, that is to say, it is equal to 50° 46′ 6″. Now, as $\gamma pr =$ 127° 25′ 53″; as $pr = \frac{1}{4}\sqrt{21}$ and $\gamma r = \sqrt{5}$, it is easy to discover, that $p\gamma r =$ 24° 0′ 24″. Adding this value to that of $c\gamma r$, we obtain $c\gamma p =$ 74° 46′ 30″.

The fourth angle crp must, of course, be equal to 67° 47′ 37″.

We have still to determine the incidence of $c\gamma pr$ upon $czir$, and that of $c\gamma\mu\varepsilon$ on $c\gamma pr$.

Plate CCXXV. Fig. 5.

1. For the incidence of $c\gamma pr$ on $czir$. Let rcz (Fig. 5.) be the same triangle as in Fig. 2. Draw cn (Fig. 5.) situated as cf (Fig. 2.), and produced in such a manner that the lines rn, zn, drawn to its extremity, are perpendicular to it. Draw likewise ch, the height of the triangle rcz, and nh and ng perpendicular to cr, na perpendicular to ch, and lastly ag. The angle nga, which measures the incidence of ncr or crz, is the supplement of that which measures the mutual inclination of the planes $criz$, $c\gamma pr$ (Fig. 2.) Hence the problem is reduced to find the angle nga (Fig. 5.) Let us find, in succession, the value of ng and na.

(1.) For na. On account of the right-angled triangle cnh, $na = \frac{cn \times pn}{ch}$.

$ch = \sqrt{\frac{9}{4}}$; and $rh : hn :: \sqrt{5} : \sqrt{3}$, because the angle rnz measures the smallest inclination of the faces of the metastatic crystal. But $rh = \sqrt{\frac{3}{4}}$, therefore $hn = \sqrt{\frac{3}{4}\cdot\frac{3}{5}} = \sqrt{\frac{9}{20}}$. And $cn = \sqrt{(ch)^2 - (hn)^2} = \sqrt{\frac{9}{4} - \frac{9}{20}} = \sqrt{\frac{9}{5}}$. Hence $na = \frac{\sqrt{\frac{9}{5}} \times \sqrt{\frac{9}{20}}}{\sqrt{\frac{9}{4}}} = \sqrt{\frac{9}{25}}$.

(2.) For ng. $ng = \frac{cn \times nr}{cr}$.

Now we already know that $cn = \sqrt{\frac{9}{5}}$; $nr = \sqrt{(rh)^2 + (hn)^2} = \sqrt{\frac{3}{4} + \frac{9}{20}} = \sqrt{\frac{6}{5}}$; and $cr = \sqrt{(ch)^2 + (rh)^2} = \sqrt{\frac{9}{4} + \frac{3}{4}} = \sqrt{3}$. Hence $ng = \frac{\sqrt{\frac{9}{5}} \times \sqrt{\frac{6}{5}}}{\sqrt{3}} = \sqrt{\frac{18}{25}}$.

Therefore $ng : na :: \sqrt{18} : \sqrt{9} :: \sqrt{2} : \sqrt{1}$. Hence it follows, that $nga = 45°$. Of consequence, the inclination of $c\gamma pr$ to $czir$ is 135°.

Fig. 6.

2. For the incidence $c\gamma\mu\varepsilon$ (Fig. 2.) $c\gamma pr$. Let $\gamma c\varepsilon$ (Fig. 6.) be the same triangle as in Fig. 2. Draw $c\nu$ (Fig. 5.) situated as co (Fig. 6.) and of such a length that the straight lines $\gamma\nu$, $\varepsilon\nu$ (Fig. 6.) drawn to its extremity, are perpendicular to it. Draw likewise $\nu\zeta$ perpendicular to $\gamma\varepsilon$, $\nu\lambda$ perpendicular to $c\zeta$, $\nu\pi$ perpendi-

Mathematical Theory.

cular to $c\zeta$; lastly, draw $\lambda\pi$. The angle $\nu\lambda\pi$ will be the supplement of that which measures the inclination wanted. Let us find $\nu\lambda$ and $\nu\pi$.

PLATE CCXXV. Fig. 6.

(1.) For $\nu\lambda$; $\nu\lambda = \frac{c\nu \times \gamma\nu}{c\gamma}$.

We have already found $c\gamma = \sqrt{2}$. And $c\nu = \sqrt{(c\zeta)^2 + (\zeta\nu)^2}$ and we have found, $c\zeta = \sqrt{\frac{5}{4}}$. Farther, $\gamma\zeta = \sqrt{\frac{3}{4}}$. But $\gamma\zeta : \zeta\nu :: \sqrt{5} : \sqrt{3}$. Hence $\zeta\nu = \sqrt{\frac{9}{20}}$. Therefore $c\nu = \sqrt{\frac{3}{4} + \frac{9}{20}} = \sqrt{\frac{16}{20}} = \sqrt{\frac{4}{5}}$.

$$\gamma\nu = \sqrt{(\gamma\zeta)^2 + (\zeta\nu)^2} = \sqrt{\tfrac{3}{4} + \tfrac{9}{20}} = \sqrt{\tfrac{6}{5}}. \text{ Hence}$$

$$\nu\lambda = \frac{\sqrt{\frac{4}{5} \times \frac{6}{5}}}{\sqrt{2}} = \sqrt{\tfrac{12}{25}}.$$

(2.) For $\nu\pi$; $\nu\pi = \frac{c\nu \times \zeta\nu}{c\zeta}$. And $c\nu = \sqrt{\frac{4}{5}}$; $\zeta\nu = \sqrt{\frac{9}{20}}$; and $c\zeta = \sqrt{\frac{5}{4}}$. Therefore $\nu\pi = \frac{\sqrt{\frac{4}{5} \times \frac{9}{20}}}{\sqrt{\frac{5}{4}}} = \sqrt{\frac{36}{25\ 5}}$.

Hence $\nu\lambda : \nu\pi :: \sqrt{\frac{12}{25}} : \sqrt{\frac{36}{25\ 5}} :: \sqrt{5} : \sqrt{3}$.

Now this is the ratio between the side of the primitive rhomb and half the horizontal diagonal Consequently the angle $\nu\lambda\pi = \frac{101^\circ\ 32'\ 13''}{2} = 50^\circ\ 46'\ 6''$.

Fig. 2. Hence it follows that the incidence of $c\gamma\mu\varepsilon$ (Fig. 2.) on $c\gamma pr$, is $129^\circ\ 13'\ 54''$.

Of the Primitive Forms different from the Parallelopiped.

Primitive forms different from the parallelopiped.

When the primitive form is a cube, the investigation of the secondary crystals admits of certain modifications, which in some cases considerably shorten the calculus. But as there is no new principle in these investigations different from what has been already explained while treating of the rhomboid; we do not consider it as necessary to introduce the peculiar methods here. Those readers who are interested in the subject, will find it amply discussed in Hauy's *Mineralogie*, vol. i. p. 410.

All the other primitive forms, namely, the rhomboidal dodecahedron, the tetrahedron, the octahedron, the six-sided prism, and the bipyramidal dodecahedron, may, by very simple analogies, be brought under the case of parallelopipeds. Indeed we may, without injuring the theory, substitute instead of them a parallelopipedal nucleus, and refer all the decrements to it. The most difficult to manage in that way is the bipyramidal dodecahedron; but it so very seldom occurs in the mineral kingdom as a primitive form, that we do not think it necessary to enter upon the subject here. We again refer the reader to Hauy (*Mineralogie*, vol. i. p. 451.) for all the elucidations necessary to beginners.

Method of determining the ratio between the principal dimensions of the integrant molecules.

On the ratio between the principal dimensions of the integrant molecules.

This is an element in all the calculations respecting secondary crystals; of course, the consideration of it cannot be omitted. Some forms furnish us at once with these ratios, in consequence of the perfect regularity which they appear to possess. For example, we cannot doubt that the form of the integrant molecule of common salt is a cube, and that the primitive crystal of blende is a dodecahedron, with rhomboidal faces equal

and similar; from which it follows, that the integrant molecules are tetrahedrons, having equal and similar triangular faces. From this it follows, that the ratio between the two diagonals of each rhomb is that of $\sqrt{2}$ to 1.

But in certain cases (as when the primitive form is a rhomboid) there is nothing which indicates the size of the angles. In such cases, peculiar methods must be employed to obtain the requisite ratios. Hauy, to whom we are indebted for every thing relating to this subject, has been guided in his investigations by this maxim, that *two quantities are to be considered as equal, when observation points out no difference between them.*

To give an example: When the regular hexahedral prism of carbonate of lime is mechanically divided, we observe, that each section has the same inclination both to the base and to the adjacent face of the prism. If we suppose that this holds rigorously, it is easy to see, that in the rhomboid of calcareous spar, the triangle acn (Fig. 7.), formed by the oblique demi-diagonal ac, by the demi-pendicular cn on the axis, and by an, the third of the axis, is at the same time rectangular and isosceles. Hence it follows, that $cn = an$, or $\sqrt{\frac{1}{3}g^2} = \frac{1}{3}\sqrt{9p^2 - g^2}$. Taking away the radicals, getting rid of the denominators, and simplifying, the equation becomes $g^2 = 3p^2 - g^2$. Hence $2g^2 = 3p^2$ and $g : p :: \sqrt{3} : \sqrt{2}$. PLATE CCXXIV. Fig. 7.

As a second example, we shall make choice of the tourmaline. Crystals of this mineral are known, which have the form represented in Fig. 7. When we measure the inclination of o to l, we find it sensibly the same as that of the edge x to the face P′. But the lateral edges y, y' of the faces o being parallel to each other, and to the oblique diagonal of the primitive face P, it is evident, from simple inspection, that these faces result from the decrement ${}^1E^1$ (Fig. 8.) We see, likewise, that the faces l (Fig. 7.) are produced by a decrement $\overset{2}{e}$. PLATE CCXXV. Fig. 7. Fig. 8.

Let $gads$ (Fig. 18.) be the section of the nucleus of the tourmaline, and tg a line situated as the apotheme of the triangle o (Fig. 7, Plate CCXXV.) It follows, from what has just been stated, that the inclination of o to l is equal to that of tg (Fig. 18.) to a line drawn through the point g parallel to the axis. Or, which is the same thing, it is the supplement of the angle gtn, on the hypothesis that gt is the oblique angle of a rhomboid resulting from the law ${}^1E^1$. Again, the angle formed by x with P′ (Fig. 7.) is equal to the angle gad (Fig. 18.); or, which comes to the same thing, it is the supplement of the angle ags. Hence $gtn = ags$. Therefore $gn : tn ::$ Sin. ags : Cos. ags. Substituting the algebraic values, we get $\sqrt{\frac{4}{3}g^2} : \frac{2n+3}{6n}\sqrt{9p^2 - 3g^2} :: \sqrt{3g^2p^2 - g^4} : g^2 - p^2$. Getting rid of the denominators, and dividing the two first terms by 2, the proportion becomes $\sqrt{g^2} : 2\sqrt{3p^2 - g^2} :: \sqrt{3p^2g^2 - g^4} : g^2 - p^2$. Dividing the two antecedents by g, and multiplying the extremes and means, we get $2(3p^2 - g^2) = g^2 - p^2$. Therefore $7p^2 = 3g^2$, and $g : p :: \sqrt{7} : \sqrt{3}$. PLATE CCXXIV. Fig. 18.

When such analogies are wanting, Hauy arrives at the ratio of the dimensions by adopting the simplest ratio which agrees with the measurement of the inclinations of the faces, and considering it as exact. An example will make the method obvious. Let us make choice of sulphate of iron, the primitive form of which is an acute rhomboid. By the goniometer we find that the smallest inclination of the faces of this rhomboid is nearly $81^\circ\ 30'$. If the ratio between the cosine of this

Crystalline Forms.

angle and radius could be expressed in rational numbers, we would have a simple ratio between g and p. But the logarithm of the sine of 81° 30′ is 9,1697021, which gives for the sine 14781, a number very near 15000. But radius being 100000, we see that the ratio of 15 to 100, or 3 to 20, may be taken without sensible error for the true one. We have then $2p^2 : p^2 - g^2 :: 20 : 3$, or $6p^2 = 20p^2 - 20g^2$, and $10g^2 = 7p^2$. This gives us $g : p :: \sqrt{7} : \sqrt{10}$. According to this hypothesis, the smallest inclination of the faces of the rhomboid is 81° 23′, a quantity which differs only by 7′ from observation. Hence the ratio $\sqrt{7} : \sqrt{10}$ is adopted as the true one.

When all these methods fail, which is often the case, the method adopted by Hauy is this. He supposes the secondary crystals formed by a simple decrement; and from this decrement, and the form of the secondary crystal, the dimensions of the integrant molecules are inferred. We shall not give an example of this method; abundance will be found in the writings of Hauy.

We cannot avoid observing, that this is the weak part of the Hauyan theory. Now that we are in possession of accurate goniometers, it may be greatly improved, and the calculus considerably facilitated. What Hauy has been able to effect, considering the imperfect instruments in his possession, is really surprizing, and does infinite honour both to his industry and sagacity. But it is extremely probable that he is wrong in the dimensions of a great many of the integrant molecules, and of course that the form of the primitive crystal which he assigns, is not perfectly correct. It would be easy to give examples of this supposed inaccuracy; but the task would be invidious. Hauy is at present engaged in printing a new edition of his work; and, as he is now in possession of much better instruments, we may expect considerable ameliorations and improvements.

Chap. III.

Of the Crystalline Forms hitherto observed in the Mineral Kingdom.

Crystalline forms in the mineral kingdom.

This part of our task is attended with considerable difficulty. The different crystals hitherto observed, are too numerous to put it in our power to give figures of the whole, and we are afraid that bare description without figures will scarcely be understood. We shall adopt a middle course. We shall describe particularly only those crystals belonging to each species which we consider as of most importance; and we shall give figures of those only which the young mineralogist ought to make himself familiar with, before he undertakes the general investigation of crystals.

The number of crystals figured by Hauy in his Mineralogy, amounts to about 564. But there would be no difficulty in more than doubling that number. Bournon has figured no fewer than 642 crystals of carbonate of lime; but a considerable number of these are merely simple modifications of the same crystalline form. Hauy has announced, that he will give, in his new edition, the figure of 150 varieties of carbonate of lime. From this statement, the reader will perceive the great extent of the subject, and the consequent difficulties under which we must labour. We shall not think it necessary to notice every species of mineral, but only the most important.

We shall arrange our observations according to the primitive forms of the crystals, beginning with the parallelopiped, which is the most important.

I. Crystals whose primitive Form is the Parallelopiped.

Parallelopiped.

These may conveniently be arranged under ten distinct groups, according to the particular shape of the parallelopiped.

I. *Primitive form a Cube.*

Cube.

To this belong twelve species of minerals; namely,

1. *Common salt.* This species, as far as we have seen it, exists only in three regular forms; 1. The cube; 2. The regular octahedron, formed by a decrement of one range upon each angle; 3. The cubo-octahedron, which is a cube with each of its angles wanting, and a triangular face in their place. It is obviously the second form not completed. Common salt.

2. *Borate of magnesia, or boracite.* Two varieties of the crystals of this species have been observed. 1. A cube with all its edges and four of its angles truncated. This is produced by a decrement of one range upon all the edges, and upon the alternate angles. 2. The same figure as the preceding, with this addition, that the angles left untouched in the first variety, have in this no fewer than four small facets in their place. This is produced by a farther decrement of two ranges upon the alternate angles. Boracite.

3. *Leucite, or amphigene.* This mineral occurs usually in lavas, and, as far as we have seen, is always crystallized in a form nearly spheroidal, having 24 trapezoidal faces. Some notion may be formed of it from inspecting Fig. 9. Leucite. Plate CCXXV. Fig. 9.

4. *Analcime, or cubizite.* This mineral is common in greenstone, and occurs in Salisbury Craigs. We have only seen it crystallized in two forms; 1. A cube, with each angle replaced by three facets. 2. A twenty-four sided figure, bounded by trapezoidal faces, equal and similar. This figure is represented in Fig. 10. It is produced by a decrement of two ranges upon all the angles of the cubic nucleus. The first variety is produced by the same decrement, stopped short before it had completed the trapezoidal faces. Analcime. Fig. 10.

5. *Aplome.* This is a mineral usually crystallized in the rhomboidal dodecahedron. The figure of the garnet is easily distinguished by its inferior specific gravity and lustre. The figure is produced by a decrement of one range on all the edges of the cubic nucleus. Aplome.

6. *Galena, or sulphuret of lead.* The usual figure of this species is the cube; sometimes the octahedron; frequently the cubo-octahedron. The edges and angles of the octahedron are sometimes variously truncated. Galena.

7. *Pyrites, or sulphuret of iron.* Of this there are three species; but one of them, *magnetic pyrites*, may be omitted here. It occurs sometimes in cubes, but is usually amorphous. Hence its crystalline forms are still almost unknown. The other two species are, the *common* pyrites, and the *radiated* pyrites. The first has a cube for its primitive form, the second a right quadrangular prism with a rhombic base, for its primitive form. Hence it belongs to a subsequent group. Pyrites occurs under such a variety of forms, that it would be quite impossible to describe them all here. The two species were long confounded, which occasioned considerable confusion. Bournon pointed out, long ago, the necessity of distinguishing different crys- Pyrites.

Crystalline Forms.

tals of pyrites from each other; and Hauy has lately constituted two species. The first, called *sulphuret of iron*, has a cube for its primitive form. The second, called *white sulphuret of iron*, has a rhomboidal prism for its primitive form, and includes under it all the octahedral crystals of pyrites. If reliance can be put upon the analysis of Hatchett, the composition of these two sulphurets is the same. They therefore constitute an anomaly in the theory of crystallization, similar to that already known in the difference between arragonite and calcareous spar.

Glance cobalt ore.

8. *Glance cobalt ore.* This ore, which occurs in Sweden, is usually crystallized in cubes, or figures derived from it.

Phosphate of manganese-and-iron.

9. *Phosphate of manganese-and-iron,* or pitchy iron ore.

Native gold, silver, and copper.

10, 11, 12. *Native gold, silver, and copper.*

II. *Right quadrangular Prism, base a Square.*

Right quadrangular prism with a square base.

This primitive form, which may be considered as a lengthened cube, belongs to eight species of minerals, namely,

Sulphate of magnesia.

1. *Sulphate of magnesia.* It crystallizes in rectangular prisms, the bases of which are squares. This form is by no means uncommon, though it is more usual to observe the prism terminated by four-sided pyramids, as is represented in Fig. 11.

Plate CCXXV. Fig. 11.

Vesuvian.

2. *Vesuvian or Idocrase.* The primitive form of this substance was at first supposed a cube; but Hauy afterwards determined the real form. It occurs usually in six-sided prisms, terminated by five-sided figures, as represented in Fig. 12. The narrow vertical faces *d*, are produced by a decrement of one range on the vertical edges of the nucleus; the 4 six-sided terminal faces *c, c, c*, by a decrement of two ranges on the angles of the base. The small face P is the remains of the base.

Fig. 12.

Meionite.

3. *Meionite.* This mineral, like the last, occurs in the lava of Mount Vesuvius. The crystals are very small, and are usually eight or twelve sided prisms. The most common variety is represented in Fig. 13.

Fig. 13.

Mesotype.

4. *Mesotype, or radiated zeolite.* This is the mineral originally called *zeolite* by Cronstedt, a name which ought still to be preserved. The most common varieties of its crystals are represented in Fig. 14. and 15.

Figs. 14, 15.

Paranthine and wernerite.

5. *Paranthine or scapolite, and wernerite.* These two minerals seem to belong to the same species. They have been found in Sweden and Norway; and about five different kinds of crystals have been described.

Chromate of lead.

6. *Chromate of lead.* It usually occurs in four-sided prisms, terminated by four-sided pyramids.

Uranmica.

7. *Uranmica,* or green oxide of uranium.

Ruthile.

8. *Ruthile,* or oxide of titanium.

III. *Right quadrangular Prism, with a rectangular Base.*

Right quadrangular prism, with a rectangular base.

This primitive form, like the last, belongs to eight species of minerals.

Cryolite.

1. *Cryolite.* This triple salt is composed of fluoric acid, soda, and alumina, and has been hitherto observed only in Greenland. As far as we know, no regular crystals have yet been observed; but the mineral is foliated, and yields the primitive form by mechanical division.

Anhydrous sulphate of lime.

2. *Anhydrous sulphate of lime.* The crystals of this curious species hitherto observed, have been described by Bournon in the *Jour. de Min.* tom. xiii. p. 346. To this description we refer the reader.

Chrysoberyl.

3. *Chrysoberyl or cymophane.* The most common crystal of this species is represented in Fig. 16. Some new varieties have been described by Hauy in the *Annales du Mus. d'Hist. Natur.* vol. xviii. p. 57.

Plate CCXXV. Fig. 16.

Chrysolite.

4. *Chrysolite or peridot.* The most common crystals of this species are represented in Fig. 17. and 18.

Figs. 17, 18.

Stilbite.

5. *Stilbite, or foliated zeolite.* The crystals of this mineral are usually long, and very beautiful. Fig. 19. represents the variety that perhaps occurs most frequently.

Fig. 19.

Apophyllite.

6. *Apophyllite or ichthyophthalmite.* The crystals belonging to this mineral will be found described by Hauy in the *Jour. de Min.* vol. xxiii. p. 385. One of the crystals described in his mineralogy as belonging to the Stilbite, belongs in fact to this species.

Prehnite.

7. *Prehnite.* This mineral, when it is crystallized, usually assumes the figure of a thin rhomboid, similar to Fig 20.

Fig. 20.

Wolfram.

8. *Wolfram.* The primitive crystal of this species sometimes occurs; but a more common variety is represented in Fig. 21. The faces marked P, M, T, are those of the primitive crystal; the faces *s, s*, are produced by the decrement $A\frac{1}{2}\ \frac{1}{2}A$.

Fig. 21.

IV. *Right quadrangular Prism, Base a Rhomb.*

Right quadrangular prism, base a rhomb.

This primitive form is equally prolific with any of the preceding, belonging to no fewer than twelve species; namely,

Sulphate of barytes.

1. *Sulphate of barytes.* This species, next to calcareous spar, is the most prolific in varieties of crystalline forms. Hauy has announced, that he intends to describe no fewer than 60 of these in the new edition of his Mineralogy. The primitive form occasionally occurs in very small crystals, but by far the most common form, at least in this country, is what Hauy calls the *trapezienne*, represented in Fig. 22. The symbol for which is $\underset{d}{\overset{2}{\mathrm{A}}}\ \underset{o}{\overset{1}{\mathrm{E}}}\ \underset{\mathrm{P}}{\mathrm{P}}$, which will be understood from the letters on the figure.

Fig. 22.

Sulphate of strontian.

2. *Sulphate of strontian.* A considerable number of varieties of these crystals have been observed, almost all in Sicily. We have never seen it assume the primitive form. A common variety is the *unitaire* of Hauy, a kind of wedge-shaped octahedron, represented in Fig. 23; the symbol for which is $\underset{\mathrm{M}}{\mathrm{M}}\ \underset{o}{\overset{1}{\mathrm{E}}}$.

Fig. 23.

Datholite.

3. *Datholite,* or *siliceous borate of lime.* This scarce species has been hitherto found only at Arendal in Norway. The base of its primitive form is a rhomb, with angles of 109° 28′ and 70° 32′; and the height of the prism is to a side of the base as 16 to 15. Only one variety of its crystals has hitherto been described, a kind of ten-sided prism. See *Jour. de Mines*, vol. 19, p. 362.

Granatite.

4. *Granatite* or *staurotide.* It occurs usually in the form of two six-sided prisms crossing each other at right angles, as represented in Fig. 24.

Fig. 24.

Diaspore.

5. *Diaspore.* This singular mineral is a compound of alumina and water; and in this respect agrees with Wavellite. It has not hitherto been found crystallized.

Hyperstene.

6. *Hyperstene* or *labradore hornblende.* This mineral has been lately separated from hornblende, and constituted a species apart by Hauy. It comes from Labradore, and, as far as we know, has not hitherto been observed crystallized.

Mica.

7. *Mica.* The primitive form of this mineral is a prism, with rhomboidal bases, the angles of which are 120° and 60°. It usually occurs crystallized in plates,

Crystalline Forms.

similar to that represented in Fig. 25. The symbol for which is $M\,{}^1H^1\,T\,P$.
$M\ r\ T\ P$

Plate CCXXV. Fig. 25. Talc.

8. *Talc.* The primitive form of this species, and the crystalline forms which it assumes, are exactly the same with those of mica; yet it is necessary to consider them as distinct species, because their composition and external characters differ.

Spodumene.

9. *Spodumene* or *triphane.* This mineral occurs in the mine of Uto in Sweden, and has not hitherto, as far as we know, been observed in crystals.

White-iron pyrites.

10. *White-iron pyrites.* We noticed this species before when speaking of common cubic pyrites.

Arsenical pyrites. Plate CCXXV. Fig. 26.

11. *Arsenical pyrites, or mispickel. Arsenical iron* of Hauy. About six varieties of form of this species are known. One of the most common, (not reckoning the primitive form,) is that represented in Fig. 26, called *ditetrahedre* by Hauy; the symbol for which is $M\,\overset{6}{E}$.
$M\ r$

Molybdena.

12. *Molybdena.* It seldom occurs crystallized. Crystals sometimes occur similar to the crystal of mica, represented in Fig. 25. Schmeifser describes a crystal consisting of a six-sided prism, terminated at both ends by a six-sided pyramid.

Right quadrangular prism, base an oblique parallelogram.

V. *Right quadrangular Prism, Base an oblique Parallelogram.*

This form belongs to three species of minerals. We believe that there is a fourth species ranked by Hauy among prisms with a rectangular base, which really ought to be placed here. The species are:

Gypsum. Fig. 27.

1. *Gypsum*, or *sulphate of lime* The primitive form of this species, is a pretty tall quadrangular prism. The most common variety of its crystals is the *trapezienne* of Hauy, represented in Fig. 27; the symbol for which is $\overset{2}{C}\,\overset{1}{E}\,P$.
$f\ l\ P$

Pistazite. Plate CCXXVI. Figs. 1, 2.

2. *Pistazite*, or *epidote*, and *zoisite.* This is a very common mineral, though it occurs very frequently in an amorphous form. The most common varieties of its crystals which we have been accustomed to see, are represented in Fig. 1, 2. The symbol for the first is $T\,M\,{}^1G^1\,\overset{1}{B}$, the symbol for the second $T\,M\,{}^1G^1\,\overset{1}{C}\,\overset{1}{B}\,\overset{\frac{1}{2}}{E}\,P$.
$T\,M\ r\ z$ $\quad T\,M\ r\ o\ z\ e\ P$

Axinite. Fig. 3.

3. *Axinite*, or *thummerstone.* This mineral is named from the resemblance which its crystals have to the shape of an axe. Though a good many varieties have been described, they all bear a close resemblance to each other. The most common form is represented in Fig. 3. Its symbol is $\overset{2}{C}\,\overset{3}{B}\,\overset{5}{O}\,P$.
$r\ u\ s\ P$

Euclase.

4. We believe that *euclase*, which is described by Hauy as having a rectangular base, has, in fact, an oblique base, and therefore should be placed here. But the mineral is so scarce that it is difficult to examine it.

Oblique quadrangular prism, with a rectangular base.

VI. *Oblique quadrangular Prism, with a rectangular Base.*

Borax.

To this primitive form belongs only one species, namely *borax* or *subborate of soda.* We have never seen any natural specimens of it crystallized with any regularity. But by artificial crystallization it may be obtained under a variety of forms. It usually assumes the form of a six-sided prism.

Crystalline Forms.

Oblique quadrangular prism, base a rhomb.

VII. *Oblique quadrangular Prism, Base a rhomb.*

Glauberite.

To this primitive form belong five species; namely,
1. *Glauberite.* This mineral, hitherto found only in Spain, is composed of nearly equal weights of anhydrous sulphate of lime and anhydrous sulphate of soda. Its base is a rhomb, with angles of 75° 32′ and 104° 28′. Hitherto only one variety of form has been observed. It is an oblique very flat prism, putting one in mind of the common variety of axinite.

Amphibole. Plate CCXXVI. Fig. 4.

2. *Amphibole*, including *hornblende, actinolite, grammatite, tremolite.* This is one of the most abundant mineral species. Hornblende is dark green, almost black; actinolite usually a lighter green; and tremolite almost white. The crystals are usually four or six sided prisms. One of the most common varieties is represented in Fig. 4; the symbol for which is $M\,{}^1G^1\,P\,\overset{\frac{1}{2}}{B}$.
$M\ x\ P\ r$

Augite. Fig. 5.

3. *Augite*, or *pyroxene, coccolite, diopside, salite.* This is also a very common species, occurring abundantly in trap rocks. The crystals are not very numerous in point of variety of form. One of the most common varieties is represented in Fig. 5. The symbol for it is $M\,{}^1H^1\,E^1\,{}^1E$. It is the *bisunitaire* of Hauy.
$M\ r\ \ s$

Gadolinite.

4. *Gadolinite.* Hauy has announced, that the primitive figure of this mineral is an oblique rhomboidal prism. We have never had an opportunity of seeing it crystallized.

Orpiment.

5. *Orpiment*, or *sulphuret of arsenic.* Hauy has lately ascertained, that the primitive form of sulphuret of arsenic, both red and yellow, is the same; namely, an oblique prism with rhomboidal bases, the angles of which are 72° 18′ and 107° 42′. See *Ann. du Mus. d'Hist. Nat.* vol. xvi. p. 19. Hence these two substances, if their composition prove different, will constitute another anomaly in the theory of crystallization.

Oblique quadrangular prism, base an oblique parallelogram.

VIII. *Oblique quadrangular Prism, Base an oblique Parallelogram.*

To this primitive form belong three species of minerals; namely,

Felspar. Fig. 6.

1. *Felspar.* This is perhaps the most abundant mineral in nature. It occurs crystallized in a considerable variety of forms. Perhaps that represented in Fig. 6. is the most useful to be known. Its symbol is $G^2\,T\,P$.
$l\ T\,P$

Cyanite. Fig. 7.

2. *Cyanite*, or *disthene.* This mineral occurs most commonly without any regular crystallization. Four different varieties have been described. One of the most common is represented in Fig. 7.

Sulphate of copper. Fig. 8. Fig. 9.

3. *Sulphate of copper.* A variety of crystalline forms of this salt have been observed; but by far the most common is the primitive form represented in Fig. 8, and the *perihexædre* of Hauy, represented in Fig. 9. Its symbol is $M\,{}^1H^1\,T\,P$.
$M\ n\ T\,P$

Rhomboid with an obtuse summit.

IX. *Rhomboid with an obtuse Summit.*

To this primitive form belong eight species of minerals; namely,

Carbonate of lime.

1. *Carbonate of lime*, or *calcareous spar.* The angle at the summit is 105° 5′. This is the most prolific of all known minerals in the variety of forms. The following are the most common varieties:—1. The *equiaxe*,

4

Crystalline Forms.

Plate CCXXVI. Fig. 10. Fig. 11. Fig. 12. Fig. 13. Fig. 14.

represented in Fig. 10. Its symbol is $\overset{1}{B}$. 2. The *inverse*, represented in Fig. 11. Its symbol is $E^1\,{}^1E$.

$g \quad f$

3. The *metastatic*, represented in Fig. 12. Its symbol is $\overset{2}{D}$. 4. The *contrasting*, represented in Fig. 13. Its symbol is $\overset{3}{c}$. 5. The regular six sided prism, represented in Fig. 14. Its symbol is $\overset{2}{e}\,A$. The equiaxe,

$r \quad m \quad c\ o$

with a very small prism interposed, is called *dog tooth spar*.

Bitter spar.

2. *Bitter spar*, or *magnesian carbonate of lime*. It was supposed formerly to have the same primitive form as calcareous spar. But Dr Wollaston has discovered, that the angle at the summit is 106° 15′.

Carbonate of iron.

3. *Carbonate of iron*, or *flosferri*. It was supposed to have the same primitive form with calcareous spar; but Dr Wollaston has discovered, that the angle at the summit is 107°.

Quartz.

4. *Quartz*. This is a very abundant mineral. The primitive form is a rhomboid, with angles of 94° 4′ and 85° 56′, and therefore differing but little from a cube. This primitive form is uncommon; but Mr Philips of London has specimens of quartz crystallized in this form. They are small; but very distinct. By far the most common variety of its crystals is that repre-

Fig. 15.

sented in Fig. 15. The symbol for which is $\overset{2}{e}\,P\,\overset{\frac{1}{2}}{e}$.

$r\ P\ z$

The terminating pyramids are usually less regular in the size of the faces than is represented in the Figure.

Tourmaline. Fig. 16.

5. *Tourmaline* or *schorl*. The angle at the summit is 113° 34′ 31″. It usually occurs in nine sided prisms. A common variety is represented in Fig. 16. Its symbol is $\overset{1}{D}\,\overset{2}{E}\,\overset{2.0}{e}\,P\,{}^1E^{1\;0.1}\,e^{1.0}$.

$s\ l\ \ P\ o$

Dioptase.

6. *Dioptase*, or *copper emerald*. This mineral comes from Siberia, and is still scarce. But few crystalline forms of it have been observed.

Chabasie.

7. *Chabasie*, sometimes called *cubic zeolite*. It occurs in trap rocks. The angle at the summit is 93° 30′, so that it does not differ much from a cube.

Red silver ore.

8. *Red silver ore, antimoniated sulphuret of silver*. Hauy at first conceived, that the primitive form of this ore was the rhomboidal dodecahedron. But he afterwards ascertained, that it was a rhomboid. The crystalline forms are pretty numerous. But as the one is easily distinguished by its colour and other properties, we need not give figures here.

Rhomboid with an acute summit.

X. *Rhomboid with an acute Summit.*

To this primitive form belong three species of minerals; namely,

Corundum.

1. *Corundum*. This is the name given by mineralogists to the *sapphyr, oriental ruby, corundum, adamantine spar*, and *emery*, which have been shewn by Bournon to belong all to the same species, and to have the same primitive form.

The best description of its crystals was published by Count Bournon in the *Philosophical Transactions*. It occurs in six sided prisms, and in dodecahedrons formed by two six sided pyramids applied base to base.

Oligiste iron ore.

2. *Oligiste iron ore*, or *glance iron ore*. The primitive form does not differ much from a cube, the angles of the rhombs being 87° and 93°. One of the most common varieties of its crystals is represented in Fig. 17. Its symbol is $P\,E^3\,{}^3E\,A$.

$P\ \ n\ \ \overset{2}{s}$

Plate CCXXVI. Fig. 17. Sulphate of iron.

3. *Sulphate of iron*. The angles of the rhomboidal faces are 79° 50′ and 100° 10′. It occurs as commonly in its primitive form as in any other.

Tetrahedron.

II. Crystals whose Primitive form is the Tetrahedron.

Only two species of minerals belong to this class, and both occur among the copper ores; namely,

Copper pyrites; Grey copper ore.

1. *Copper pyrites*; 2. *Grey copper ore*, or *fahlore* and *graugiltigerz*. These two have the same crystalline forms, namely, modifications of the tetrahedron, and probably ought to constitute but one species. The first consists of copper, iron, and sulphur; the second, of copper, iron, arsenic, and sulphur; while the graugiltigerz is composed of copper, iron, antimony, and sulphur. If the arsenic and antimony were mechanical mixtures, then the constituents of all would be the same.

Hexagonal Prism.

III. Crystals whose Primitive form is a Hexagonal Prism.

This crystalline form belongs to eight species of minerals; namely,

Apatite. Fig. 18.

1. *Apatite* or *phosphate of lime*. It occurs often crystallized in the primitive form which is represented in Fig. 18. Most of the varieties bear so close a resemblance or connection with the primitive form, that they may be easily traced to it with the eye.

Carbonate of strontian.

2. *Carbonate of strontian*. It seldom occurs crystallized. The only crystallized specimens of it that we have seen had the primitive form.

Emerald.

3. *Emerald*. This mineral occurs frequently in the primitive form. Indeed all the crystals of it that we have seen are slight modifications of that form. We suspect some of the varieties figured by Hauy as belonging to the euclase, are emeralds.

Nepheline. Fig. 19.

4. *Nepheline* or *sommite*. It occurs often in the primitive form. A common variety is given in Fig. 19. The symbol for which is $M\,\overset{1}{B}\,P$.

$M\ r\ P$

Pinite.

5. *Pinite* or *micarell*. Has considerable resemblance to mica in appearance. We have only seen it crystallized in the primitive form.

Dipyre.

6. *Dipyre*. Two different varieties of crystals belonging to this species have been announced by Hauy. We have not seen them, and cannot therefore describe them.

Sulphurate of copper.

7. *Sulphurate of copper* or *glance copper ore*. As far as we have seen, the crystals of this species are always primitive.

Cinnabar.

8. *Cinnabar*, or *sulphuret of mercury*. It occurs also usually in the primitive form. Only one other variety is described by Hauy.

The reader will observe, that those species which have the six sided prism for a primitive form, occur usually crystallized in that form. The same observation applies to the cube, the tetrahedron, the rhomboidal dodecahedron, and the regular octahedron. But it does not apply to the other primitive forms.

Rhomboidal Dodecahedron.

IV. Crystals whose Primitive form is the Rhomboidal Dodecahedron.

This primitive form belongs only to two species of minerals. The inclination of the faces to each other is obviously 120°.

Crystalline Forms.

Garnet. Plate CCXXVI. Fig. 20.

1. *Garnet.* This species occurs most commonly in the primitive form. We have seen it likewise crystallized, as in Fig. 20. The symbol for which is $\underset{n}{\underset{1}{\overset{r}{B}}}$.

Blende.

2. *Blende.* It occurs crystallized in its primitive form. Likewise in tetrahedrons and octahedrons. And in some other forms which are modifications of these.

Bipyramidal Dodecahedron.

V. Crystals whose Primitive Form is the Bipyramidal Dodecahedron.

Only two mineral species have this primitive form, and they are both salts; namely,

Carbonate of barytes.

1. *Carbonate of barytes.* The crystals of this species are small and rare. Hence its primitive form remained long indetermined. It was first supposed by Hauy to be a six-sided prism. We have seen it crystallized in the primitive form in Scotland. The specimen, we believe, was found at Wanlock-head, but we are not certain.

Phosphate of lead.

2. *Phosphate of lead.* We have seen specimens of the primitive form of this mineral from Cornwall. But it is more commonly crystallized in six-sided prisms.

Octahedron.

VI. Crystals whose Primitive Form is the Octahedron.

This primitive form, next to the parallelopiped, is the most extensive in the mineral kingdom. The crystals belonging to it may be conveniently distributed into four groups, according to the shape of the octahedron.

Regular octahedron.

I. *Regular Octahedron.*

This primitive form belongs to eleven species of minerals; namely,

Salammoniac.

1. *Salammoniac.* This mineral, as far as we know, has never been observed crystallized in a native state. But by artificial crystallization, it has been obtained in regular octahedrons, in cubes, and in a figure bounded by twenty-four trapezoids, somewhat like the leucite crystal.

Fluor spar.

2. *Fluate of lime, Fluor spar.* This mineral occurs usually crystallized in cubes; though we have seen specimens of it crystallized in the primitive form.

Alum.

3. *Alum.* This salt almost always occurs in octahedrons. Sometimes it takes the cubic form, but very rarely. The cubo-octahedron also sometimes occurs.

Spinell.

4. *Spinell,* including *Ceylanite* and *Automalite.* This mineral likewise almost always has the primitive form. Sometimes the edges are truncated in consequence of a decrement of one range parallel to the edges.

Diamond.

5. *Diamond.* This mineral assumes a considerable number of crystalline forms; we have seen at least 30; but no description of them has yet been published. It occurs often in octahedrons, and often likewise with 48 spherical faces, as represented in Fig. 21.

Fig. 21. Native amalgam.

6. *Native amalgam.* This rare mineral occurs usually in regular octahedrons It is said that it has been observed likewise crystallized in rhomboidal dodecahedrons.

Red copper ore.

7. *Red copper ore,* or *Protoxide of copper.* It is most commonly crystallized in octahedrons, sometimes in cubes, sometimes in cubo-octahedrons.

Magnetic iron ore.

8. *Magnetic iron ore,* or *Deutoxide of iron.* The crystals of this mineral are usually octahedrons; sometimes it occurs in rhomboidal dodecahedrons.

White oxide of arsenic.

9. *White oxide of arsenic.* The only crystals of this mineral hitherto observed, are regular octahedrons.

Native bismuth.

10. *Native bismuth.* Hauy has ascertained, by mechanical division, that the regular octahedron is the primitive form of this species. It has been observed in regular crystals of three forms: 1. Regular octahedron. 2. Cube. 3. Rhomboid, with angles of 60° and 120°. See Hauy, *Ann. du Mus. d'Hist. Naturelle,* tom. xii. p. 198.

Native antimony.

11. *Native antimony.* We have seen specimens of this mineral from the mine of Salu in Sweden. But it is very scarce. We do not know that it has ever been observed crystallized. But Hauy has ascertained its primitive form by mechanical division.

Pyramids having a rectangular base.

II. *Pyramids having a rectangular Base.*

This primitive form belongs to 12 species of minerals; namely,

Nitrate of potash.

1. *Nitrate of potash.* This salt sometimes occurs crystallized in its primitive form, but much more commonly in six-sided prisms, often terminated by six-sided pyramids.

Sulphate of soda.

2. *Sulphate of soda.* This salt occurs crystallized in a good many forms. Romé de Lisle gives the fullest and best account of its crystals that we have seen. The common crystals are in four or six-sided prisms, and so much channelled and irregular, that it is scarcely possible to determine their angles.

Lomonite.

3. *Lomonite.* But few crystallized specimens of this mineral have been hitherto observed. Hauy has determined its primitive form, and described some of its varieties in his *Tableau Comparatif,* p. 49, and 195, to which we refer the reader.

Chiastolite.

4. *Chiastolite,* or *Hollowspar*; *Macle* of Hauy. Werner considers this mineral as a sub-species of felspar. But Hauy has ascertained that its primitive form is the octahedron. It occurs usually in four-sided prisms.

Arragonite.

5. *Arragonite.* This species has long puzzled the Abbé Hauy. Its constituents are the same as those of calcareous spar, but its properties are different. He has at last put it into his system as a peculiar species. The fullest description of its crystals is given by Bournon in his *Mineralogie,* to which we refer.

Topaz.

6. *Topaz.* Hauy at first conceived the primitive form of the topaz to be a parallelopiped, consisting of a right prism, with rhomboidal bases. But he afterwards ascertained that it is an octahedron, and the same with that of *shorlous beryl,* to which he has in consequence united it. It occurs most frequently in eight-sided prisms, similar to Fig. 22.

Plate CCXXVI. Fig. 22. Yenite.

7. *Yenite.* This very scarce mineral has been hitherto found only in the Isle of Elba. Hauy, in his *Tableau Comparatif,* has announced the octahedron as its primitive form; and Cordier, the discoverer of the mineral, has described five varieties of crystal in the *Jour. des Min.* vol. xxi. p. 65.

Carbonate of lead.

8. *Carbonate of lead.* This mineral occurs crystal lized in octahedrons, and likewise in bipyramidal dodecahedrons, and six-sided prisms.

Sulphate of lead.

9. *Sulphate of lead.* The most common form of the crystals of this salt is the octahedron, though it occurs also crystallized in various other very irregular forms.

Muriate of copper.

10. *Muriate of copper.* This salt was brought originally from South America. It has been observed also in the lava of Mount Vesuvius. The primitive form is the octahedron, and three varieties of crystals have been described.

Arseniate of copper.

11. *Arseniate of copper.* This mineral, found first

Crystalline Forms.

in Cornwall, has been described by Bournon in the *Philosophical Transactions.* Hauy has reduced all his species under the common laws of decrement.

Calamine.

12. *Calamine.* This mineral occurs but rarely crystallised. Hauy, however, in his *Mineralogie,* has described three varieties of form. The most common is that represented in Fig. 23.

Plate CCXXVI. Fig. 23.

III. *Pyramids having a Square Base.*

Pyramids having a square base. Mellite.

To this primitive form belong seven species of minerals; namely,

1. *Mellite,* or *Honeystone.* This singular mineral occurs crystallized in the primitive form, and in dodecahedrons differing about one degree in the inclination of the faces from the common rhomboidal dodecahedron.

Zircon.

2. *Zircon,* including the *Hyacinth.* It occurs in the primitive form, also in various other forms. The most usual are represented in Figs. 24. and 25. The symbol for the first is $\underset{s}{{}^{1}E^{1}}\;\underset{P}{P}$; for the second $\underset{l}{\underset{1}{\overset{1}{D}}}\;\underset{P}{P}$. The first is the most common form of hyacinth, the second of the jargon of Ceylon.

Figs. 24, 25.

Harmotome. Fig. 26.

3. *Harmotome, cross stone,* or *staurolite.* The most common variety of the crystals of this species is represented in Fig. 26. Its symbol $\underset{o}{{}^{1}E^{1}}\;\underset{P}{P}$.

Oxide of tin.

4. *Oxide of tin, tinstone.* Hauy at first supposed the primitive form of this species to be the cube, but he has more recently found it to be an octahedron. The crystals of this species are numerous. By far the most accurate description of them has been drawn up by Mr Philips, and will be probably published in the second volume of the *Transactions of the Geological Society of London.*

Molybdate of lead. Figs. 27, 28.

5. *Molybdate of lead.* The crystals of this species have most commonly the forms represented in Figs. 27. and 28. The symbol for the first is $\underset{h}{\overset{1}{D}}\;\underset{g}{\overset{1}{A}}$; for the second $\underset{h}{\overset{1}{D}}\;\underset{l}{{}^{1}E^{1}}\;\underset{\overset{1}{g}}{A}$.

Anatose. Plate CCXXVI. Fig. 29.

6. *Anatose* or *octahedrite.* This species consists of pure oxide of titanium; yet its crystalline form is essentially distinct from the titanite. Besides the primitive, it occurs in various forms; one of the most common of which is represented in Fig. 29. The symbol for it is $\underset{P}{P}\;\underset{\overset{3/4}{r}}{A}$. The crystals of this species are always very small.

Tungstate of lime.

7. *Tungstate of lime.* Hauy at first supposed that the primitive form of this species was the cube, but he afterwards found it to be the octahedron. It occurs usually crystallized in octahedrons.

IV. *Pyramids having a Rhomb for their Base.*

Pyramids having a rhomb for their base.

There are four species of minerals that belong to this primitive form, namely,

Carbonate of soda. Fig. 30.

1. *Carbonate of soda.* The primitive form of this species is represented in Fig. 30. The angle which the edge D makes with D′ is 120°, and the inclination of the face P to P′ is 74°. The most common crystalline form of this salt is exhibited in Fig. 31. Its symbol is $\underset{P}{P}\;\underset{\overset{1}{o}}{A}$.

Fig. 31.

Sulphur.

2. *Sulphur.* Very splendid crystals of this mineral have been brought from Spain and Sicily. It occurs in the primitive form, often lengthened edgewise, and sometimes the points of the pyramids are truncated. We give no figures, because there never can be any difficulty in distinguishing the species.

Blue carbonate of copper.

3. *Blue carbonate of copper, hydrate of copper.* This species occurs crystallized, but the crystals are so small that it is scarce possible to determine their form with accuracy. Hauy has followed Romé de Lisle, who obtained his crystals by evaporating an ammoniacal solution of copper.

Sphene.

4. *Sphene* and *titane siliceo-calcaire* of Hauy. This mineral occurs frequently in rhomboids, with their alternate angles truncated. We want still a good description of the crystalline forms which it assumes. Hauy will doubtless supply the deficiency when his new edition makes its appearance. (c)

C U B

Cuba.

CUBA, one of the largest of the West India Islands, stretches from east to west from the seventy-fourth to the eighty-fifth degree of west longitude, and lies between the parallels of 19° 56′ and 23° 18′ of north latitude. Its greatest length, from Cape Maize on the east to Cape St Antonio on the west, is 764 British miles; its greatest breadth at Cape de Cruz is 133 miles, and its least breadth 74 miles. It is about 62 miles to the west of St Domingo, 168 miles to the east of Yucatan, 96 to the north of Jamaica, and 130 to the south of Florida.

A long chain of mountains extends from east to west along the whole length of the island, and divides it into two parts. About 158 rivers and brooks have their origin in this range, and carry down with the detritus of the mountains a very fine gold, which affords reason to believe that there are mines of this metal in the interior. At the foot of these mountains are large tracts of meadow ground, called Savannas, which feed an immense number of cattle, both wild and tame, the skins of which form one of the principal articles of the commerce of the island. The skins are reckoned superior to any of those from other parts of the West Indies, and are known in Europe by the name of the skins of the Havannah, the town from which they are exported. About 10,000 or 12,000 skins were annually sent from the island.

The mountains abound in large timber, particularly the cedar and acajou, caobas, oaks, granadillos, guayacanes, and ebony trees. The fertility of the soil is great. The most delicate herbs and fruits are in full blossom the whole year round, the fields are constantly covered with flowers, and the trees never lose their foliage. Two crops are often produced annually from some of the seeds, one of the crops coming to maturity in the middle of winter. The temperature of the island is very warm and dry, and, owing to the refreshing gales from the north and east, it is more mild than that of the island of St Domingo. A great deal of rain falls in the months of July and August; but the other months of the year are hot and dry.

The principal productions of Cuba are sugar, coffee, tobacco, wax, ginger, long pepper, and other spices, mastic, aloes, vanilla, cassia, fistula, manioc, maize, cocoa, &c. The sugar cane was introduced into Cuba from St Domingo, and has been cultivated here with such success, that no fewer than 480 sugar engines have been erected. In the year 1803, there were exported from the Havannah 158,000 caxas (or chests), of 16 arrobas, or 200 kilogrammes; and from the Port of the Trinity and Santiago de Cuba, including the contraband, 3000 caxas: so that the total exportation of sugar from Cuba, in 1803, was 37,600,000 kilogrammes. The average amount of the export of sugar from the Havannah, from 1801 to 1810 inclusive, has been 2,850,000 arrobas, or about 644,000 cwt. *per annum.* The consumption of sugar in the island amounts to from 25,000 to 30,000 caxas. When M. Humboldt visited this island, he found, from the most exact calculations he could make, that a given hectare of ground yields, at an average, 12 cubic metres of *vezou*, from which is drawn by the processes hitherto in use, in which much saccharine matter is decomposed by fire, at the utmost from 10 to 12 *per cent.* or 1500 kilogrammes (3310 pounds avoirdupois) of raw sugar. At the Havannah, they reckon that a caballeria of ground, which contains 18 square *cordeles* (at 24 varas), or 133,517 square metres (1,437,163 square feet), yields *per annum* 2000 arrobas, or 25,000 kilogrammes (upwards of 50,000 pounds avoirdupois). The average produce is, however, only 1500 arrobas, or 1400 kilogrammes (3089 pound avoirdupois) per hectare (107,639 square feet.)

The establishment of a great sugar plantation in Cuba, wrought by 300 negroes, and producing 500,000 kilogrammes (1,103,500 pounds avoirdupois) of sugar, annually requires an advance of L.83,340 sterling, and brings in from L.12,500 to L.14,600 sterling. Two hundred negroes are required to produce 250,000 kilogrammes of raw sugar; and the purchase of these negroes amounts to L.12,500 sterling. The maintenance of a slave amounts to more than 16s. 8d. per month.

The tobacco manufactured in the island of Cuba is of most excellent quality; and though the cultivation of this article has of late years suffered a considerable diminution, yet it forms one of the chief branches of the royal revenue. It is exported to Europe in the form of leaf, snuff, and cigars; and is deemed superior to the tobacco from any other part of America. The best comes from the town of Trinity and from Santi Espiritus; and it is from this that the European Spaniards manufacture the celebrated tobacco of Seville. The preference given to the cultivation of coffee, and the vexations which the planters experience, have greatly reduced the produce of the tobacco farms in Cuba. In 1803, the island scarcely supplied 150,000 arrobas, whereas, in good years, before 1794, the crop was estimated at 315,000 arrobas (7,873,000 pounds*), of which 128,000 arrobas were exported to Spain, and 160,000 consumed in the island. About 56,000 pounds are annually sent to New Spain.

After the destruction of the coffee plantations in St Domingo, coffee began to be cultivated in the island of Cuba; and in the year 1804 it produced about 12,000 quintals. Bees were introduced into the island in 1763 by some emigrants from Florida; and such was the rapidity with which they multiplied in the hollows of old trees, that there was soon sufficient wax for the annual consumption. In 1777, 715,000 pounds were exported from the Havannah, of a quality equal to the wax of Venice. Including the contraband, Cuba exported, in 1803, 42,670 arrobas of wax, the price of which was then from 20 to 21 piastres per arroba; but the average price, in time of peace, is only 15 piastres, or L.3, 2s. 6d. sterling. A small part of this wax is produced by the wild *trigones*, which occupy the trunks of the *cedrela odorata*; but the principal part is the produce of the common bee.

When Cuba was first conquered by the Spaniards, a considerable quantity of gold was found in the parts now called Jagua and the city of Trinidad; and Herrera affirms that it was more pure than that of St Domingo. A small quantity is found at present at Holguin. An assiento of the mine was established here under the reign of King Don Juan de Eguiluz, when no less than 1000 quintals of gold were sent annually to Spain. There are in Cuba mines of copper and loadstone; and in the jurisdiction of the Havannah an iron mine of excellent quality has been lately discovered. Artillery, similar to that which was in the fortified places of the Havannah, Cuba, and the castle of Morro, were formerly cast here. On the road from Bayamo to Cuba are found pebbles of various sizes, and so perfectly round, that they might be used for cannon balls. There are numerous warm baths in the island, and great numbers of salt ponds. It contains also 982 herds of large cattle, 617 inclosures for fattening swine, 350 folds for fattening animals, 1881 manufactories, and 5933 cultivated estates.

The whole island is divided into two governments, viz. that of Cuba and the Havannah, which are again subdivided into jurisdictions and districts. The governor of the Havannah is captain-general of the whole island, and extended his authority as far as the provinces of Louisiana and Movila. The whole island was one diocese suffragan to the archbishopric of St Domingo; and its jurisdiction comprehended the provinces of Louisiana, and had the title of those of Florida and Jamaica. It contained 21 parishes, 90 churches, 52 curacies, 23 convents, 3 colleges, and 22 hospitals.

The town of Cuba is, properly speaking, the capital of the island, but the governor and captain-general reside at the Havannah. The following is a list of the cities, towns, and settlements.

Cities.	*Settlements.*
Havannah.	Consolacion.
Cuba.	Los Pinos.
Baracoa.	Baxa.
Holguin.	Mantua.
Matanzas.	Guacamaro.
Trinidad.	Las Tuscas.
Santa Maria del Rosario.	Yara.
San Juan de Taruco.	Las Piedras.
Compostela.	Cubita.
	Vertientes.
Towns.	San Pedro.
Bayamo.	Pamarejo.
Puerto del Principe.	Cupey.
S. Felipe and Santiago.	Arroyo de Arenas.
S. Juan de los Remedios.	Filipinas.
Santi Espiritus.	Jiguam.
Santa Clara.	Caney.
Guanavacoa.	Tiguabos.
Santiago de las Vegas.	El Prado.

* The Abbé Raynal estimated the produce only at 4,675,000 pounds.

Moron.	Alvarez.
San Miguel.	Hanavana.
El Cano.	Macuriges.
Managua.	Guanajay.
Guines.	El Ciego.
Rio Blanco.	Cacarajicaras.
Guamutas.	Pinal del Rio.

The island of Cuba contains 11 very large and convenient bays, and many secure harbours, of which the principal are the port of Havannah, and the bay of Mataca. The harbour of the Havannah is large and safe, and is capable of containing about 1000 vessels. It possesses numerous and excellent fortifications, and has always been regarded as the military port of Mexico. A hostile squadron can anchor only at the foot of the castle of Saint John D'Ulua, which rises like a rock in the middle of the sea; and it is generally supposed that this fort is capable of holding out till the land-forces descend from the central table land, and till the health of the besiegers is affected by the insalubrity of the climate.

The bay of Mataca is very deep and spacious. It receives the sea by a very large canal; and, in consequence of two or three rivers discharging themselves into the bay, it is much frequented, both from the facility of procuring water, and from the abundance of refreshment which can be obtained.

Owing to the great expence of maintaining the squadrons which were stationed at Cuba during the last war, the sum required for the interior administration of Cuba is very great, amounting to no less than 1,826,000 piastres. This sum is made up of the following items, taken at an average from the years between 1788 and 1792.

	Piastres.
1. Aid to the internal government, *attencion de tierra*, for Santiago de Cuba	146,000
Ditto for the Havannah	290,000
2. Maritime expences, *attencion maritima* *	740,000
3. Expence of maintaining the fortifications of the Havannah	150,000
4. Purchase-money of tobacco from the island of Cuba, which goes into Spain	500,000
	1,826,000

These enormous charges almost entirely swallow up the revenues which the royal treasury receive from the island, which amounted only to 2,500,000 piastres, not including the annual situado from Mexico.

In the spring of 1804, when Humboldt was in Cuba, the following was its military state:

	Men.
1. Disciplined militia (infantry) at the Havannah	1,442
At the Villa de Puerto del Principe	721
2. Disciplined militia (cavalry) at the Havannah, and its jurisdiction	517
3. County militia (undisciplined) to the east of the Havannah and of Matanzas	7,995
To the west of the Havannah	5,688
In the suburbs of the Havannah	1,368
In the jurisdiction of the four towns	2,640
In that of the Puerto del Principe	1,728
In that of Santiago de Cuba	2,412
Total force	24,511

Humboldt is of opinion, that Cuba could command for its defence a body of 36,000 whites, from the age of 16 to 45.

The island of Cuba is supplied with a great quantity of provisions, but especially salt meat, from the coast of the Caraccas; but in the time of a war with England, the navigation to the Havannah is extremely dangerous, from the necessity of doubling Cape St Antonio. To avoid these dangers, an interior communication between the northern and southern coasts of the island has been projected. It is proposed to open a navigable canal for flat boats, through an extent of eighteen leagues, from the Gulf of Batabano to the Havannah, passing through the beautiful plains of the district of Los Guines. This canal will require few locks, and will not only fertilize the country by irrigation, but will convey to the Havannah, by a short and a safe route, the salted provisions, cocoa, indigo, and other productions of the Terra Firma.

The population of the island of Cuba, in 1774, amounted only to 171,628 inhabitants, including 44,328 slaves, and from 5000 to 6000 negroes. The number of negroes brought into Cuba, from 1789 to 1803, exceeded 76,000; and during the last four years of this period the number was 34,500, or more than 8600 annually. In 1804, according to Humboldt, the population of the island stood thus:

1. Freemen,		
Whites	234,000	
People of colour	90,000	
		324,000
2. Slaves		108,000
Total population,		432,000

That is, in every 100 inhabitants there are 54 creole and European whites 21 men of colour, and 25 slaves.

The following important geographic positions in the island of Cuba, and the small adjacent islands, we owe to M. Humboldt:

	Long. West from Greenwich Observatory.	Latitude.
The Havannah, the Morro	82° 22′ 53″	23° 9′ 27″
The Trinidad of Cuba	80 0 51	21 48 20
Cape St Antonio, N. W.	84 57 7	21 55 0
Punta de Mata, Hambre	82 17 30	
Bocca de Xagua	80 34 7	
Cayo Flamingo	81 43 7	22 0 6
Cayo de Piedras	81 16 57	21 56 40

This island was discovered by Columbus in 1492, and in 1494 it was circumnavigated by Nicholas de Obando.

See Humboldt's *Political Essay on the Kingdom of New Spain*, passim; Raynal's *History of the East and West Indies*; Thomson's *Alcedo*; and Peuchet's *Dictionnaire de la Geographie Commerçante*. See also the article HAVANNAH, and WEST INDIES. (*w*)

CUBÆA, a genus of plants of the class Decandria, and order Monogynia. See BOTANY, p. 210.

CUCKOO. See ORNITHOLOGY.

CUCUBALUS, a genus of plants of the class Decandria, and order Trigynia. See BOTANY, p. 217.

CUCULLARIA, a genus of plants of the class Monandria, and order Monogynia See BOTANY, p. 82.

CUCULUS. See ORNITHOLOGY.

CUCUMIS, a genus of plants of the class Monœcia, and order Monadelphia. See BOTANY, p. 330.

* This includes 700,000 piastres for the port and dockyards of the Havannah, and 40,000 for the vessels stationed off the coast of the Mosquitos

CUCURBITA, a genus of plants of the class Monœcia, and order Monadelphia. See BOTANY, p. 330.

CUDDALORE, a town of Hindostan, on the coast of Coromandel, situated about a mile to the south of Fort St David. The town is about three quarters of a mile long from north to south, and extends about half a mile from east to west. It is fortified on three sides, the side towards the sea being in a great measure open. The river, however, which passes between Fort St David and the town, flows along the eastern side of the city, and has thrown up a huge mound of sand at its embouchure, which in some means supplies the place of a fortification. The river, which is small, and navigable only by boats, is shut up by a bar at its mouth. The pagoda of Trivada, which forms a citadel to a large pettah, or town, stands a little above Cuddalore. The places which give a safe anchorage are 1½ mile from the shore, the flagstaff bearing N. W. and Fort St David N. N. W.

The town is populous, and carries on a considerable trade. Dimities, and various kinds of piece goods, similar to those of Surat in dimensions, colour, and qualities, are manufactured at Cuddalore, and the prices are nearly the same as at Surat.

In the year 1686, Mr Elihu Yale purchased the site of this town, and a small district, for the use of the India Company, for £31,000, from a Mahratta prince, and the fortifications gradually acquired strength. The French, under General Lally, took the place on the 1st of June 1758, after a siege of five weeks. The fortifications were completely destroyed; but when the town was restored to Britain at the peace, it soon recovered its prosperity. It was again taken by the French in 1781; and in 1783, after a severe contest, it fell into the hands of the British. East Long. 79° 50′, North Lat. 11° 43′. See Milburn's *Oriental Commerce*, vol. i. p. 376, Lond. 1813. (π)

CUDWORTH, RALPH, a celebrated metaphysician and divine, was born in 1617, at Aller, in Somersetshire, where his father was rector. After receiving the usual course of education, partly under the care of his father, and partly under that of his father-in-law, he was admitted, at the early age of thirteen, as a pensioner of Emanuel College, Cambridge, where he was matriculated in the year 1632. Having taken his degree of Master of Arts in 1637, and being elected a fellow of Emanuel College in the following year, his reputation as a tutor became so great, that he had no fewer than twenty-eight pupils at one time, among whom were the celebrated Sir William Temple and Archbishop Tillotson. He was soon afterwards appointed by his college to the rectory of North Cadbury, in the county of Somerset. In 1642, he published *A Discourse concerning the true Nature of the Lord's Supper*, and *The Union of Christ and the Church Shadowed, or in a Shadow*. In 1644, Cudworth took the degree of Bachelor of Divinity, and in the same year he was elected Master of Clarehall, when Dr Paske was ejected from that situation by the parliamentary visitors. In 1645, he was elected Regius Professor of Hebrew; and he now devoted the whole of his attention to his studies and academical duties. In 1651, he took the degree of Doctor in Divinity; but, owing to the embarrassed state of his finances, he was compelled for a while to quit the university. He was, however, speedily recalled, and in 1654 he was appointed to the head of Christ's College, Cambridge; a situation in which he spent the remainder of his days. In the year 1656–7, he was one of the persons who were nominated by a committee of parliament to deliberate about a new translation of the Bible. After the restoration of Charles II. he was presented to the vicarage of Ashwell, in Herefordshire; and in 1678, when he was installed prebendary of Gloucester, he published his great work, entitled *The True Intellectual System of the Universe, the first Part, wherein all the Reason and Philosophy of Atheism is confuted, and its impossibility demonstrated.* The principal object of this work is to refute the principles of atheism; and in the execution of this task, he has combined a great acuteness of reasoning with the most profound knowledge of ancient literature. His attachment, however, to the Platonic philosophy, has thrown an air of mysticism over some of his metaphysical opinions; and his doctrine of the Plastic nature, is supposed by Bayle to have given great advantage to the Atheists.

Beside the works which have been mentioned, Cudworth published some Sermons, and has left behind him several manuscripts, which are now lodged in the British Museum. The following is a list of them:

1. A Treatise concerning Moral Good and Evil.
2. A Treatise of Liberty and Necessity, wherein the foundations of the philosophy of atheism are destroyed, the certainty of morality established, and the nature of it explained.
3. A Commentary on the Seventy Weeks mentioned by the prophet Daniel, wherein the several explications of them by the Jews and some Christian writers are examined and confuted. 2 vols, folio.
4. A Treatise on the Creation of the World, and the Immortality of the Soul. 1 vol. 8vo.
5. Of the Learning of the Hebrews.
6. An Explanation of Hobbes' Notions concerning the Nature of God, and the Extension of Spirits.

Cudworth died at Cambridge in 1688, in the 71st year of his age. See the article ATHEISM, for an account of his *Intellectual System*. (o)

CUELLARA, a genus of plants of the class Decandria, and order Monogynia. See BOTANY, p. 222.

CUENCA, SANTA ANA DE, the capital of a province of the same name in the kingdom of Quito, is situated in the delightful plain of Yunquilla, which is about six leagues and a half long, and as many in width. This valley is watered by four rivers: the Machangara, which runs about half a league to the north of the city; the Matadero, which runs close to the south side of the city; the Yanuncay, which is distant from Cuenca about a quarter of a league; and the Los Banos, which is at the same distance. All these rivers, which are crossed by bridges, and are at some seasons fordable, unite at a small distance from Cuenca, and form the large river of Pante.

The city of Cuenca is classed by Ulloa among those of the fourth order, and is regarded as one of the most beautiful in the kingdom. The streets, which run in straight lines, are tolerably broad. The houses, which are generally of one story, are built with unburnt bricks, and are covered with tiles; and the suburbs, which the Indians inhabit, are, as usual, mean and irregular. The parish church, which was erected into a cathedral in 1786, is a magnificent building. The hospital is handsome and convenient, and well attended. The five convents, viz. of the order of St Francis, St Domingo, St Augustin, St Peter Nolasco,—the college, which formerly belonged to the Jesuits,—the two monasteries of nuns, viz. that of La Conception and of Santa Teresa, are all buildings of a very superior order.

The climate of Cuenca is mild and healthy; but sudden tempests, accompanied with dreadful thunder and lightning, often take place when the sky is clear. Every kind of flesh; and pulse, vegetables, and fruits, abound in the neighbourhood.

The women of this province are very industrious; and the baizes and other articles which they fabricate, which are esteemed for their quality and brilliancy of colour, form a great article of commerce. A hat manufactory was established here some years ago, which has proved one of the best and most useful in the city. Sugar is made in great quantities, and is in high repute; and the conserves of fruits, called the *caxetas de Cuenca*, are much admired. Large cheeses, resembling those of Parma, are made in Cuenca, and find a ready sale in Lima, Quito, and other cities. In the territory to the south of the city is the height of Tarqui, where the base was measured by Bouguer and Condamine for their trigonometrical operations. This city was founded in 1557 by Gil Ramirez Davalos. Ulloa states the population of this town at 20,000 or 30,000; but, according to much later accounts, it does not exceed 14,000. West Long. 79° 14′ 15″, South Lat. 2° 55′ 3″. See Peru and Quito. (π)

CULDEES, a body of religious, who chiefly resided in Scotland, Ireland, and some of the adjacent isles. The name has been also written *Keldees* and *Kyldees*. Various etymons have been given of it. Two of these seem to have superior claims to attention. It may be deduced either from Irish *ceile*, or *gille*, a servant, and *De, Dia*, God; or from *cuil, ceal*, in Welsh *cêl*, a sequestered corner, a retreat. The latter seems to derive support from the established sense of *Kil*, retained in the names of so many places, which, in an early age, have been consecrated to religion.

It is more than probable, that Christianity had found its way into Scotland before the close of the second century; and that it continued to be professed by a few scattered individuals, even before the arrival of Ninian, in the beginning of the fifth. But we have no proof of the existence of any religious societies observing a particular institute till the year 563, when Columba landed in Hii, or Iona; which, in honour of him, was afterwards called *I-colum-kill, i. e.* the *isle* of *Colum*, or Columba, of the *cells*. He was born in Ireland, A. 521; and, after founding many seminaries of religion there, prompted by zeal for the propagation of Christianity, set sail for Scotland with twelve companions. According to Bede, having converted the northern Picts, he received from Brudi, their king, the island of Hii in possession, for the purpose of erecting a monastery. Here he almost constantly resided till the year 597, when he died. He made occasional visits to the mainland, proceeding even as far as to Inverness; also to Ireland, where he was held in high estimation. As he was himself much devoted to the study of the Holy Scriptures, he taught his disciples to confirm their doctrines by testimonies brought from this unpolluted fountain, and declared that only to be the divine counsel which he found there. His followers, faithful to his instructions, "would receive those things only which are contained in the writings of the prophets, evangelists, and apostles, diligently observing the works of piety and purity;" Bede, *Hist.* iii. 4. They lived, indeed, according to a certain institute, which, it is said, was composed by their venerable instructor. But there was this remarkable distinction between them and those societies properly called monastic, that they were not associated expressly for the purpose of observing this rule. While they seem to have reckoned something of this kind necessary for the preservation of order, and for the attainment of habits of diligence, their great design was, by the instruction of those committed to their charge, to train them up for the work of the ministry. Hence it has been justly observed, that the Culdean fraternities may more properly be viewed as colleges than as monasteries, as being, in fact, the seminaries of the church both in North Britain and in Ireland. There were also Culdees in Wales; and for many ages, the Christians of that country held the same doctrines, and observed the same rites, with their Scottish and Irish brethren. The presbyters not only acted as the ministers of religion to those in their vicinity, but were still instructing others, and sending forth missionaries whenever they had a call, or any prospect of success.

In each regular establishment of the Culdees, it would appear that there were twelve brethren, with one who presided over them. Their ecclesiastical government has been viewed as materially the same with the Presbyterian. Their president, or abbot, was not a bishop, but a presbyter; to whose authority, as we learn from Bede, even the bishops of the district were subject. In their meetings, all matters were settled by plurality of voices. The members of this council had the general designation of *seniores*, or elders. To them, collectively, belonged the trial of the gifts of those who had been educated in their seminaries, when they were to be employed in the public ministry; from them they received ordination and mission; and to them they were amenable in the discharge of their office. Those whom they thus employed are, by ancient writers, often denominated *bishops*. But that they attached to this designation no dignity superior to that of *presbyter*, appears incontrovertible from their being afterwards called to account, and sometimes censured by the fraternity. It has been asserted, by the friends of diocesan episcopacy, that a bishop *must* always have resided at Iona for the purpose of conferring ordination. But there is not the slightest evidence of this. The contrary appears from all the records of these early ages. We learn from the Saxon Chronicle, that "there was always an abbot at Hii, but no bishop."

It is a singular fact, that those who were first acknowledged as bishops in the northern parts of England, and were indeed instrumental in the introduction of Christianity there, were not only trained up at Iona, but received all their authority from the council of seniors in that island. This was the case with respect to Corman, the bishop of the Northumbrians, as well as Aidan, Finan, and Colman, who succeeded each other in this mission. From the testimony of Bede it is evident, that by means of Scottish missionaries, or of those whom they had instructed and ordained, not only the Northumbrians, but the Middle-Angles, the Mercians, and East-Saxons, all the way to the river Thames, that is, the inhabitants of by far the greatest part of the country now called England, were converted to Christianity, and for some time acknowledged subjection to the ecclesiastical government of the Scots. The latter lost their influence, merely because their missionaries chose rather to give up their charges, than to submit to the prevailing influence of the church of

Rome, to which the Saxons of the West and of Kent had subjected themselves. See Bede, *Hist.* iii. 21—26.

The seniors at Iona did not confine their attention to England. They established religious houses, similar to their own, in many places in Scotland. The most ancient of these seems to have been at Abernethy, accounted the capital of the Pictish kingdom. The Culdean monastery, or college there, appears to have been founded about the year 600. The idea, that this was the primary seat of the chief episcopate among the Picts, which, it is said, was afterwards transferred to St Andrews, most probably originated from the misapprehension, or misrepresentation, by monkish writers, of the power that belonged to the Culdean council, which, in an early age, might extend over a great part of Scotland, by reason of the remote situation of Iona. It appears that there was a society of Culdees in St Serf's isle, in Lochlevin, before the close of the seventh century. They were soon after this established at Dunkeld; long before it became an episcopal see. The Pictish princes were disposed to make this a second Iona, either because of the distance, or on account of the desolation, of the other by the invasions of the Scandinavians. Hence the *abbot* of Dunkeld was also called *primate* of Pictland. The Culdees, it would seem, had a foundation at St Andrews about the beginning of the ninth century. They were settled at Brechin before it was made a bishopric. We have some proof of their establishment at Dunblane about the year 1000. They were also fixed at Monimusk, Dunfermline, and Scone. Kirkaldy, Culross, and Melrose, are numbered among their seats, as well as Govan, Abercorn, Tyningham, &c.

Their doctrines were not less unpalatable, than their mode of government, to the friends of the church of Rome. In England, in a very early period, the adherents of the popish missionary Augustine were viewed by the delegates from Iona in the light of heretics. They accordingly refused to hold communion with them. Matters were carried so high in support of the Roman authority in the synod of Stroneschalch, now Whitby, in England, A. 662, that Colman, the Scottish bishop of Lindisfarne, left his bishopric, and with his adherents returned to Scotland. Thus, as Bede informs us, "the catholic institution daily increasing, all the Scots who resided among the Angles either conformed to them, or returned to their own country;" *Hist.* iii. 25, 26, 29. It was decreed in the council of Cealhythe, A. 816, that no Scottish priest should be allowed to perform any duty of his function in England. But in Scotland the Culdean doctrine had taken deeper root, and, although equally offensive to the votaries of Rome, kept its ground for several centuries. The popish writers themselves celebrate the piety, the purity, the humility, and even the learning, of the Culdees; but while they were displeased with the simplicity, or what they deemed the barbarism of their worship, they charged them with various deviations from the faith of the Catholic church. It was not the least of these, that they did not observe Easter at the proper time. They did not acknowledge auricular confession; they rejected penance and authoritative absolution; they made no use of chrism in baptism; confirmation was unknown; they opposed the doctrine of the real presence; they withstood the idolatrous worship of saints and angels, dedicating all their churches to the Holy Trinity; they denied the doctrine of works of supererogation; they were enemies to the celibacy of the clergy, themselves living in the married state. One sweeping charge brought against them is, that they preferred their own opinions "to the statutes of the holy fathers."

The Scots, having received the Christian faith by the labours of the Culdees, long withstood the errors and usurpations of Rome. It was not till the twelfth century that their influence began to decline. Till the close of the eleventh, it appears that they continued to differ from the Romish church as to the time of observing Lent and Easter. The pious Margaret, queen to Malcolm Canmore, who has been canonized as the patroness of Scotland, being an Anglo-Saxon princess, and having been educated on the continent, may well be supposed to have been partial to those modes of worship to which she had been accustomed from her infancy. We find, accordingly, that she was offended at "certain erroneous practices" which prevailed in the Scottish church; and, with the view of reforming these, held frequent conferences with the clergy, in which the king acted as interpreter. Her arguments, as we learn from Turgot, her confessor, at length prevailed. They agreed to observe Lent according to the Catholic institution. The same writer says: "In some places of Scotland there were certain persons who were accustomed to celebrate masses, I know not by what barbarous rite, contrary to the universal practice of the church." He adds, that "the queen, from holy zeal, was at the greatest pains to annihilate this custom, that no one of the Scottish nation might henceforth presume to observe it;" *Vit. Margaret.* c. 2. s. 16. Papebroch, in his Notes, strangely views the word *missæ* as signifying *fairs.* Lord Hailes does not seem to have understood the meaning of this crimination. Vid. *Annals*, i. 38, 39, N. But this is the very charge that was afterwards brought against the Culdees in the Register of the Priory of St Andrews, supposed to have been written about the year 1140. They "celebrated their office, *after their own manner*, in a certain very small corner of the church." *More suo* of the Register, is equivalent to *nescio quo ritu barbaro* of Turgot. This also exactly accords with the account given by the celebrated St Bernard of the Irish Culdees, when Malachy entered on the bishopric of Connor. "He never had met with any," he says, "so perverse in their manners, so beastly in their rites, so impious in their faith, so barbarous as to their institutes;" *Vit. Malach* c. 6. *ap. Messingham*, p. 357. The similarity of the language used in the Register of St Andrews to that of Turgot, affords a proof that, notwithstanding the concessions made to the zealous queen, the influence of her exertions had not outlived herself.

We hear of no further attempts against them till the reign of Alexander I. He, although attached to St Columba, thought the modes of worship observed by his followers too simple; and therefore "delivered up the church" at Scone, which had been dedicated in honour of the Holy Trinity, "to God himself, and St Mary, and St Michael, and St John, and St Laurence, and St Augustine." Vid. *Chart. Dalrymple's Coll.* p. 371, 372. His brother David, *the Saint*, pursued measures still more effectual. These were at first of an artful description. As he increased the number of the episcopal sees, which tended greatly to weaken the authority of the Culdees; he promoted some of the abbots of their monasteries to the dignity of the episcopate, preserving to the Culdees, possessed of parochial churches, their benefices during life. Those whom he appointed to the other bishoprics, when they became vacant, were generally foreigners, who had been strictly trained up in the Romish religion. But the great plan devised for the overthrow of the Culdees, was the introduction of *Canons Regular* into the places which they had formerly possessed. These had been made a permanent order in the eleventh century; and, being patronized by the Pope, were rigidly devoted to the interests and forms of the church of Rome, and zealous for the extension of the authority of their ghostly father. The professed design of their introduction was, that "*religion* might be established," the country being represented as previously in a state of heathenism. *Wyntown's Cron.* B. vii. c. 6. v. 125. In some instances, where canons were introduced, the Culdees were permitted to retain their rights, and to live for a time distinctly; in others they were tolerated, if they would consent to live according to the canonical rule. As, in episcopal sees, they had exercised the right of electing the bishops, this privilege was taken from them, and conferred on the canons. Their lands, tithes, and other rights, even their churches and convents, were gradually wrested from them, and conferred on their antagonists. When at length reluctantly reduced to the necessity of appealing to the Pope, delegates were appointed who were known to be inimical to their interests; and such decisions were given as weakened their power still more. We have no historical account of their existence as a distinct body later than the year 1309, about which time those of St Andrew's at least were completely "subjected to the bishop."

It is singular, that even in Iona an attempt had been made, as early as the beginning of the eighth century, to effect a partial conformity between the Culdees and the church of Rome. Adomnan, their abbot, in consequence of a visit to the Saxon monks of Girwy, became a proselyte to their unimportant dogma, as to the time of the observation of Easter. The Culdees, however, continued firm in their adherence to the custom of their predecessors. Nectan III. king of the Picts, having adopted the catholic system on this head, resolved to accomplish by force what Adomnan had failed to do by persuasion. We learn, accordingly, from the Annals of Ulster, that, A. D. 716, he "expelled the family of Hii beyond Drum-albin." This can be understood of those only who were refractory; for Ecgberht, a Saxon monk, was at this very time sent from Girwy to Iona, where he remained for thirteen years. From him the monks of this island "received the catholic rites of life." Bed. *Hist.* vol. xxi. During his residence here, a considerable number of the Culdean presbyters had voluntarily retired to Ireland; and had done so, as refusing to submit to the Romish innovations. For there, it is said, "the law was renewed;" *i. e.* they observed their own customs without disturbance. After the death of Nectan, and of Ecgberht his ghostly coadjutor, they returned to Iona. Here the society enjoyed tranquillity for more than sixty years. During several succeeding centuries, they were harassed by oppressors still more severe; their island being frequently desolated by the Danes.

After the erection of the greater Culdee establishments on the mainland, those especially of Abernethy, Dunkeld, and St Andrew's, the religious influence of the parent foundation necessarily declined. But, amidst accumulated hardships, it subsisted so late as the beginning of the thirteenth century; for, in the year 1203, when Ceallach had erected a monastery in the island, apparently for the reception of one of the Romish orders, it was demolished by "the learned of the place," abetted by the clergy of the north of Ireland.

With respect to the Culdees on the mainland, it has been seen that they retained their corporate form, in some places at least, till the beginning of the fourteenth century. The very year in which they are last mentioned in our records as a body, is that assigned to the appearance of those contemptuously called *Lollards* in Germany. Soon after, Wickliffe propagated that doctrine in England, which formed the basis of the Reformation. In the following century, many of those who adhered to the same doctrine were branded with the name of *Lollards* in Scotland. Thus, although we cannot trace the Culdees down to the very era of the Reformation, there is reason to think, that individuals, adhering to their principles, continued to discharge the pastoral duties, especially in those places which were more remote from the episcopal seats. It has been viewed as no contemptible proof of the permanent regard which the Scots had to the memory of the Culdees, that, as soon as they had the power in their hands, they preferred a form of ecclesiastical government nearly allied to that which had so long subsisted among these venerable presbyters. To the same source, perhaps, ought we to trace the hereditary antipathy which has been manifested by the Scottish nation to pomp and ceremony in divine worship. Hence, all the power of the civil government has, even in later times, been unable to give a permanent establishment to prelacy. The account given of the Culdees, nearly a thousand years ago, would seem to be permanently descriptive of the Scottish character in matters of religion; "*Suum officium* more suo *celebrabant.*"

It is universally admitted, that the difference between the lower classes of society in England and those of the same description in Scotland, both with respect to religious knowledge and moral conduct, is very striking. Some writers, whose attention has been arrested by this singular circumstance, and who could not be influenced by local attachments, have ascribed the disparity to the relative influence, however remote it may seem, of the doctrine and example of the Culdees. Notwithstanding their great disinterestedness and diligence in propagating the gospel in England, these good men, it has been remarked, within thirty years after the commencement of their mission, were obliged to give way to the adherents of Rome; whereas the Scots, it is certainly known, enjoyed the benefit of their labours for more than seven centuries, and seem to have still retained their predilection for the doctrines and modes which they so early received.

See Dr Jamieson's *Historical Account of the ancient Culdees, and of their Settlements in Scotland, England, and Ireland;* Edin. 1811. (J.)

CULLEN, William, M. D. a late eminent physician and celebrated professor of medicine in the University of Edinburgh, was born in the county of Lanark, in the west of Scotland, on the 11th of December 1712. His parents were respectable, but not in affluent circumstances; and we have only been able to learn that his father filled the office of bailie or magistrate of the burgh of Hamilton. Of his early education no circumstances have reached our knowledge; but it is probable that, after the ordinary initiation in Latin at the school of his native parish, he might enjoy the usual advantage of a short course of classical study in the neighbouring university of Glasgow, preparatory to entering upon professional pursuits. At an early period he was bound apprentice to a surgeon apothecary in

Glasgow, during which service he would doubtless attend such medical lectures as were then given in the university of that city.

On the expiry of his apprenticeship, he made several voyages as surgeon to a West India ship which sailed from the port of London: but, not relishing that mode of life, he settled, while yet very young, as a country surgeon in the parish of Shotts, a rural district only a few miles east from Glasgow, where he could merely have earned a scanty and precarious income by his practice among poor farmers and cottagers. Even here his uncommon attainments in science, the well-tempered vivacity of his conversation, and the rare urbanity of his manners, soon acquired him a respectable acquaintance among the gentlemen of the neighbourhood, by whom he was considered as an attentive, enlightened, and humane practitioner, and a most engaging and instructive companion in the hours of social intercourse. At this early period, an incident occurred that had considerable influence on his future fortunes, and shews the extensive progress he had already made in the branches of study connected with his professional pursuits. Archibald Duke of Argyle, who long bore almost unrestrained sway in the politics of Scotland, happened to visit a gentleman of some consequence near Shotts. The Duke, who did not confine his attention to politics, was, at that time, engaged in some chemical research that required elucidation by experiment, and was in want of apparatus for the purpose. On stating his difficulties to his host, Cullen was immediately mentioned as a person who might probably be able to assist him, and was accordingly introduced to his Grace, who was much pleased with the scientific attainments and polite address of the young village doctor, and afterwards promoted his views of professional advancement on several occasions.

After a short residence in the parish of Shotts, he removed to the town of Hamilton, entering into copartnery with William Hunter, a young man in similar narrow circumstances with himself, and of congenial talents. One chief object of this connection was to enable the contracting parties to prosecute their studies, by means of the emoluments arising from their joint practice. Cullen is said to have engaged chiefly in the medical department, while Hunter devoted himself to surgery and midwifery, to which it seems the nerves of Cullen were not adequate. It was agreed between them, that they should prosecute their studies in alternate winters, that while the one was thus employed the other should conduct the business at home, and that each should be at liberty to attend the medical school that he might prefer. Cullen had the first turn in this singular agreement, so honourable as well as advantageous to both, and made choice of the University of Edinburgh, which was then fast rising into fame as a school of medicine, and to the celebrity of which he afterwards so largely contributed. Next winter, Hunter gave the preference to London, probably attracted by the superior advantages which it afforded for the study of anatomy, surgery, and midwifery. And meeting with great encouragement and success, he continued to reside and practice there during the remainder of his life. Thus soon terminated a copartnery, perhaps unexampled in the annals of science, between two young men who both rose to the summit of professional eminence, though in different lines, in the two British capitals. Cullen and Hunter continued ever after to correspond on the most cordial terms of friendship; but it is believed they never afterwards met, though each of them lived to an advanced age.

Left by himself at Hamilton, Cullen soon rose above the ordinary estimation of a village practitioner, by the unembarrassed elegance of his manners, the kind and soothing attentions which he paid to his patients, and his superior, yet unassuming display of social talents and scientific acquirements. Soon after his removal to that town, the Duke of Hamilton, who occasionally resided in what is called the *Palace*, was taken suddenly ill, and young Cullen was called to visit him. In the course of his attendance, the Duke was much pleased with his professional assiduity and unexpected display of ingenious, sprightly, and instructive conversation. The disease with which the Duke was at this time afflicted, was of such a nature as to resist the effects of the first applications, and Dr Clerk, then a physician of great eminence at Edinburgh, was sent for. This circumstance, far from injuring the character of Cullen, tended greatly to his advantage; as Clerk expressed entire satisfaction with his previous treatment, and became his eulogist upon every occasion. Cullen never forgot this kindness; and when Clerk died, delivered a public oration in his praise in the University of Edinburgh.

Thus early introduced, almost by accident, to the notice of the two noblemen of highest rank and influence in the country at that time, and acquiring the esteem and favour of both, Cullen soon emerged from the humble sphere in which he had been hitherto placed, to move in a more brilliant circle, as a physician and professor successively, in the two principal cities and most celebrated universities of Scotland. While he continued to reside at Hamilton, and was still in early life, he married Miss Johnston, a young lady nearly of his own age, and the daughter of a neighbouring country clergyman. This lady is said to have been sensible, beautiful in her person, amiable in her disposition, elegant in her manners, and of uncommon equanimity of temper. She also brought a small fortune, which would at that time be no small help towards the establishment of a young man. After becoming the mother of a numerous family, and participating with her husband in the rise of character and fortune, which he so richly merited, Mrs Cullen died at an advanced age in the summer of 1786, not quite four years before the Doctor.

Cullen took the degree of Doctor of Medicine in the University of Glasgow, on the 4th September 1740; and, in 1746, when about 25 years of age, he was removed from being a country practitioner at Hamilton, to the more exalted situation of Lecturer in Chemistry in the University of Glasgow. In that university, as in some others, a lecturer gives lessons to the students exactly as a professor, but is not admitted into the corporate body, and has no participation in the funds, except in so far as a limited salary may be granted to him by the Senatus Academicus, with whom alone the management of them is entrusted.

Chemistry was then in a great measure a nascent art, hardly deserving the name of a science, but had escaped from the mystic trammels and wild reveries of the alchymists, and was beginning to put on somewhat of the garb of a department in physical science, in consequence of the ingenuity of Becker and Stahl, and the industry of Boerhaave. In teaching the almost unconnected and chaotic multitude of facts then belonging to chemistry, which were held together at that

Cullen. time by the theory of phlogiston, Dr Cullen displayed uncommon talents for distinct philosophical arrangement, for extraordinary vivacity and clearness of illustration, for eloquent language, and apt experiment. By these he rendered his lectures exceedingly interesting to his pupils, and soon acquired a popularity among the students far beyond what the other medical professors enjoyed—a circumstance which is said to have engendered no small degree of envy among them.

Besides acquiring fame in the discharge of his academical duties, Cullen rose rapidly in reputation and practice as a physician; and, in 1751, at the age of thirty, was appointed Regius Professor of Medicine. In this new situation he displayed the same qualities which had already distinguished him, and with the same success; and his celebrity, both as a professor and a physician, continued to increase.

In 1756, by the death of Dr Plummer, the chair of chemistry in the University of Edinburgh became vacant, and Cullen received an unanimous invitation from the Magistrates and Town Council of that city, to supply the vacancy, which he accordingly accepted. Till then the study of chemistry had been of small account in the University of Edinburgh, and the lectures on that science were attended by a very inconsiderable number of students. The scene was now entirely changed, and the new professor became so popular, that the chemical lectures were more numerously attended than any other in the university, those on anatomy excepted. To the students, Cullen presented a new and fascinating source of instruction, in the luminous arrangement which he adopted, the easy flowing eloquence with which he expressed himself, and the well devised experiments which he employed to illustrate his subject; and he is said to have been praised on all occasions by his pupils in such rapturous strains of eulogy, as to give much dissatisfaction to his less popular colleagues.

A party is said to have been formed at this time among the students for injuring his fame and character, by misrepresenting his doctrines; and so successful were they, that some even of the most intelligent professors in the university thought it their duty publicly to impugn the doctrines that were imputed to him, and some time elapsed before they discovered the low and scandalous arts by which they had been deceived. During this strange ferment, Cullen steadily continued his progress without taking the smallest notice of what was going on; nor did he ever listen to any tales respecting his colleagues, or advert to any of the doctrines they taught, considered personally as theirs, though he certainly opposed, and finally overturned the general medical theories which they had embraced, and which were then universally followed by the disciples of Boerhaave. These mean and unprincipled attempts to injure the reputation of Cullen, at his first appearance in the university of Edinburgh, completely failed, as the other professors were at length sensible that they had been misled and imposed upon by false representations; and that harmony which had thus been maliciously disturbed, was at length happily restored. Disputations, indeed, always carried on with keenness, and sometimes with singular acrimony, long prevailed among the students in their societies, respecting the contending doctrines; but these were confined to the students, and in the main tended much to their improvement, by urging them to study with increased energy, that they might make a better figure in the debate.

In February 1763, the professorship of Materia Medica and Pharmacy became vacant by the death of Dr Alston, in the middle of the session. The patrons of the university appointed Dr Cullen to the vacant chair, and requested him to finish the course of lectures of that season, already half elapsed. Although thus under the necessity of proceeding to teach this new branch of medical science only a few days after his nomination, he determined to deliver an entire new course of lectures of his own composition, instead of reading those already prepared by his predecessor; and such was the high estimation in which he was held by the students, that the original eight or ten who had entered to the course of his predecessor, were soon joined by above an hundred others, even at that advanced period of the course.

By the death of Dr Whytt, in 1766, the chair of the Institutes of Medicine, usually called the Theory of Physic, became vacant, and Cullen was appointed by the Magistrates to that professorship also. On this occasion, he resigned the chemical chair in favour of the celebrated Dr Black, formerly his pupil, and his successor as lecturer on chemistry in the university of Glasgow.

Either in the same year with the death of Dr Whytt, or in that immediately following, Dr Rutherford, who had long given lectures on the Practice of Medicine, with great reputation, resigned that chair, to which Dr John Gregory was elected, though we believe Dr Cullen was also a candidate. For two subsequent sessions of the university, Dr Gregory and Dr Cullen continued to lecture respectively on the Practice and Theory; but we have been informed, that, in summer 1769, Dr Cullen opened a private course of lectures on the Practice, and before the conclusion of that course, a compromise took place between him and Dr Gregory, in consequence of which they were elected joint professors of the Practice and Theory, each to give lectures in alternate sessions on these two branches during their joint lives, and the survivor to have the choice of either chair at the decease of the other.

This was a wise and most beneficial arrangement—advantageous at once to the individuals more immediately concerned, and to the seminary in which they laboured. Both professors possessed superior talents, and they happily co-operated to forward the pursuits of the medical students, and to extend the reputation of the university; which, by their great abilities and excellent methods of teaching, combined with the eminence of their other colleagues in the medical faculty, rose rapidly to very high and well-merited celebrity as a school of medicine, annually attracting great numbers of students from all parts of the British dominions and colonies, and many from foreign countries, by whom its fame was diffused through all the civilized parts of the globe.

A period, however, was soon put to this arrangement, by the sudden death of Dr Gregory, who was cut off in the flower of his age and usefulness, to the great loss of medical science, and to the infinite regret of a numerous circle of friends and admirers. From that period, Dr Cullen continued to give lectures on the Practice of Medicine, till within a few months of his death, which took place at Edinburgh on the 10th February 1790, at the advanced age of seventy-seven years and two months.

Besides the lectures on the Practice of Medicine, and the other courses he before delivered from the several chairs which he had successively occupied, with so much honour to himself and advantage to the students, he also long gave regular courses of what are called Clinical Lectures, alternating with the other professors of the medical faculty. These are delivered on the actual cases of patients attended by the clinical professor of the season, accompanied by the pupils, in wards of the Royal Infirmary set apart for this purpose: an institution of most admirable utility, by which the medical students are initiated into all the minutiæ of real practice, and habituated to reason judiciously on the nature, symptoms, and diagnostics of diseases, and on the qualities, operation, and effects of remedies employed for curing them; instead of blindly following empyrical modes of prescription, merely because such and such nostrums have been recommended for such and such diseases.

As a philosopher and as a lecturer on various branches of medical science, the mind of Dr Cullen was not so much occupied in minutely examining the separate parts of the subjects on which his attentions were engaged, as in tracing the various relations, connexions, and dependencies, by which they constitute individual portions of one harmonious whole; and his singular talent for arranging, in lucid order, the numerous subjects on which he treated, joined to the easy, perspicuous, and flowing language in which he communicated his ideas, particularly distinguished him as a public lecturer. This faculty, however, could not, by itself, have merited the high applause which he so justly obtained. An accurate and extensive acquaintance with facts was necessary to give it its full exercise. His whole life, accordingly, was industriously and almost uninterruptedly employed in the collection of facts, by reading, by conversation, and by diligent observation in the course of discharging his professional duties, both public and private. These he marked with uncommon keenness of perception, as they occurred, without stopping at the time to record, or even to examine them in their several bearings; but he stored them up in his memory, for being afterwards brought forwards as occasion might require, to be then sifted, examined, and compared, in all their relations and connections, and applied as proofs and illustrations of the subjects to which they severally had reference.

All his prelections were delivered extempore, without having been previously committed to writing, and were only assisted by a few short notes or heads of discourse, merely to preserve the accustomed order of his general arrangement. This free and unconstrained manner of enunciation, gave to his lectures an appearance of ease, vivacity, and force, that is rarely found in academical discourses; so that they were never precisely the same, even upon the same subjects, in different seasons, but always presented something novel, at least in their language and illustrations. His mode of delivery was eloquent and energetic, and at the same time easy, flowing, and natural, on which account his lectures never failed to captivate his hearers, and command their unremitting attention. Even such of them as were unable to follow him in those profound views which he frequently presented, or could not fully comprehend the apt allusions to collateral subjects, at which he often hinted only as it were in passing, were yet unavoidably warmed in some measure by the vivacity of his manner. Those of his pupils, on the other hand, who were able to keep pace with him in his rapid career, found every faculty of their minds roused to action by the extensive views which he opened up to them, and were excited to such ardour of admiration and of study, as seemed incomprehensible to mere unconcerned spectators.

His influence upon young minds was much augmented by the captivating novelty of his speculative or theoretic opinions, and by the freedom with which he animadverted upon the medical systems that were chiefly in vogue at the commencement of his academical career, and which certainly afforded legitimate points of attack. At that period, the medical school of Edinburgh, closely following that of Leyden, was fast bound in the trammels of the Boerhaavian humoral pathology, which attempted to explain the nature of diseases, and to found the rationale of their cure upon a suppositi-tious leutor viscidity and acrimony of the fluids. Even in his first clinical lectures, before he became professor of the institutes of medicine, Dr Cullen bent the main strength of his pathological arguments to combat this doctrine. He succeeded in his attempt, having soon shaken its credit, and at last most completely overturned it. It is not meant to give any view, in this place, of the doctrine which he then endeavoured to substitute in the place of the one that he had exploded, and the establishment of which he afterwards effected, but it may be noticed, very generally, that he adopted and expanded the pathological opinions already advanced by Hoffman; according to which, the nature of disease was more rationally explained, by considering the errors induced, by their remote, occasional, and proximate causes, upon the actions of the living solids or vital motions, than by any supposeable vitiated condition of the fluids or humours, of which there is no evidence from fact and observation. *Ex vitio motuum microcosmicorum in solidis, potius quam ex variis affectionibus vitiosorum humorum.*

It cannot be asserted, however, that the doctrine of *Spasm and Atony* was much better founded in reason and observation than that of *Leutor Viscidity and Acrimony,* which it so completely superseded. But Dr Cullen certainly succeeded in setting free the minds of the students from the shackles of long established and uncontrouled authority, always injurious to the advancement of science, and taught them to think for themselves, by comparing reasonings and inductions with facts and observation. He thus introduced new and extensive views and speculations among the students, which, if not always satisfactory, were always ingenious, and afforded them excellent topics for discussion in their various societies. At an advanced period of Dr Cullen's life, such was the enthusiasm excited among the students on certain points of controversy arising out of his hypothesis, contrasted with another set up in opposition to it by a private lecturer, that several duels were fought in consequence; and it has been alleged, that Dr Cullen began at length to feel some of that jealousy towards a rival innovator, which he himself had inspired at the commencement of his own career. But it would extend our sketch to a most inconvenient length to attempt any elucidation of this medical controversy. Suffice it to say, that the Brunonian doctrine was in a great measure a modification of the Cullenian *Spasm and Atony,* disguised under new terms, and arranging all diseases under the heads of *Sthenic and Asthenic.* See the Life of Brown in this Work.

While the uncommon popularity which Dr Cullen enjoyed was chiefly owing to his great merit as a teacher, it was also much forwarded by the laudable pains he took to ingratiate himself with his pupils. He was cordially attentive to all their interests, invited them frequently to evening parties at his house, conversed with them upon the most familiar terms, endeavoured to solve all their doubts and difficulties, gave them the use of his extensive medical library, and treated them in every respect with the kindness of a friend, and the affection of a parent. In their sickness, he attended upon them as their physician, and uniformly refused to accept of any fees,—a species of generosity which had not been customary in Edinburgh before his time.

The high, and even enthusiastic favour in which he was held by the students to the very last, was strongly evinced by the many eulogies upon his character, to be found liberally interspersed among the numerous inaugural dissertations of his pupils, and by the affectionate addresses presented to him by the Royal Medical and Physical Societies upon his resignation of the practical chair in the university, a few months before his death.

No chemical discoveries of any moment have been attributed to Dr Cullen; but he was a most useful and successful teacher of the science, so far as it had then advanced, in consequence of the liberal and comprehensive views which he took of its facts and doctrines, and the admirable arrangement in which he presented these to his pupils. He also gave very complete histories of several of its departments, by an accurate collection and clear distribution of facts,—particularly of such facts as are connected with medicine and pharmacy. His only publication on the subject, was a small pamphlet, containing an account of some experiments on heat.

His lectures on materia medica, though necessarily put together in great haste, were so much admired, that copies of them, taken from notes, were multiplied among the students; and at length one of these copies was surreptitiously put to press in 1772. Dr Cullen at first obtained an interdict against this imperfect and piratical publication; but having undergone some corrections, it was afterwards allowed to proceed. He promised, at the time, to give an improved edition of the work, which he accordingly published in 1789, in two volumes quarto. This edition, though certainly more full, and perhaps more instructive than the former, greatly wants those fascinating and systematic general views of the subject by which it was recommended, and which the author perhaps endeavoured too much to alter or modify. Its inferiority may also have been in part occasioned by the energy of his mind beginning to decay, at his then advanced period of life. This work, however, materially differs from the ordinary systematic performances on the subject, and is in a great measure the philosophy of the materia medica, rather than a dry matter-of-fact history of its various topics. It is arranged according to the medical indications, and contains admirable introductory observations on each class, forming an excellent system of Therapeutics. Many also of the general doctrines in the practice of medicine are introduced, and these are even illustrated in some detail.

The character of Dr Cullen as a teacher of the theory and practice of medicine, is now only to be estimated from the works he published as text-books for his lectures.

While professor of the theory or institutes of medicine, he published a short text-book on that subject, but it was never completed or moulded into a regular treatise, and still remains in its original form, merely intimating the heads of his lectures in that department. The other, which was designed to be a text-book for the course of the practice, was entitled *First Lines of the Practice of Physic*. Of this, various editions appeared successively, enlarged and altered as his views expanded in the progress of his professional labours. The complete edition, not afterwards changed, appeared in 1784, in four volumes octavo. In this work, regarding the actions of the moving powers in the animal economy, as the leading principles of inquiry, in considering the diseases of the human body, he assumed, as formerly mentioned, the general doctrines previously advanced by Hoffman on this subject, but considerably corrected and extended. In the application of these to the consideration and explanation of the symptoms and nature of disease, he disclaims the adoption of what are usually termed hypothetical notions or theories, asserting that the doctrines he endeavours to establish are just inductions or generalizations from observed facts, in relation to the healthy and diseased states of the body; and he certainly has shewn himself a very faithful collector of facts, to which he allows all due weight in the course of his reasonings. He was not satisfied, however, with a mere empirical basis for medical practice, but always endeavoured to investigate the proximate cause of disease, or, in other words, the intimate nature of the diseased action, on which to ground a rational method of cure, fitted to restore that action from its vitiated to its natural and healthy state. The most remarkable of his attempts of this kind, is his doctrine respecting the proximate cause of fever, in which he endeavours to establish the coexistence of spasm and atony in the human body. However subtle the reasonings may be deemed, on which this and others of his opinions are founded, his work certainly possesses great merit in the excellent descriptions and sagacious discriminations which it contains, and in the full and commonly just views of practice which it displays and inculcates. For, though grounded upon all the refinements of speculation, it yet shews that he paid so much respect to experience, as to submit to its decisions on all points of practice, even at the risk of appearing occasionally to contradict his own speculative doctrines.

Another class-book is his *Synopsis Nosologiæ Methodicæ*, of which the third and complete edition appeared in 1782. This contains abstracts of the systematic nosologies of Sauvages, Linnæus, Vagel, and Sagar, as introductory to a new arrangement of his own, intended as an improvement upon all the others; and he has certainly succeeded in the task, as far perhaps as the nature of the subject could admit. The *First Lines of the Practice of Physic*, and the *Synopsis Nosologiæ Methodicæ*, still remain standard books, and are still perhaps unrivalled. A pamphlet, published in 1775, *Concerning the Recovery of Persons drowned, and seemingly dead*, written and published, we believe, at the request of the Scots Board of Police, completes the list of his works, so far as we have been able to learn.

The person of Dr Cullen,—we speak of him only in his advanced years,—though striking, and not unpleasing, was by no means elegant. His countenance was expressive, and his eye was remarkably lively and penetrating. His figure was tall and thin, and he had a remarkable stoop about the shoulders. In walking, he had a contemplative look, and did not seem much to notice the objects around him; but in conversation he was animated, attentive, polite, and instructive in an uncommon degree.

Though generally occupied, during five or six hours, almost every day, in visiting patients, or in dictating prescriptions and directions for those who consulted him by letter from a distance, besides having to deliver two public lectures of an hour each, five days of the week for nearly six months every year, sometimes four lectures daily for a considerable period towards the close of the session, that he might complete his courses; yet, whether in public or in private, Dr Cullen never appeared embarrassed or in a hurry, but was always collected and at ease, devoting himself entirely to the present subject, as if he had nothing else to occupy his attention. He was always sociable and cheerful, and ever ready to enter upon the serious subject of the hour, or to discuss the ordinary occurrences of the day. At night, when the labours of the day were over, he enjoyed a private party at whist, for sixpence a corner, even in his latter years, with as keen a relish as if he had no serious employments to think of; and no man more delighted in, or contributed towards, the temperate hilarity, and rational yet amusing conversation of a social supper-party, in which he frequently indulged.

Such is the imperfect view we have been able to collect, of the life and character of a first-rate luminary of the university of Edinburgh, for which we are chiefly indebted to *Hints and Anecdotes relating to his Life*, published by the late James Anderson, LL. D. in a periodical work entitled *The Bee*, about ten months after the death of Dr Cullen. We have been informed, that a more extensive memorial of his life was prepared, many years ago, by a respectable member of the university of Edinburgh, well qualified to do justice to the subject, and was intended to have been published; but, having been communicated for revisal and correction to another person, who was more especially able to supply dates and family circumstances, it was never returned to the author. (KK)

CULLODEN, Battle of. This battle, memorable for being the last fought on British ground, and highly important in its consequences to the peace and security of these kingdoms, happened on the 16th of April 1746, on a moor, about a mile and a half south from Culloden House, and nearly five miles south-east from Inverness.

The success of Charles since his first landing, though occasionally obstructed by dissensions among his friends, had hitherto been extremely flattering to his hopes. Arriving in Scotland with only seven followers, his little army rapidly increased as it advanced; and in a short time became so formidable by its numbers, as to inspire terror into the commander of the king's troops, who, instead of attacking him at Corryarak, as he intended, marched northwards to Inverness, and thus left the low country open to his incursions. Accordingly, Charles now abandoning the fastnesses of Lochaber, advanced into the centre of the country, entered Perth, and proclaimed his father king. From Perth he proceeded to Edinburgh, which he also entered without opposition, and repeated the same ceremony. Meantime, Sir John Cope, finding it dangerous to return from Inverness by the Highland road, on account of the approach of winter, marched his troops along the coast to Aberdeen, and from thence conveyed them by sea to Dunbar. On hearing of their approach to the capital, Charles advanced to meet them, and defeated them with considerable loss in a pitched battle near Prestonpans. In consequence of this victory, he was joined by a few of the Scottish nobility, at his return to Edinburgh; from which place, after some delay, occasioned by a fruitless correspondence with the northern chieftains, he proceeded southwards, making an irruption into England, and spreading alarm and devastation almost to the gates of the capital.

But being now threatened on all sides by the royal army, and harassed by the importunities of his followers, he was compelled to retrace his steps, without effecting any thing. Though pursued by the king's forces, he reached Carlisle, without once coming in contact with them, except at the village of Clifton. After reinforcing the garrison of Carlisle, he entered Scotland by Dumfries, and proceeded to Glasgow, and from thence to Stirling. The garrison of this place refusing to submit, afforded him an opportunity of gathering a few more useless laurels; for Hawley, the commander of the king's troops at Edinburgh, advancing westward with the view of relieving the place, was met by Charles near Falkirk, and defeated with great slaughter. But this was the last of his triumphs; for, immediately after, the Duke of Cumberland assumed the command. Having collected the scattered remains of the battle of Falkirk, and joined to them some regiments lately arrived from the Continent, he instantly set out to meet the rebels, and offered them battle, on the very spot where they had so recently triumphed. By the advice of his generals, though contrary to his own inclination, Charles declined the offer, and retreated immediately with great precipitation to Crieff. Here he separated his troops into three divisions; one, commanded by himself, proceeded north to Inverness by the Highland road; another, under Lord George Murray, marched by the coast road; the third division, which was the smallest, took a middle road, by Braemar, which led them to their own country. The Duke followed them for some time; but, after arriving at Perth, he halted there a few days, both with the view of allowing the reinforcements which had lately arrived from the continent to join him, and in order that he might have an opportunity of consulting with the friends of government at Edinburgh respecting the best mode of terminating the war.

He set out from Perth on the 20th of February 1746, and, following the coast road, reached Aberdeen on the 27th of the same month. As the state of the weather prevented him from advancing farther at this time in pursuit of the rebels, he merely sent onwards a few detachments to occupy certain posts to the westward, which might afterwards facilitate his progress, and continued during the month of March with the great body of his army in the neighbourhood of Aberdeen. During this period of inaction on the part of the king's troops, the rebels were busily employed. They had got possession of Fort George and Fort Augustus, and were actively employed in the siege of Fort William. They had defeated Lord Loudon in Sutherland, and had compelled him and President Forbes to take refuge in Skye. They had surprised a number of posts occupied by the king's troops in Athol; and had even cut off a detachment of the Duke's army which was stationed in the village of Keith. But the season now beginning to open, they were compelled to call in their scattered forces, and to prepare to meet the Duke of Cumberland, who left Aberdeen on the 8th of April, and advanced westward to the Spey, without encountering the least opposition.

When the royal army came in sight of the river, they discovered the Duke of Perth on the opposite bank with a considerable force, and seemingly prepared to resist their passage. Upon observing this, the Duke of Cumberland, for greater security, and for better effectuating his purpose, immediately formed his army into three divisions, and crossed the river at three places, about half a mile distant from each other. The Duke of Perth, however, without waiting to oppose any of the divisions, upon seeing the king's troops approach the river, instantly drew off his men, in obedience to private instructions, and retreated westward to join Charles in the neighbourhood of Inverness. The main body of the royalists followed them leisurely; but some companies of grenadiers, with some light horse, and a few Argyleshiremen, who were more active in the pursuit, overtook their rear before it had quitted the town of Nairn, and a slight skirmish ensued. The rebels, however, still continued their retreat, closely followed by this detachment of the king's troops, and were upon the point of having a more serious rencounter with them at a place called the Loch of Clans, about five miles west from Nairn, when Charles unexpectedly arrived with some troops to their assistance; upon which the pursuers were in their turn compelled to retreat, and join the main body of their army, which encamped the same evening on a plain to the west of Nairn. It appears that Charles, upon receiving intelligence of the near approach of the Duke of Cumberland, had that morning left Inverness with part of his troops, and had ordered the rest to follow him to Culloden-moor, where he intended to offer battle to his enemies.

This resolution of the young prince must appear altogether rash and unaccountable, whether we consider the state of his army, weakened by the absence of numerous detachments employed in the service formerly alluded to; or the situation of the place, which was drawing him away from his resources; or the nature of the ground, which is peculiarly favourable for the operations of regular troops; or, above all, the happy opportunity which he had already deliberately lost, of opposing them at the passage of a rapid river. But whatever might be his motives, certain it is, that next morning he drew out his forces on Culloden-moor, in the expectation that the Duke of Cumberland would leave Nairn that day to meet him. After waiting till past noon, and no enemy appearing, it occurred to him that the royal army might be engaged in celebrating the Duke's birth-day, and consequently would not begin their march till the following morning. He accordingly ordered the men to quarters, and instantly summoned a council of his officers. At this meeting, after considerable difference of opinion, it was determined to make a night-attack upon the Duke's camp at Nairn.

This scheme, which in its details was extremely plausible, seemed to be still more advisable from a consideration of the temporary relaxation of discipline, which, it was probable, would exist in the king's army in consequence of the festivity of the preceding day. This plan, however, so specious in itself, and so opportunely devised, failed completely in the execution, and placed the rebels in far worse circumstances than they were previous to the attempt.

This failure was partly owing to that general insubordination common to all irregular troops, and which had always prevailed to a great extent in the rebel army, but which was, on the present occasion, greatly increased by the hardships which they suffered from want of pay, and regular supplies of every kind; partly to the length of the march, and the short time which could be allowed for performing it; and partly to the extreme darkness of the night, and the necessity they were under of leaving the common road, in order to avoid the houses which lay in their way. The result of all which was a considerable loss of time in commencing the march, and a still greater difficulty in getting on, after the line was put in motion, occasioned by the weakness of some, the desertion of others, the badness of the roads, and the want of unanimity among the chiefs themselves, respecting the expediency of the measure itself. In such circumstances, failure was quite inevitable. While they were yet three miles from Nairn, two o'clock, the hour of the proposed attack, was past. The near approach of dawn, and the beating of a drum in the enemy's camp, now convinced the most sanguine that the project ought to be abandoned, or, at least, that surprise was impossible. Nothing remained, therefore, but to retreat to Culloden; which they did without the least molestation on the part of the enemy, and in much shorter time than they advanced.

Whether this scheme of a night attack would have ultimately succeeded, even if these obvious causes of failure had not occurred, is extremely doubtful; for we find, that the Duke of Cumberland, though ignorant of the details of the plan, especially of that part of it which consisted in attacking him on the south side, was completely informed, by means of spies, of the approach of the rebels, and had made preparations accordingly. Upon hearing, therefore, of their retreat, he drew out his army at break of day, and advanced westward in pursuit of them. The rebels, oppressed with hunger and fatigue, had reached Culloden nearly about the time the Duke began to move from Nairn. But so distressful was their condition, and so overpowering the calls of nature, that, in spite of their perilous situation with regard to the enemy, they no sooner arrived at their former ground, than they immediately dispersed in different directions,—some fainting with fatigue, lay down on the heath to rest themselves, others betook themselves to the woods, others to the villages around in quest of food, and some went even so far as Inverness for the same purpose. While his troops were in this state of disorder and inefficiency, news was brought to Charles at Culloden-house, that the Duke's army was in full march towards him. There seemed to be now no alternative but to fight, even in his present unfavourable circumstances, or to give up the cause as lost. Charles chose the former. Having rallied his troops in the best manner possible, he drew them up on the moor, about a mile and a half south from Culloden-house. The arrangements for battle were made by Sullivan, quarter-master-general, in the following order: He formed the whole, with the exception of a small body of reserve, into two lines; the first consisting of eleven, and the second of nine regiments. The Athol regiment occupied the right of the first line; and on their left, in regular succession, were formed the Camerons, the Appins, the Frasers, the Macintoshes, the united regiment of Maclauchlans and Macleans, Roy Stewart's regiment, Farquharson's, and the three Macdonald regiments, viz. Clanranald, Keppoch, and Glengary. The second line was composed of the following regiments, viz. two battalions of Lord Ogilvie's regiment on the right; and to their left, two battalions of Lord Lewis Gordon's regiment, two battalions of Glenbuckets, the Duke of Perth's regiment, Lord John Drummond's regiment, and two regiments of Irish piquets. The reserve consisted of Lord Kilmarnoch's regiment of foot guards, and the remains of Lord Pitsligo's and Lord Strathallan's horse. On the right of the first line was a troop of horse guards; and on the left of the second line a troop of Fitz-James' horse. The cannon was placed in the centre and on the flanks of the first line. Lord George Murray commanded the right, and Lord John Drummond the left, of the first line. The command of the second line was entrusted to General Stapleton. Charles stationed himself on a small eminence behind the right of the second line.

The spot selected for the engagement was remarkably well chosen, being as favourable to the rebels as the nature of the ground would admit. Immediately south from them was a square enclosure of stone, which extended to the banks of the Nairn, the northern wall of which covered their right flank. In their front the moor was uncommonly marshy and soft; and on their left, though at considerable distance, were the woods of Culloden-house.

In this condition were the rebels when the royal army came in sight, about mid-day. The Duke of Cumberland, upon seeing them drawn up in battle array, commanded his troops to halt, and formed them upon a plan similar to that of the enemy. His first line consisted of six regiments, in the following order, viz. the Royals on the right; on their left Chomondley's regiment, Price's, the Scots Fusileers, Munro's, and Burrel's. The second line consisted also of six regiments, viz. Howard's, Fleming's, Ligonier's, Blyth's, Sempil's, and Wolfe's. Blakeney's, Battereau's, and Pulteney's composed the reserve. On the right of the first line were stationed the Duke of Kingston's regiment of light horse, and a squadron of Lord Cobham's dragoons; and on the left, Lord Kerr's regiment of dragoons, and two squadrons of Lord Cobham's horse. Two pieces of cannon were placed between each battalion in the first line; and three pieces between the first and second battalions on the right and left of the second line. This line was drawn up in such a manner, that the centre of each regiment was opposed to the interval between the regiments in the front line. The Earl of Albemarle commanded the first line, Major-General Huskison the second, and Brigadier Mordaunt the reserve. The Duke of Cumberland placed himself between the first and second line, in the front of Howard's regiment.

When the two armies came in sight of each other, they were about three miles distant. The king's troops, however, after making the necessary arrangements, immediately advanced towards the enemy, and when the front lines approached within 500 or 600 paces of each other, a smart cannonade commenced on both sides. The wet ground in front of the rebels, formerly alluded to, now proved extremely harassing to the royal army. Their heavy cannon sunk into the soft mossy soil, and several regiments, especially Wolfe's, which occupied the left of the second line, were standing above the ancles in water. To remedy this inconvenience, the whole line made a movement in advance, till it reached firmer ground; and as the moor on the left of the second line still continued marshy, Wolfe's regiment was ordered to form on the left of the first line, and to front to the north, by which means it was prepared to fire upon the flank of the rebels if they advanced from their present position. While this movement was making on the left of the line, the Duke of Cumberland observing that the left wing of the rebels stretched considerably beyond his right, ordered two regiments from the reserve to advance and form upon the right of each line, viz. Pulteney's on the right of the Royals, and Battereau's on the right of Howard's.

These arrangements being completed, the cannonade, which had never ceased on the part of the rebels, was renewed by the royal army with increased activity and dreadful effect. Every where in the opposite ranks were seen the destructive ravages of the royal artillery; while the cannon of the rebels, being ill-directed and ill-served, made no impression on the king's troops. The Duke observing this, ordered the cannonade to be continued, in the expectation of compelling the rebels to advance to the attack, by which means they would lose their present advantageous position, and expose their right flank to a destructive fire from Wolfe's regiment. His expectation was soon realized. The Macintoshes, unable any longer to support the galling fire of the artillery, broke from the centre of the first line, and advanced against the regiment opposite them. They were followed by the four regiments to their right, and the Maclauchlans and Macleans on their left. The Macintoshes, who were a little in advance, having met with a heavy fire of musketry from the Scots fusileers, which were opposed to them, immediately inclined to the right, which caused the whole right wing of the rebels to come down upon Burrel's and Munro's regiments. These regiments, however, continued firm, and received them with a very heavy fire of musketry, and cannon loaded with grape-shot.

In spite of this warm reception in front, and a still more destructive fire from Wolfe's regiment on their flank, the rebels continued to advance, and rushing forward sword in hand, cut their way through the opposing ranks, and pushed on to the second line. Sempil's regiment, which occupied the left of this line, was now destined to support the impetuous shock of the whole right wing of the rebels. Nor were they unequal to the difficult task imposed upon them. During the attack they had advanced a few paces from the second line, and upon seeing the rebels break through the first line, they prepared to receive them with their front rank kneeling and presenting. The remains of Burrel's and Monro's regiments retired behind the battalions on their right, and the rebels, after closing their ranks, rushed forward with more than their usual impetuosity. Sempil's regiment, however, remaining calm and unmoved, allowed the rebels to approach within a few paces of their front rank; and when they had almost reached the points of their bayonets, they opened upon them a dreadful fire, which brought the greater number to the ground, and caused the remainder to fall back. A few, desperate and furious, still pressed on and made a fruitless attempt to break through the lines opposed to them, but were received on the bayonets of the front rank.

The regiments on the left wing of the rebels did not advance at the same time, or charge with the same impetuosity as those on the right. Having gradually approached the king's troops, and sustained a regular fire without shrinking, they gave a general discharge, and having drawn their swords, were prepared to rush forward after their usual manner. But upon observing the fatal result of the attack on the right, they immediately wheeled about, and retired upon their second line. The cavalry on the right of the king's army, seeing the rebels face about, instantly began the pursuit: but the Irish piquets opportunely advancing, soon caused them to halt, and allowed the fugitives to fall back on the second line. The two lines being now joined, formed a considerable body of men; but their hearts were broken, and their condition altogether hopeless and irretrievable. The Duke of Cumberland, after closing his ranks, advanced upon them with a firm step, and with all the confidence which recent success inspires. The cavalry on the wings of the royal army were eager to pour in upon them. The wall which guarded their right flank was broken down, by which means a body of horse had got in their rear. There was no time for deliberation; no alternative left but to seek safety in flight, or to rush upon certain death. They preferred the former. At first they went off in small parties of four and five. Afterwards the whole separated into two large bodies, one of which directed its course towards Badenoch, and the other to Inverness. The route being now general, orders were issued to pursue, and as there was little disposition in the king's troops to give quarter, the carnage which followed was dreadful. The number of the slain on the part of the rebels has never been accurately ascertained; some rating it at two, and others at three thousand. Most of the chiefs who commanded the regiments on the right wing which made the furious charge were killed, and almost every man in the front rank of each regiment. Charles himself very narrowly escaped from the field of battle; and after wandering for several months among the wilds in the west of Scotland, he was fortunate enough to make good his retreat into France.

The loss on the part of the victors was comparatively trifling, being not more than 300; and no person of distinction fell, except Lord Robert Kerr, second son of the Marquis of Lothian and captain of the grenadiers in Burrel's regiment.

Such was the fatal conclusion of an enterprise which, from its fortunate commencement, promised a very different issue. What would have been the result upon the happiness and prosperity of these realms if Charles had succeeded in recovering the throne of his grandfather, is not for us to determine. The opinions of men on this subject will differ, according to their prejudices, partialities, or political views. It is sufficient for us to know, that whatever might have been the change, it could have contributed little to the power, the wealth, the liberty, and political importance of these kingdoms. (*s*)

CULM, or KULM, a town of Poland, in the Grand Duchy of Warsaw, is situated upon a rising ground on the banks of the Vistula. The town is large, though by no means populous, and has a Catholic college, and five Catholic convents. It was formerly one of the Hanseatic towns, and the extent of its trade was indicated by large warehouses, which were erected by English merchants. Early in the 14th century, its commerce was in a great degree transferred to Dantzic; and though it has since revived at particular periods, yet it has always been annihilated by the different wars with which Poland has been agitated. Culm received from the Teutonic order the privilege of coining money; and after it fell into the possession of Prussia, a military academy for 60 young noblemen was established in the town. At the peace of Tilsit, in 1807, it was transferred to the kingdom of Saxony; but in consequence of the recent conquest of Poland by the Russians, it will probably fall to the lot of some other prince. (*j*)

CULROSS, a royal burgh in Scotland, situated upon the north bank of the river Forth, about 18 miles above Leith, and in that detached part of Perthshire which lies betwixt the shires of Clackmannan and Fife. The name is of Gaelic origin, viz. *Cul*, back, and *Ross*, a peninsula: The whole district of country between the rivers Forth and Tay, formerly went under the name of Ross. This town, though small and irregular, is beautiful in point of situation; one street extends along the shore, and another runs in an oblique direction along a very steep bank, which is wholly laid out in gardens, with fruit trees. At the top of this street are the ruins of the Cistercian Abbey or Monastery, founded in 1217, by Malcolm, Thane of Fife, and immediately adjoining are the remains of the abbey church, dedicated to the Virgin Mary, and to St Serf, who was the tutelar saint of Culross; the first day of July was annually kept as a festival to his memory. Amongst many of the ceremonies performed on that day, the inhabitants rose very early in the morning, and walked in regular procession, carrying large green boughs, accompanied with music. It is somewhat singular that this ceremony is still kept up, though the particular day is changed, and the origin of it entirely forgotten. Part of the abbey church is used as the parish church, and its lofty massive square towers, finished with a keep at the top, is still very entire. In the convent were nine monks of the Cistercian order, and a confessor. Upon the shore, at the east end of the town, there could be traced, till within these few years, the ruins of a chapel, which was known by the name of St Mungo's Chapel; and upon the shore west from the town, is the scite of Dunnemarle Castle, said to have been a strong hold of the Macduffs, Thanes of Fife. Upon the verge of their western boundary, in this castle, according to tradition, Lady Macduff and her children were murdered by order of Macbeth.

Adjoining the abbey church, stands the once magnificent house built by Edward Lord (Bruse) Bruce, anno 1590; from its situation it commands a most extensive, rich, and varied prospect, with the river Forth in the immediate foreground, having all the appearance of a great lake.

This town is now very much upon the decline, many of the houses being uninhabited, and going to ruin. In former times, however, it was a place of considerable trade, having collieries upon the most extensive scale, and carried on with great enterprise and spirit. One of the pits was in the sea, about a mile from the shore, surrounded with a moat of strong mason-work, where the coals were put on board the ships. The water of this pit was drained from the mine by machinery placed on the shore. When King James VI. visited these coal works, he went down a pit upon the shore, from the bottom of which he was conducted to the pit within the sea; when he ascended it, and saw himself surrounded with water, he instantly conceived that there was a plot against his life, and cried out treason: From this apprehension, however, he was soon relieved by his host and guide, Sir George Bruce, who had in readiness an elegant boat to conduct him to the shore. Several years after this, a violent storm destroyed these singular works, and they were never repaired. Previous to this disaster, great quantities of coal were shipped at these collieries for the coasting trade, London, and the Continent. By an act of Parliament, 1663, the Culross chalder of coals was established as the standard coal measure for Scotland. Here, also, the making of salt from the river Forth was at this period carried on to a great extent, there being at least 50 salt pans employed in the manufacture. This town had also the exclusive privilege of making girdles of beat iron, used in Scotland for baking cakes over the fire; about forty girdle-smiths were employed in this manufacture for the supply of Scotland; they had two royal grants of exclusive privilege, the one from King James VI. the other from King Charles II. But the Court of Session, in the year 1727, set aside the monopoly, after which the trade gradually declined, and it is now extinct.

Lord Dundonald, so justly celebrated for his extensive and practical knowledge in chemistry, resided long in the mansion-house at the abbey, which, with the estate adjoining, were his paternal inheritance: He endeavoured to revive the collieries, but met with insurmountable difficulties, to the great prejudice of his fortune: Here he invented and put in practice, upon a large scale, the process of extracting tar from pit coal, while the coal was converted into excellent coak for the manufacture of iron; the many other important discoveries in chemistry made by his Lordship, are well known to the world. We regret to think, however, that these discoveries have been of no advantage to himself in point of fortune, while many of them have been highly beneficial to the public.

All the collieries and works at Culross being entirely laid aside, have quickly accelerated the ruin of the place, and there is now but very little chance of seeing it revive.

Edward Lord Bruce, who built the mansion-house named the Abbey, fell in the fierce and noted duel fought betwixt him and Sir Edward Sackville, in Holland, where they agreed to meet. Lord Bruce requested, that if he fell in the contest, his heart might be sent home, and laid in his tomb in the abbey church. This tomb was opened lately, and there was found a leaden box which inclosed a large silver heart, within which was the heart of Lord Bruce preserved in spirits. The family arms, the words *Edward Lord Bruce*, and a leafless tree, with the appearance of clouds, were engraved on the silver heart, and perfectly distinct. The whole was carefully replaced, and entombed as they originally were.

Culross was erected into a royal burgh in 1588, by King James VI.; and in conjunction with Stirling, Dunfermline, Inverkeithing, and South Queensferry, sends a representative to Parliament, The population of the town and parish is about 1300. West Long. 3° 34′. North Lat. 56° 8′. (R. B.)

CUMÆ, Cuma, or Cyme, is the name of an ancient city of Italy, in the Campagna. It was situated on a lofty rock near the sea, and was founded by a Grecian colony from Chalcis in Eubœa, and from Cumæ in Æolia. Its power and population gradually increased, and Puteoli, and afterwards Naples, owed their origin to the enterprize of the Cumæans. Its favourable situation for commerce, and the fame of its oracle, its sibyl, and its temples, attracted votaries from every quarter. Cumæ, however, at length yielded to the power of the Romans, and from that time it seems to have gradually declined. The more beautiful and healthy coasts of Baiæ, Puteoli, and Naples, attracted from Cumæ its numerous visitors; and so rapid was its decline, that in the sixth century it was reduced to a military position, containing merely a fortress, situated upon a rock. In the 13th century, it became the head-quarters of banditti, and the neighbouring cities found it necessary to complete its destruction. The scite of the ancient Cumæ is now covered with a solitary wood, which is a royal chace, inhabited by stags and wild boars. A range of broad smooth stones here and there, and a few mouldering walls, overgrown with myrtles and vines, are the only vestiges of this great city. The following interesting account of the grotto of the sibyl, is taken from the classical tour of Mr Eustace, the most recent traveller in Italy. It is too interesting to be given in any other words but his own:

"Continuing," says Mr Eustace, "to advance towards the sea, we come to a high craggy rock near the shore. On the top of a precipice stands the castle, erected in the middle ages, on the ruins of an ancient fortress. In the side of this rock are two great chasms; in one, there are several steps leading upwards; the other, which leads downwards, was formerly lined with brick, and seems to have opened into several galleries. This cavern is now called the *Grotto of Sibyl*, and is probably part of that celebrated cavern. The grotto existed in all its splendour in the year 105 of the Christian era, and is described by Justin the Martyr, an author of that period, and represented by him as an immense cavity, cut out of the solid rock, large as a basilica, highly polished, and adorned with a recess or sanctuary, in which the sibyl, seated on a lofty tribunal or throne, uttered her oracles. It may have been stripped of its ornaments, disfigured, and perhaps materially damaged in the reign of Constantine, when the greater temples, and more peculiar seats of Pagan superstition, were demolished as objects likely to encourage and foster the ancient delusions. However, though despoiled and neglected, the cavern still remained entire, till the fatal and most destructive war carried on by Justinian against the Goths; when Narses, the imperial general, in order to undermine the ramparts of the fortress erected on the summit of the rock, ordered his engineers to work through the roof of the cavern beneath, and thus brought down the wall, towers, and even gates of the fortress, into the cavity, which in part destroyed, and in part filled it with rubbish. The grotto, as I have already observed, branched out into various subterranean galleries, alluded to by Virgil under the appellation of *approaches* and *portals*, which furnished the sibyl with the means of forming those tremendous sounds that in the moment of inspiration issued from the depths of the cavern. Of these communications, two only are now visible; all the others, with the body and recesses or sanctuary of the temple, are filled with ruins of the roof, the lining, and the walls." Mr Eustace is of opinion, that very interesting dicoveries might be made in this quarter by excavating the ground; and that from the advantage of sea carriage, the very materials would be sufficient to defray the expence. See Keysler's *Travels through Germany*, &c. vol. iii. p. 142, 143, 3d edition; and Eustace's *Classical Tour through Italy*, vol. i. p. 354—357. Lond. 1813. (π)

CUMANA, Nueva Andalucia, New Andalusia, is one of the governments which form the captain-generalship of the Caraccas. This government is bounded by the sea on the north; by the river Unara on the west; by the Orinoco on the south, excepting those parts where the left bank of that river is inhabited; and in this undefined part of its frontier, the jurisdiction of the governor of Spanish Guiana extends to within cannon shot of the establishments on the north of the Orinoco.

The interior of this government is covered with mountains, some of which have a great elevation. The highest of these, called Tumeriquiri, is more than 5600 feet above the level of the sea. The immense cavern of Guacharo, so famous among the Indians, forms a part of this mountain. It has a majestic situation, and is remarkable for the richness and luxuriance of its vegetation. A considerable river flows from the cavern; and there also issue from it the cries of millions of night birds, to whom it serves as a habitation. These sounds are ascribed by the Indians to the spirits of the dead, who can find a passage to the other world only by sojourning for a time in this gloomy abode. This privilege, however, is granted only to the virtuous, and the period of their detention is proportioned to the extent of their offences. Hence it is the practice of the Indians to repair to the cavern, to ascertain whether their deceased friends have been ranked among the blessed, and if they distinguish their voice, they conclude that some impediment has been thrown in the way of their final liberation. In the mountains of Cumana, but particularly those of Tumeriquiri, there is a stratum about 18 feet thick of limestone and argillaceous earth, mixed with a very considerable quantity of coal. Above this stratum is frequently found another, apparently modern, of sandy earth, which is a mass of shells, quartz, and secondary limestone. At the depth of about 30 fathoms, these strata appear to be of pure limestone. A careful examination, however, will soon detect the quartz, and the limestone now disappears by degrees, till scarcely any thing else but quartz can be perceived. Mines are said to have been successfully wrought in the valley of Neyva; and it has been supposed, that there is a great quantity of gold in the country from Torayena to La Plata. Mines of coal also occur in this province.

Numerous rivers, streams, and brooks, intersect Cumana in every direction. The rivers Neveri and Mansanares, which are small, and have a gentle current, discharge themselves into the sea on the north. Those which flow into the Gulf of Paria, and into the sea on the east, have much longer courses. The Colorado, the Guatator, the Caripa, the Punceres, the Tiger, the Guayuata, discharge themselves into the Guarapicha, which runs into the Gulf of Paria, and is navigable about 80 miles from its mouth. The remaining rivers flow to the south, and join the Orinoco.

But though these natural canals afford the most admirable means for irrigating the land, and transporting its produce, yet the natural fertility of the soil has received almost no aid from the hand of cultivation. From the river Unara to the city of Cumana, the land has considerable fertility; but it is poor and sandy, from the point of Araya for about 25 leagues to the east. It is, however, an inexhaustible mine both of marine and mineral salt. The principal saline grounds are at Araya, and those of the Gulf of Paria or Triste, between the settlements of Iraca and Soro. The lands on the banks of the Orinoco are fit only for pasturing cattle; but all the rest of the government possesses the most surprising fertility. The principal productions are maize, which supplies the want of wheat; yuca root, which affords another kind of bread; cazabe, cacao, sugar canes. The quantity of sugar produced is sufficient only for the consumption of the province; but on an average of four years, from 1799 to 1803, the quantity of cacao exported from the province amounted to 18,000 fanegas, of the weight of 50 kilogrammes each, or 110 pounds avoirdupois.* The most precious trees, the guiacum, the anacardium, Brazil and Campeachy wood, are found even on the coast of Paria. Abundance of shell fish, of various kinds, and the finest flavour, is obtained in every part of the coast. A great quantity is salted, and carried into the interior; and the province of Venezuela alone, is supplied with above 3000 quintals annually.

The principal colonies dependent on Cumana lie on the western coast, as Barcelona, Piritu, Clarinas, &c. In the valley of Cumanacoa, about 12 leagues to the south-west of Cumana, are the tobacco plantations belonging to the king. The tobacco, which is here produced, is so decidedly superior to that which is raised in every other part of Terra Firma, that the cigars made of it bring double the price of any other. The Indian villages of San Fernando, Arenas, and Aricagua, are situated on the most fertile territory in the environs of Cumanacoa. The fertile but uncultivated valleys of Carepa, Guanaguana, Cocoyar, &c. are situated still farther in the interior.

The refugees from Trinidad, who inhabit the coast of the Parian Gulf from the mouth of the Guarapicha to the most northern mouth of the Orinoco, frequently make great progress in cultivation, owing principally to the proximity of the British settlement, from whom they receive at a cheap rate, and even upon credit, all the iron work necessary for their establishments, and to whom they dispose of their commodities at prices far superior to those which prevail in the Spanish ports.

The climate of Cumana is healthy, though it is scarcely ever cool. In the town of Cumana, Reaumur's thermometer stands in July at 23° in the day-time, and 19° during the night, the maximum being 27°, and the minimum 17°. The hygrometer of Deluc indicates from 50 to 53 degrees in the same month, the maximum being 66°, and the minimum 46°.

The governor, who has his residence at Cumana, is appointed for 5 years. He nominates to all the vacant benefices in the administration of the finances; in all commercial regulations, he acts under the orders of the intendant; and in all military concerns, and foreign political relations, he is subordinate to the captain-general of the Caraccas. The principal cities and towns of this province, are the capital Cumana, (see the next article,) Cumanacoa, Coriaco, New Barcelona, and Conception del Pao. *Cumanacoa*, called *San Baltasar de los Arias* by the government, is situated in a valley of the same name, about 14 leagues south-east of Cumana, in west longitude 63° 58′ 35″, and north latitude 10° 16′ 11″. Its climate is good, and its waters have a diuretic quality. It has a population of 4200. *Coriaco*, otherwise called *San Philippo de Austria* in some official papers, is situated on a river of the same name. Its principal production is cotton, which is the best in Terra Firma, and of which it furnishes 3000 quintals annually. A little cacao and some sugar are also raised. The population is 6500. *New Barcelona*, founded in 1634, is situated in west longitude 64° 44′ 30″, and north latitude 10° 6′ 52″, in a plain about a league from the mouth of the Neveri, and on its left bank. It is neither a handsome nor a pleasant town. Its unpaved streets are loaded with mud in rainy weather, and covered with dust in the dry season, and every part of the town is annoyed with the stench of its numerous hog sties. Great quantities of meat were salted here, and exported to the neighbouring islands, particularly to the Havannah and Cuba, at a profit of a hundred per cent. The hides and tallow formed also another article of trade, but it is now much diminished. The Catalonians who reside here, carry on both a legal and an illicit traffic to a great extent. They bring from Trinidad contraband goods, of which Barcelona is the entrepot,

* See Humboldt's *Political Essay on the Kingdom of New Spain*, vol. iii. p. 24.

Cumana.

and from which they are distributed both by sea and land. About four hundred thousand hard dollars are annually exported for this clandestine traffic. The population, which consists of one half whites and the other half people of colour, amounts to 14,000. *Conception del Pao* is 55 miles from Cumana, and contains a population of 2300 souls, who live comfortably on the productions of the soil. The air and water are good, but the heat is excessive, and the inundations frequent. The population of the government of Cumana is estimated at 80,000 souls. (*w*)

CUMANA, the capital of the government of the same name, is situated on a dry and barren soil, about a quarter of a league from the sea, and about 53 feet above its level. It was built by Gonzalo Ocampo in 1520, and is the oldest city in Terra Firma. The river Mansanares surrounds the city on the south and west, and separates the town from the suburbs, which are inhabited by the Guayqueris Indians. The city is much more than four times as large as it was fifty years ago, and the ancient scite of the town has been so crowded with buildings, that the inhabitants have been under the necessity of building on the left bank of the Mansanares, to the west of the Indian suburbs. This new town communicates with the city by a bridge; and in 1803, a church was erected for its particular accommodation. The first street that was laid out was called Emparan, after the governor of that name, who, in the war between 1793—1801, admitted neutral vessels into the harbours in opposition to the order of his superiors,—a resistance which gave prosperity to the province, and was amply rewarded by his Catholic Majesty. The houses are low and slightly built, owing to the sufferings which have been experienced from frequent earthquakes. The earthquake of December 1797, threw down almost all the stone edifices, and rendered the rest uninhabitable. The earthquake of November 1799, produced a variation in the needle of 45°. Humboldt imagines, that these earthquakes are owing to the proximity of Cumana to the Gulf of Coriaco, which appears to have a communication with the volcanoes of Cummucuta, which emit hydrogen gas, sulphur, and hot sulphureous water. The town is defended by a fort situated on a hill, which extends along the eastern side of the city. It is garrisoned by 231 regulars, and a company of artillery. There is only one parish church in Cumana, (excepting the one already mentioned,) which is situated to the south-east of the city, near a demolished fort. There are two monasteries, one belonging to the order of St Dominic, and the other to that of St Francis.

The river Mansanares is so shallow, that it is navigable only for small craft. Merchant vessels anchor upon what is called the Placer, a sand bank, which lies west from the river about a league from its mouth, and opposite to a stream called Bardones. It is, therefore, necessary to load and unload the vessels with the assistance of lighters. The port, however, has the advantage of being well sheltered from inclement weather.

The population of this town consists principally of White Creoles, who are remarkable for their natural abilities, and their attachment to their native soil. Commerce, navigation, the fisheries, and agriculture, are the general sources of their subsistence. An immense quantity of salted fish is shipped to the Caraccas and other neighbouring cities, and also to the Windward Islands, from which they bring back iron implements of agriculture, provisions, and contraband goods. The Catalonians, and some of the Canary Islanders, carry on the chandlery and retail trade. The principal articles of commerce, besides those already noticed, are cacao nuts and the oil which they afford. Medicinal plants, and a variety of aromatic herbs, might form an important article of commerce, if the inhabitants were able to prepare them. Population 24,000. West Longitude 64° 9′ 45″, and North Lat. 10° 27′ 37″. See Depon's *Travels in the Caraccas*, passim; Humboldt's *Political Essay on the Kingdom of New Spain*; Thomson's *Alcedo;* and Peuchet's *Dictionnaire Commerçante de la Geographie*, &c. (*w*)

Cumberland.

CUMBERLAND is the county which forms the north western extremity of England: it is situated between the latitudes of 54° 6′ and 55° 7½′ north, and between the longitudes 2° 13′ and 3° 30′ west from London. Measured in a north-easterly direction, from St Bees-head to Buttern Burn, its length is 58 miles; but if a line be drawn from its north-eastern to its southern point, its length is nearly 80 miles. Its greatest breadth is 40 miles; but this is only in a small part. Its mean breadth in a north-west direction is 30 miles. It is bounded on the east by Northumberland for 51 miles, from which county its dividing limits, with the exception of the river Irthing, for a very few miles, are artificial; and on the same quarter by Durham, from which its dividing limits are entirely artificial. On the west it is bounded by the Irish sea, for the space of 67 miles: on the north by Scotland and the Solway Frith for 30 miles: the Scotch dyke and the river Liddel form the limits between it and Scotland on the land-side: on the south it is bounded by Westmoreland for the space of 48 miles, from which it is partly separated by Ullswater and the river Eamont; and on the same direction it is bounded by Lancashire for 21 miles, from which it is separated by the river Duddon. The whole circumference of Cumberland is 224 miles; and it contains 1516 square miles, or 970,240 acres; of these, it is computed, that the mountainous districts occupy 342,000; that 470,000 are enclosed and under cultivation; but the number of enclosed and cultivated acres is fast increasing; that about 150,000 acres are in low commons, great part of which are capable of improvement; and that the lakes and waters occupy 8000 acres. The form of the county is very irregular; on the west it projects into the Irish sea, with a convexity like a long-hooked beak, the point of which descends to the detached part of Lancashire. It is divided into five wards: Cumberland-ward, Eskdale-ward, Leath-ward, Allerdale-ward above Derwent, and Allerdale-ward below Derwent. The natural divisions are into the low or arable, and the mountainous: Of the mountainous districts, there are two divisions, one of which bounds the east side of the county, and is the highest part of the English *Apennines*: the other division of mountainous district occupies the south-western part of the county, forming high, steep, and craggy hills, of romantic shapes. The first mountainous district is composed of strata of different kinds of stone, and is rich in coal, lead, and lime: the second mountainous district is destitute of these, but affords, in great abundance, the beautiful blue slate which is used for covering houses: black lead is also found in this district. In front of the first mountainous division, a tract of low ground, of considerable breadth, is stretched, partly cultivated, and partly heathy common, which is watered by the Eden, and a great number of small brooks: as this tract approaches

Cumberland.

Carlisle, its extent enlarges, stretching across the county to Wigton, and thence towards Workington, so that it includes nearly the whole northern portion of Cumberland. A strip of cultivated land stretches along the western shore, from two to five miles in width. The general character of this county is that of bleak mountains, naked moors, and wild wastes: there are very few woodlands: the Irthing, Eden, and Caldew, are the only rivers whose banks produce any quantity of natural wood. The climate of Cumberland is very variable, from the circumstances of its having such an extent of sea-coast, and so large a portion of it being occupied by mountains. The lower parts of the county are mild and temperate, the snow seldom lying near the coast for twenty-four hours; while, on the mountains, it may be seen for six or eight months. A very considerable quantity of rain falls all over the county, but especially near the mountains: the season of the year most liable to heavy rain is the autumn. The neighbourhood of Keswick is supposed to be as rainy as any part of the kingdom: the quantity of rain varying, from the observations of seven years, from 64 to 84 inches. The rivers and rivulets of Cumberland are very numerous: the principal are the Eden, the Eamont, the Duddon, the Derwent, the Greata, the Cocker, the Caldew, the Esk, the Liddel, and the Irthing. The Eden rises in Westmoreland, and enters Cumberland at its confluence with the Eamont; it flows into the Solway Frith near Rock-cliffe Marsh, where it forms a very fine estuary: the vales between its banks and the hills vary in breadth from 20 yards to half a mile: they are provincially called *Holm* lands, and are very fertile. The Eamont rises in Kirkstone in Westmoreland, one of the most romantic mountains in England; and passing through the vale of Patterdale to Ullswater, soon afterwards unites with the Eden. The Duddon rises near the shire-stones, which mark the union of Cumberland, Westmoreland, and Lancashire: it runs, during its whole course, through a narrow dell, skirted by mountains and high lands. The Derwent rises among the crags at the head of Borrowdale: its stream is very precipitous, being dashed from rock to rock till it flows into Derwent lake, at the foot of which it unites with the Greata; and after passing through Bassenthwaite water, and flowing through a narrow vale, it is joined by the Cocker at Cockermouth, and falls into the sea at Workington. The course of the Cocker, which springs from a mountain near the black lead mines, is peculiarly beautiful, from the variety and romantic character of the country through which it flows. The Caldew rises on the south side of Skiddaw: its banks are very woody; its vales rich and beautiful, and the quality of its water is thought peculiarly excellent for bleaching: it turns a number of corn and cotton mills. The Esk rises in Scotland, and enters Cumberland at a place called the *Moat*; after which, flowing through a beautiful vale, and passing Longtown in a westerly direction, it falls into the Solway Frith. The Liddel also rises in Scotland, and enters this county at Kirshope-foot; it passes through a wild and romantic country, in a deep and narrow valley, in one part of which the rocks rise to a great perpendicular height, covered with trees and bushes; it afterwards joins the Esk. The Irthing rises on the hills which lie on the borders of Northumberland, and falls into the Eden, near Newby: in some part of its course, the scenery on its banks is very rich and beautiful.

Climate.

Rivers.

The soils of Cumberland are rich, strong loams: these, however, occupy a small part of the county. Dry loams, which occupy a greater portion than any other, nearly one half of the lower districts, or those capable of cultivation, being of this soil: wet loam, and black peat earth, which is in greatest abundance on the mountainous districts, particularly those adjoining Northumberland and Durham: it is also found on moors and commons in the lower parts of the county, lying on a white sand: with this subsoil, it is most particularly ungrateful and unprofitable. In Cumberland, there are a greater number of very small estates than perhaps in any other county in the kingdom: many of them as low as L. 5 a year; and this kind of property does not often exceed L. 50, and seldom reaches L. 100: the generality of these tenements are from L. 15 to L. 30 a year: they are almost universally occupied by the owners. The rental of the largest estate is said to be about L.15,000 per annum. The greatest part of the land is held by customary tenure; which, besides being subject to the payment of the usual fines on alienation, death, &c. are held under the condition of various services, called *boon days*; such as getting and leading the peats of the lord of the manor, ploughing and harrowing his land, reaping his corn, carrying letters, &c. It is supposed that two-thirds of the county are held by this kind of tenure: the remaining part is generally freehold: copyhold and leasehold are rarely met with. The general size of farms is very small; but these small farms are gradually uniting into larger. Farms below L. 100 a year are the most common: scarcely any reach L. 500 a year. The most singular class among the Cumberland farmers, are the "lairds," or "statesmen," as they are provincially termed: they are the proprietors and farmers of the small tenements already noticed: they retain all the honesty, simplicity, and prejudices of ancient times: they cultivate their estates with their own hands, grow or manufacture every thing they need, and keep aloof alike from the increasing knowledge and vices of the age. Leases are very unusual in Cumberland, and never extend beyond seven or nine years. Much land is held on verbal contracts: besides the rent, many services are required of the tenant, such as grinding corn at a particular mill, supplying the landlord's table with a certain number of chickens, &c. Although this county is so very hilly, the roads are excellent: this may partly be ascribed to the easy and full supply of good materials, and to the universal use of single horse carts, which not only save the roads, but enable the farmer to lay a greater weight on the same number of horses: three of these carts are driven by a man, or a boy, or even women and girls: along the coast, more than half the carts are driven by females, generally under 20 years of age. Formerly grazing was more attended to than the raising of corn; but latterly, especially on the rich strong loams, tillage has greatly increased. There is nothing particularly worthy of notice in the agriculture of Cumberland: the native cattle are a small breed with long horns: great numbers of these are reared and sold to drovers, who bring them into the southern counties to fatten, under the name of Cumberland *steers*. The dairies are small, but the butter is of an excellent quality; a good deal is exported. There are two kinds of sheep, one peculiar to the exposed and rocky districts, called the *Hardwicke* breed: they are polled; mostly white, with a few black spots, with fine small clean legs; they are well adapted to their situation: they are rarely covered or overwhelmed in storms of snow, as they not only gather together in such circumstances, but keep stirring

Soil and Agricultural state.

Cumberland.

about, by which means they tread down the snow and keep above it. The other kind of sheep are the black-faced, coarse woolled, heath sheep, the flesh of which is of a most delicate flavour. Of the manures used in Cumberland, the only one requiring notice as peculiar to this county, is mussels: these are laid on the land in the neighbourhood of Ravenglass, at the rate of five or six cart loads per acre: they are found in great abundance on the lands adjoining the coast. It has been accidentally discovered on the estate of Lord Muncaster in this county, that sea-sand will destroy moss, but it is not used as a manure.

Manufactures.

Manufactures are not extensive or numerous in Cumberland: the principal are the spinning and weaving of cotton into calicoes, corduroys, and other articles. Cotton spinning was first introduced at Dalston, from which place it has extended to Carlisle, Warwick-bridge, Corby, Comersdale, and a few other places. There are small manufactories of checks and coarse linens in some of the market towns. Cotton printing is carried on at Carlisle on a pretty large scale. At Whitehaven and Egremont, there is a manufacture of sail cloth. There are also a few paper-mills, and a manufactory of coarse earthen ware near Dearham. On the borders of the Derwent, above Workington, are the Seaton iron works, which employ several hundred men. They were erected in 1763. They consist of two blast furnaces for melting iron ore; a mill for the rolling and slitting of bar iron, and a double forge for refining and drawing it; a foundery with various small furnaces, for casting cannon and iron work of all kinds; a mill for boring cannon, cylinders, and many other contrivances suitable to the nature of the manufacture. The exports of this county consist principally of coals from Whitehaven, Workington, and Maryport, to Ireland. In 1566, there was but one vessel belonging to Cumberland that was of 10 tons burden; now there are upwards of 300 from 60 to 120 tons employed in the coast trade alone. In 1566, the whole exports consisted of a small quantity of herrings and cod fish, and the only thing imported a little salt. In 1582, on a survey being taken of the ships and mariners within this county by the Earl of Lincoln, who was at that time Lord High Admiral, the vessels amounted only to twelve, and one of which was of 80 tons burden; the mariners and fishermen were 198. In 1607, Workington was the principal seaport. Criminals sentenced to banishment in Ireland, were shipped from hence. Besides coals, butter, bacon, and hams are also exported, most of which, and likewise some salmon, go to the London market.

Commerce.

Mountainous scenery.

To the admirer of the grandeur and beauties of nature, the mineralogist, and the antiquarian, Cumberland is a very interesting county. The mountains of Cumberland not only afford very extensive and grand views, but many of them are of singular structure, and immense elevation. As we enter the county at the south-west corner, a high conical-topped hill, with smooth and cultivated sides, affording an extensive view from its summit, presents itself. It is called Blackcomb. On the southern borders of the county are Hardknot and Wrynose; and on the margin of Bassenthwaite lake the roots of Skiddaw lie. This majestic mountain is nearly 3500 feet in perpendicular height above the level of the lake. The prospect from its summit is uncommonly varied and extensive. On one side the Irish Channel, on the other side the German Ocean, may be seen. On a clear day, the shipping in the Solway Frith, though at the distance of upwards of fifty miles, may be distinguished. On Bouscale Fell, to the north-east of Skiddaw, is a spacious lake of water so completely enclosed by a ridge of rocks, that, during months in winter, the rays of the sun never reach its surface. On Souter fell, which is nearly 900 yards high, extraordinary phenomena appeared towards the middle of the last century, which gave rise to much speculation, and created no small degree of alarm and apprehension. Appearances of armed men, on foot and horseback, were seen. They moved in regular troops along the side of the fell, describing a kind of curvilinear path, their first and last appearance being bounded by the top of the mountain. From the description given of these phenomena, they seem to have been similar to the spectre of the Brocken, an aërial figure that appears among the Hartz mountains in Hanover, and were probably produced by the same cause. Saddleback, on the western side of Souter fell, seems to have been in a volcanic state; and a lake on the upper part of it, from the lava and burnt stones found in its neighbourhood, is conjectured to have been the crater. The views from the summit of Saddleback are very extensive; but it is scarcely possible to look down its sides without experiencing the most awful and shuddering sensations. The height of this mountain is 3324 feet. In the vale of Wanthwaite, which stretches at the bottom of the southern declivity of this mountain, is a singular piece of scenery. A castle of great antiquity, and in ruins, seems to stand on the summit of a little mount. It shews a front of various towers, with lofty turrets and ragged battlements. Even the galleries, the bending arches, and the buttresses, may be traced. Such it appears when viewed from the widest part of the dale; but as it is approached its figure changes, and it is discovered to be a massive pile of rocks, disunited from the adjoining mountains. The inhabitants called them the castle rocks of St John, and believe them to be an artificial but antediluvian structure. The rocky chasm of Borrowdale opens from the centre of the amphitheatre, that binds the head of Derwent-water. "Dark caverns yawn at its entrance, terrific as the wildness of a maniac, and disclose a narrow strait running up between mountains of granite, that are shook into almost every possible form of horror, and resemble the accumulations of an earthquake, splintered, shivered, piled, amassed." "This region of desolation furnishes a succession of such romantic and picturesque scenes, as can hardly be equalled in the island. Near the entrance of the pass into Borrowdale, is a detached mountain called Castlecrag, the views from which are very peculiar. On one side, every thing indicates civilization and repose, and fills the mind with soft and mild emotions; the vale and lake of Keswick, with villages, seats, and farm-houses. On the other side every thing is terrific, and bespeaks the convulsions of nature; immense rocky mountains huddled together in the most singular arrangement, as if emerging from, or returning to, the wildest chaos; rock rests over rock, and mountain triumphs over mountain." In one of the recesses of Borrowdale, and nearly opposite Castlecrag, is a gigantic rock called the Bowder Stone. It lies almost hollow, resting on some fragments of rock. Its veins are exactly similar to those of the adjoining precipice, though it is not easy to conceive how, if it ever formed part of it, it could have reached its present position. Its length is about 31 yards, and it is computed to weigh nearly 1800 tons. Helvellyn, which lies to the south-east of Borrowdale, is partly in Westmoreland. Its height is 3324 feet. On account of its being at a greater distance from the sea, the snow lies longer on it than on Skiddaw. The pros-

Cumberland.

pect from its summit is very extensive. Crossfell is the highest part of the mountains on the east side of Cumberland. Its height is 3390 feet. The prospect from it is calculated to include a diameter of more than 100 miles, and to comprehend great part of six counties. On it occurs the singular phenomenon called a *helm-wind*. Its appearance is that of an enormous white cloud resting on the summit of Crossfell, which it covers like a *helmet*, whence it takes its name. When it first begins to gather, a black stripe of cloud is seen continually flying off, which is called the *Helm-bar*, because, while it continues, the wind is thought to be confined, for as soon as the black cloud is dispersed, it rages with great violence. While the helm is perfectly motionless, the bar is in continual agitation. It is observed, that the storms of wind, which rise on one side of the mountain, seldom affect the other; and what are called in this county *shedding winds*, generally blow on the contrary side of Crossfell from opposite quarters to the *helm-winds*. While the latter blow, the atmosphere is extremely chilly, but its warmth is restored by the rain, which generally terminates this phenomenon.

Lakes

Of the lakes in Cumberland, which are very numerous, the most celebrated for their scenery are Derwent-water, or Keswick lake, and Ullswater. The form of Derwent-water is very irregular, somewhat approaching to the oval. It extends from north to south about three miles and a half; its breadth is about one and a half; its greatest depth is 20 feet, in a channel running from end to end, probably formed by the river Derwent. The two extremities of this lake afford prospects of a very opposite character. From the southern extremity, an immense chasm opens in the midst, the entrance of which is divided by a rude conic hill; beyond, broken mountainous cliffs soar one above another, overshadowing the dark and winding deeps of Borrowdale. From the northern extremity, Skiddaw shows its vast base, and, "bounding all that part of the vale, rises gently to a height that sinks the neighbouring hills, and opens a pleasing front, smooth, verdant, and smiling." On the southern side of the lake is the cataract of Lowdore, which consists of a series of cascades, tumbling over an extent of precipitous rocks, which are partly concealed by the trees that grow on the numerous fissures. The height of the fall is nearly 200 feet. Nearly opposite to this fall, small islands are said to have been occasionally seen floating about, appearing for a few days, and then becoming invisible for weeks or months, and sometimes for years. The waters of this lake are frequently agitated with what is called a *bottom wind*; they swell in high waves even when there is a perfect calm; the motion is from west to east, and continues sometimes only for an hour, sometimes for a whole day. Ullswater, which is partly situated in this county and partly in Westmoreland, is not nearly so beautiful as Derwent-water, but it possesses a much larger proportion of dignity and grandeur. Its shape is somewhat like the letter Z, only the angles are less acute. Its length is 9 miles; its breadth little more than one. A vast rock projects in its second reach, which reduces its breadth to less than a quarter of a mile. The character of the first reach, as viewed from the foot of Dunmallet, is nearly that of simple grandeur. The characteristics of the left shore of the second reach, are grandeur and immensity. The finest perspective in the lake, is that which is seen as the road descends into Gowbarrow Park, which can scarcely be equalled for alpine sublimity. But the most various and extensive view that the shores of Ullswater exhibit, is gained from an eminence near Glencoyn woods. This view comprehends both the reaches, and though not the most picturesque, is certainly the most grand. The sublimity of the view of the last reach, is much lessened by the rocky islets with which it is spotted, which do not accord with the tremendous mountains which hang over the entrance of Patterdale, nor with the massy and broken cliffs on the eastern shore. The rocks of this lake are celebrated for echoes exceedingly grand and impressive. Char, gwinniard, and trout of a peculiar species, of the weight of 30 pounds and upwards, are caught in Ullswater.

Mineralogical productions.

Cumberland is very rich in mineralogical substances, which are, however, so numerous, that they can be only briefly mentioned in this article. Limestone is found at Overend, with ammonitæ, entrochi, and asteriæ in it; and at Gilsland with a great variety of marine exuviæ. Marble of different colours, and finely veined, free from cracks, and admitting of a high polish, is met with at Kirkoswald and other places. The lead mines of Aldston Moor are rich in a great variety of substances of the calcareous genus. In the mines situated between this place and Keswick, spar, crystallized in hexagonal prisms, terminated at one end by a pyramid, is not uncommon. Sulphate of lime, compact, foliated, and crystallized in the latter state with the crystals disposed like a cock's-comb, is met with at Newbiggen. In this place it is imbedded in red argillaceous marl, between strata of sandstone, the upper solid and fine grained, the under loose and coarse. In some places, below the strata of gypsum, there is a thin bed of decayed wood. Most of the sand-stones contain mica, and silvery mica is met with in the quarries on the Peterel. Soap rock has been found semi-indurated, at Hill-top and St John's, and solid at Borrowdale and other places. The lead mine at Northend, and some of the mountains, afford asbestos. Quartz crystals of the yellow kind, little inferior to the Brazilian topaz, occur in Aldston Moor; and small garnets have been met with in the neighbourhood of Keswick. Trap, whinstone, loadstone, and argillaceous schistus, are very common. The last forms the summit of Skiddaw. Kaolin is found at Barrock, near Nebsteps; and tripoli has been discovered on the banks of Ullswater in gravel beds; and in coarse clays, jet, bearing a fine polish, is sometimes met with in the rocks on the Irthing. It is wrought into toys, bracelets &c.

Coal mines.

Coal is very abundant near Whitehaven and Workington. Near the former place, the beds of coal are 9 or 10 feet thick, and dip to the west 1 yard in 8. In various parts, are great bars of stone which cut off the coal. If they bend one way, the coal rises up; if another, it sinks down. The mines are sunk to the depth of 130 fathoms, and are supposed to be the deepest that have been hitherto wrought; the extremity of the principal mine extends two miles from its entrance, and is beneath the sea a considerable way. The coal mines near Workington are not near so deep as those near Whitehaven, generally from 40 to 90 fathoms. The coal lies in seams, divided from each other by intermediate strata; the upper seam is generally 3 feet thick; the second 4 feet; and the third from 10 to 12 feet: they do not work below this seam.

Lead mines.

The principal lead mines in Cumberland are at Aldston Moor, on the borders of Northumberland. The lead ores lie in cracks or fissures, that are never wholly perpendicular, and they always incline downwards from that side where the strata are highest. A considerable proportion of silver is not unfrequently found in the

Cumberland.

ores of lead. The *breaks* that are met with, are generally incrusted with beautiful spar. About 11,000 men are usually employed in the Aldston Moor lead works, and the owners are said to clear upwards of £16,000 per annum.

Copper mines.

Copper ores combined with sulphur, and containing iron and arsenic, are not uncommon; The principal copper mines are near Caldeck, in Borrowdale, and at Newlands. At the last place, the celebrated mine of Goldscarp is situated, from which, in former times, immense quantities of copper were procured. In the parish of Egremont, is one of the most singular mines of iron ore in the kingdom. It lies at the depth of 12 fathoms. The thickness of the seam, which is hard solid metal, is between 24 and 25 feet. It was not much wrought till 1784. Great part of the ore is sent to the Carron foundery. Native Prussian blue is sometimes found in the peat mosses of Cumberland. Oxide of lime, cobalt, antimony, oxide of manganese, and wolfram, likewise occur in different parts of the county.

Black lead mines.

But the most singular mineral production of Cumberland is black lead. The mines are situated at the head of Borrowdale. The black lead lies in the mine in form resembling a tree: the root contains the finest, the branches the worst, and the quality declines as their distance from the stem increases. Sometimes the extremity of the branches appears on the surface of the ground. There are two workings; the lower 340 yards above the level of the sea; the upper nearly 390: the perpendicular height of the former is about 105 yards, of the latter about 30. The black lead is generally embedded in the fissures of a blue rock, and is found in irregular masses. Between the rock and the black lead, there is sometimes a wet *sludge*. In some places in the mines, *sops* or lumps of the mineral are found without branches. In the deepest mine, two veins cross each other; and the lead is richest, and in greatest abundance, at the point of intersection. It is not known when this mineral was first discovered. An act of parliament was made in the reign of George II. to prevent its being stolen, in consequence of the owner of a contiguous part of the mountain having secretly sunk a shaft, and opened a passage diagonally to the mine. At that time, from the words of the act, it seems to have been principally used in the casting of bomb shells, round shot, and cannon balls. In order not to overstock the market, the mines are only opened at intervals for a short period, and while they are wrought, the labourers are watched and examined very narrowly. Over each entrance a house is built, which is occupied by the stewards and workmen.

Mineral waters.

Gilsland Spa, in the vale of Irthing, about eight miles south-east of Bewcastle, is much frequented. The principal spring is strongly impregnated with sulphur, but not so disagreeable to the palate as springs of this kind usually are. At a small distance is a chalybeate spring, and four miles off another impregnated with alum and vitriol. The banks of the river near the Spa are very interesting to the geologist, as the stratification is completely exposed to view. The height is forty yards: The mould occupies six inches; coarse clay tinged with oxide of iron, five yards; argillaceous shiver, two yards; coarse freestone, eight yards; limestone, one yard; black shiver strongly impregnated with alum, one yard; schistus, sandstone, ironstone, and limestone, curiously intermixed, six yards; another stratum of black shiver, from which the sulphureted water issues; and below this indurated argil, called *clunch*. About the year 1695, a patent was granted to some gentlemen for pearl-fishing in the river Irt, near Ravenglass; and one person is said to have obtained as many as he sold in London for L. 800. None are met with now. On the Derwent, a singular mode of catching salmon is practised by persons on horseback, termed *Salmon-hunters;* they carry a spear with three points, with a shaft fifteen feet long. The huntsman plunges into the water, and while at a swift trot strikes the salmon, which, by a sudden turn of his hand, he raises to the surface, and, without dismounting, runs it the readiest way to dryland.

Antiquities.

There are several Druidical and Roman antiquities in Cumberland; of the former, the most remarkable and celebrated is an extensive circular arrangement of rude and unhewn stones in the parish of Aldingham, about three miles from Kirk-Oswald, called *Long Meg and her Daughters*. This monument is nearly 350 yards in circumference: it consists of sixty-seven stones, some nearly ten feet high, and from twelve to fifteen feet in girth. The smallest are only about two or three feet high, and of proportional diameter. They are placed at regular distances on the south side; but on the north, east, and west, between two stones rather larger than the rest, the distances are greater. Without the circle, opposite the south-west, two stones are placed; and about seventeen yards farther off is the stone called Long Meg, which is eighteen feet high, and at its greatest diameter nearly fourteen in girth. It is a freestone, similar to what is found in a quarry a few miles distant. Of the rest, some are flint, and many granite, which must have been brought from a considerable distance. There is no mark of a tool on any of them. What is commonly called the Picts Wall, is the principal antiquity of Roman origin. It runs from the river Tyne on the east, to the Solway Frith on the west. It was begun by the Emperor Adrian, against the incursions of the Brigantes and the Caledonians. At first it was built in the manner of a mural hedge, with large stakes wreathed with wattles. It was repaired by the Emperor Severus, or rather rebuilt with stone, and strengthened by a ditch and a chain of forts. About the year 430, just before the Romans left Britain, this wall was repaired, and rendered still stronger. From Staniwix, a little village north-west of Carlisle, where the Picts' wall crosses the Eden, its remains may easily be traced westward to its extremity at Bulress, a small town on the Solway Frith. From Staniwix it may also be traced eastward for nearly eight miles; but in this space only the foundation of Severus' rampart, and the trench of Adrian, can be discerned. Farther to the east it runs up a high hill; from whence, till it crosses the Irthing and enters Northumberland, it is entire, in some places to the height of five feet, and in others to the height of eight feet.

Cumberland contains one city, 17 market towns, and 112 parishes. The ward of Allerdale is in the diocese of Chester, the rest of the county in that of Carlisle. It sends six representatives to parliament, pays one part of the land-tax, and raises 200 men for the militia.

History.

Most antiquarians are of opinion, that Cumberland, at the time of the Roman invasion, was inhabited by the *Brigantes*. Mr Whitaker, however, maintains, that the *Voluntii* inhabited it as far as Adrian's wall on the north. Its inhabitants were very warlike, and were never completely, and for any length of time, subdued by the Romans. It seems to have been governed by its own princes, after the Romans left Britain, till the 10th century, when, according to some writers, it was

Cumberland. History.

conquered by King Edmund, who granted it to Malcolm, king of Scots. This opinion, however, is controverted by other writers. Mr Pinkerton thinks that Cumberland was conquered by the Scots, and that they possessed it by right of conquest, and not by any grant from the English; and this opinion seems to be confirmed by the circumstance, that it is omitted in Doomsday-book, which it could not have been had it been a grant from England. In 1072, William the Conqueror conquered, or re-assumed the grant of Cumberland, and bestowed it on Ranulph de Moschines. When Stephen set up his claim to the crown, in order to prevent the interposition of the Scots, he consigned to them Cumberland, as well as Northumberland and Durham. In 1154, Malcolm IV. gave up his claim to this county, in return for a confirmation of his claim to Huntingdonshire. From this period till the middle of the 13th century, there were frequent disputes between the Scots and English monarchs respecting their right to it, till, at a conference held at York, Henry III. in full satisfaction of all the claims of the king of Scots, agreed to assign lands of the yearly value of L. 200 within the counties of Northumberland and Cumberland. Notwithstanding this adjustment, there was still a tract between the two kingdoms not immediately subject to either, called *Debatcable Ground.* This was inhabited by a lawless banditti, who invaded and plundered both countries, and, quarrelling among themselves, frequently gave rise to wars between the Scotch and English nations. For the regulation of the Borders, Edward I. appointed a lord warden of the marches; but the banditti still continued numerous, powerful, and beyond the reach or controul of the law: And border depredations were very frequent even in the reign of Elizabeth. James I. in order to extinguish all memory of hostilities between the two kingdoms, prohibited the use of the term *Borders,* substituting in its stead that of *Middle Marches;* but it required almost 100 years after this period to wear off the jealousies and antipathies of the English and Scotch *Borderers* to each other. After Henry II. resumed the grant, the honour remained with the crown till the time of Henry VIII. who created Henry Clifford earl of Cumberland. The title continued in the family of the Cliffords till 1643, when male issue failing, the honour ceased for a time. In 1644, Charles I. created his nephew Prince Rupert Duke of Cumberland; and the title henceforth has been appropriated to one of the royal family.

Population.

The following statistical abstract for this county, is taken from the population-return for 1811:

Number of inhabited houses	24,002
Families that occupy them	28,390
Houses building	130
Uninhabited houses	550
Families employed in agriculture	10,868
——— trade, manufactures, &c.	11,448
——— not included in these classes	6,074
Number of males	63,433
——— females	70,311
Total population	133,744
Population in 1801	117,064
Increase	16,680

Cumberland, Richard.

CUMBERLAND, Richard, was born February 19, 1732, in the master's lodge of Trinity College, Cambridge. His father was a clergyman in Northamptonshire, and grandson of the learned bishop of Peterborough; his mother was the younger daughter of the celebrated Doctor Bentley, and the Phœbe of Byron's Pastoral. At the age of six he was sent to the school of Bury St Edmund's, then under the mastership of the Rev. Arthur Kinsman. There he manifested a great inaptitude to learn. His mind seemed to have no cleverness nor vigour. What was perhaps worse, he was supremely idle; and accordingly he gradually took, and for some time resolutely kept, his station at the bottom of the class. His worthy teacher, however, remonstrating with him on his indolence and want of spirit, and reminding him of what was expected by his maternal grandfather, succeeded in rousing him to diligence; his natural faculties, which were good, began to unfold themselves; he now entered fairly and heartily on the career of improvement, and very soon became an excellent scholar, rising superior, in some points, to the very ablest of his competitors, and disappointing all the fears which his previous carelessness had created. In his 12th year he was at the head of Bury school. Besides being a proficient in Greek and Latin, he had turned his attention to English poetry wrote verses that might have done honour to a riper age, and even produced a drama entitled *Shakespeare in the Shades,* composed, indeed, almost wholly of passages from that great writer, whom his mother had taught him to relish and to reverence, but put together with wonderful ingenuity and skill.

From Bury he was transplanted to Westminster school, then taught by Doctor Nichols, under whose tuition he advanced rapidly in classical attainments, not, however, without some aberrations of conduct; for on one occasion he left the Abbey in the time of divine service and joined a parcel of boys for the purpose of insulting the Quakers at their devotions; and on another, gave in to his master an exercise in Latin verse, every syllable of which he had stolen from Duport, and imposed upon the unsuspecting Doctor. He continued to court the muses, and at this time wrote a translation in blank verse of a part of Virgil's Georgics, which is not at all discreditable to his powers. He was also permitted to go sometimes to the theatre, where he had an opportunity of seeing Garrick, and of cultivating that taste for the drama with which his mother had first inspired him.

After spending two years at Westminster, he was admitted at Trinity College, Cambridge, where, though at first he had the misfortune to be put under the care of unfaithful tutors, and had nobody almost to direct and counsel him, he led a very regular and studious life; read poets, historians, philosophers, every thing that came in his way, with indiscriminating avidity; composed a little in English, but declaimed a great deal in Latin, of which language, in all its varieties, he was anxious to make himself completely master; mortified his body and endangered his health, that he might improve his mind; allowed himself only six hours sleep, and lived almost entirely on milk, while he gave himself to the study of mechanics, hydrostatics, optics, and astronomy, and those other branches of physical science, a profound knowledge of which was necessary to prepare him for passing through his academical trials with eclat; worked all his propositions, formed his minutes, and even thought and meditated in Latin, in consequence of which he acquired an extraordinary and enviable facility in expounding, solving, and arguing in that language; made such progress, that at the age of seventeen he *kept an act* against one whom he describes as a "blackbearded philosopher" and a "finished mathematician," and after a long and obstinate contest, defeated him, receiving unusually high compliments from the moderator who presided on the occasion; and at the end of a scrutiny peculiarly trying and severe, but terminating completely in his favour, he first took his *bachelors* degree, and then obtained a distinguished place among the *wranglers* of his year. The intense application by which these honours were gained, had nearly cost him his life; for six months he laboured under a rheumatic fever, which threatened to prove fatal; at length, however, by the skilfulness of his physician and the attention of his friends, he recovered from his indisposition, and was enabled to resume his studies. To restore his health, his father took him, along with the rest of the family, to reside in York. There he seems to have spent his time without pleasure and without improvement. He hunted in the morning, danced in the evening, wrote silly verses to employ his fancy, but did nothing that could either inform or invigorate his understanding. From this scene of trifling he was happy to escape, and hastened as soon as possible to college, where he had already acquired so much honour, and expected to gain still more by the continuance of his exertions. His natural dispositions, and the example of his ancestors, had directed his views to the clerical profession, and he was on the eve of obtaining a Fellowship in a manner the most creditable and advantageous, when a different path of life was opened to him, on which he entered without sufficient reflection, and on which he seems to have looked back at the end of his career with little else than feelings of bitter regret.

He received an invitation from Lord Halifax, then president of the Board of Trade, to whom his father had been useful during a canvass in Northamptonshire, to be his private confidential secretary. This invitation was not altogether welcome to himself, but his father and his friends, who anticipated nothing but prosperity and eminence, prevailed upon him to accept of it, and he accordingly plunged into the world of ceremony and politics, having his head full of Greek and Latin, his heart fixed on the college he had left, and little or no stomach for his new occupation. His principal study consisted in reading books upon the colonies, with which he was desired to acquaint himself; and the whole of his business, in copying a few private letters to civil officers abroad. All this, along with the inconveniences of London lodgings and London hours, did not prevent him from preparing, with his accustomed diligence, for the approaching election at Trinity College. His preparation was complete, and his efforts were successful. He had formidable rivals to contend with, and some prejudices in a higher quarter to encounter; but his abilities overcame all opposition, and after a difficult struggle, he obtained the Fellowship which had been the object of his ambition. This was an excellent opportunity for returning into the line of life which he had abandoned, but it is probable that the brilliant prospects which had dazzled his father, were now equally enchanting to the son; and he persevered in his course. He went back as soon as possible to his situation under Lord Halifax.

About this time he made his first literary offering to the press. It was a church-yard elegy, entitled *St Mark's Eve*, in imitation of Gray's, composed during some of his college vacations; but it excited little interest in the public, and procured as little gain to the publisher. As Lord Halifax wrote all his own dispatches, and as there was otherwise not a great deal of official duty for Mr Cumberland to perform, he betook himself to literature and the muses. He was bold enough to project a heroic poem on the History of India. But after having been at considerable pains in collecting materials for the work and making some progress in it, he desisted; and in this he acted wisely, if we may judge of the whole from the specimen he has given in his memoirs. Though he continued to read and write incessantly, yet he had leisure enough to reflect on his situation, to feel its dependance and its gloom, and to meditate a retreat. His father, however, removing to the vicarage of Fulham in his neighbourhood, and thus restoring him to those domestic enjoyments, the loss of which he had all along deeply regretted, he was prevented from taking that step; he remained in town during the hours of business, and spent the rest of his time at home. About a mile from Fulham, was La Trappe, the residence of the famous Bubb Doddington, to whom he was introduced, and with whom he became a frequent guest.

Lord Halifax having resigned his office in administration, and Mr Cumberland being ousted of course, he went to spend the summer at Eastbury, Mr Doddington's seat in Dorsetshire, where he saw a great many fashionable and amusing characters; and while he listened to the conversation, and admired the wit of others, did not forget to exhibit the powers of his own genius; having written a small poem, which was read by Mr Doddington to his company, and in which he attempted to console his patron on the event of his resignation, and complimented his host for his politeness and his politics. On his return from Dorsetshire, he offered himself as a candidate for a lay-fellowship, then vacant in Trinity college, and by the kindness of his friends he succeeded; but celibacy being an essential qualification for the place, he did not hold it long. It was about this time that he wrote his first dramatic piece. The subject, the Banishment of Cicero, was unfortunate for a tragic plot; the execution was not much better than the subject; and, accordingly, though strongly recommended by Lord Halifax, it was rejected by Garrick as unfit for representation. The publication of the play justified the refusal of Garrick, but did not prevent his Lordship from resenting it long and warmly.

In February 1759, having obtained a small establishment as crown agent for the province of Nova Scotia, he married the only daughter of George Ridge, Esq. of Kilmiston, in the county of Hants,—a young lady of great worth and beauty, by whom he had several children, and with whom he lived affectionately and happily. In the following year, upon the death of the king, Lord Halifax, who had previously re-assumed his office of First Lord of Trade, was appointed Lord-Lieutenant of Ireland, and Mr Cumberland went along with him to fill the post of Ulster Secretary. Before he set out, he wrote in blank verse, and published without his name, a poem on the King's accession, addressed to his Majesty, and containing the common-places about princely virtues, wise government, and public happiness. In Dublin Castle his situation was neither pleasing nor profitable. He was entrusted with the regulation of the Lord-Lieutenant's establishment; and, notwithstanding all his skill and economy, the expences were pushed by his lordship's pride and extravagance to L. 20,000, while there was only L. 12,000 to meet them. In his own subordinate sphere he himself was not much better. The fair income of his office was about L. 300 *per annum*, which came considerably short of his extraordinary expenditure; and his mind was too high or too honest to have recourse to the usual means of aggrandizing his fortune. He would accept of no gratuity which could be interpreted as a bribe; and had even the fortitude to refuse the rank of baronet, when it was offered by his patron as a mark of approbation. This refusal, however, contributed to weaken his interest with Lord Halifax, and to render successful the attempts of more complying and sycophantish competitors for favour. His lordship's change of sentiment and conduct towards him soon appeared; for when he received the seals of Secretary of State, he declined, on some idle pretence, to appoint Mr Cumberland to the place of Under Secretary, which he naturally expected, and respectfully applied for; so that for the sacrifice of all his original prospects, and the faithful and irksome services of ten or eleven years he held a place (that of crown agent for Nova Scotia) of only L. 200 a-year. His situation, however, was bettered by the kindness of the Earl of Hillsborough, First Lord of Trade and Plantations, who made him Clerk of the Reports, and thus secured him an additional annual revenue of L. 200. The duties of his new office were neither numerous nor burdensome, and left him abundance of leisure for his favourite studies. He produced an opera, called *The Summer's Tale*, of whose merit he himself entertained no high opinion; but which, on account of a few good songs inserted in it, with some original music furnished by Drs Arne and Arnold, and the vocal powers of the performers, had a run of nine or ten nights in moderate houses, and without opposition. It was purchased and published by Dodsley; and though he gave a liberal price, he did not complain of his bargain.

In the course of the summer Mr C. paid a visit to his father, who was now Bishop of Clonfert, in Ireland; and having returned to England in October, he produced, in the following winter, his first comedy, entitled the *Brothers*, at Covent Garden. It brought advantage to the theatre, and reputation to the author; and soem complimentary lines to Garrick, who was in the house the first night of the performance, introduced him to that celebrated actor, and laid the foundation of a lasting friendship. In the ensuing year, having paid another visit to his father at Clonfert, there, in a small unfurnished closet, with no avocations to call away his attention, with no interruptions to disturb his fancy, and with no prospect from his window but that of a turf-stack, he began to plan and compose his comedy of the *West Indian*, which immediately after his return to England he finished, and gave to Garrick, by whose assistance it had been improved, and under whose auspices it was ushered into life. Its popularity was deservedly great. It was performed with high applause for eight-and-twenty successive nights, and realised for the author a very handsome sum of money. His success encouraged him to go on in dramatic composition, and play after play came from him, perhaps with injudicious rapidity. He stepped aside, however, from this course, to vindicate the insulted memory of his grandfather Bentley, who had been attacked and abused in a pamphlet written by Bishop Lowth, which he did with some spirit and success, in a Letter addressed to that dignitary. The publication of the West Indian established Mr Cumberland's reputation; he was now accounted one of the most distinguished ornaments of English literature; his company was courted by men of taste and talents; he became a member of the famous club which was composed of Johnson, Reynolds, Burke, Goldsmith, M'Pherson, Garrick, and other eminent characters; and continued to enjoy their intimacy and respect. His comedy of the *Fashionable Lover* was very favourably received by the public. In point both of moral and of diction, it is perhaps superior to the *West Indian*, and at least supported the fame which this charming production had procured for him. The *Choleric Man*, another comedy, brought forward the following season, was not quite so popular as the three which preceded it, nor has it ever enjoyed the same eclat; it is, however, possessed of great merit, and reflects credit on the powers of its author. Having made a tour to the lakes in Cumberland in company with the Earl of Warwick, he took the opportunity of a few leisure days at Keswick, to write an irregular *Ode to the Sun*, which was published in 1776, along with another Ode addressed to Doctor James, by means of whose celebrated powders one of his children had recovered from a dangerous fever.

After writing several more plays, among which was the tragedy of the *Battle of Hastings*, that failed in exciting any interest, or in adding any thing either to his fortune or his fame, a brighter scene appeared to open upon him, in consequence of the death of Lord Halifax. Lord George Germain, who succeeded in the colonial department, promoted him to the secretaryship of the Board of Trade, and not only did this in the most friendly way, but shewed him every mark of kindness and attention. It is pleasant to observe, that Mr Cumberland's promotion seems to have gratified him, chiefly because it afforded him the means of giving a more ample and liberal education to his children, whose welfare was ever nearest to his heart, and who repaid his kindness by their affection and their duty. At the request of Lady Frances Burgoyne, he drew up the defence of the unfortunate Robert Perreau, which was adopted by his counsel Mr Dunning, and proved the means of saving the prisoner's life. So great indeed was his reputation at this time as a writer, that Dr Dodd applied to him for his good offices, which he would very readily have granted, had not the painful and hopeless task devolved on his friend Dr Johnson. It deserves to be recorded for the credit of Mr Cumberland, that it was chiefly, if not wholly, through his exertions, that Sir George B. Rodney received that naval command, which he executed with so much honour to himself, and so much advantage to the country. In 1780, he was sent on a private diplomatic mission to the court of Spain, in order to negociate a peace, for which he previously discovered there was a favourable opening. But the project failed. Whether the failure was owing to insincerity on the part of Spain, or to mismanagement on that of the British ministry, certain it is that Mr Cumberland did not receive the treatment to which he was entitled from his employers. The promises made to him before he set out were not fulfilled—his bills upon his bankers were dishonoured by the treasury—in consequence of this, he was arrested at Bayonne on his way home, by order from his remittancers at Madrid, while labouring under the violence of a fever—he had incurred so much expence, though abundantly economical, as to put him under the necessity of selling every acre of his hereditary estate, in order to liquidate his debts—all the applications that he made for remuneration and redress, were received with coldness, and treated with neglect—and there is reason to believe, that a long and interesting memorial which he addressed to Lord North, setting forth his grievances, and claiming relief, was never even honoured with a perusal;—that it produced no effect, is a melancholy and indisputable fact. On the overthrow of Lord North's administration, and the dismissal of the Board of Trade, under the regulations of Mr Burke's bill, Mr Cumberland was set adrift, having a compensation allotted to him, better indeed than what he received for his Spanish claims, but not amounting to more than a half of what was taken from him. Reduced by these unfortunate events to narrow circumstances, he put his family on a corresponding establishment, and took up his residence at Tunbridge Wells. Here he seems to have spent his time very agreeably, devoting himself as formerly to his books and his pen, and enjoying the society which the place and neighbourhood afforded.

Soon after his return to England, he published a work in two volumes, entitled, *Anecdotes of eminent Painters in Spain*, in which he communicated some curious and interesting information on a subject that was little known, and gave a catalogue of the paintings in the royal palace at Madrid, which the Spanish monarch permitted to be drawn out at his request, and transmitted to him after his return. Some time after, he produced the *Observer*, a collection of original essays on various topics, favourable to religion, morals, and literature. That part of it which gives a review of the literary age of Greece, and a history of the Athenian stage, is particularly valuable; it has received high encomiums from the most competent judges, and deserves the attention of every classical scholar. From the translations which it contained of the fragments of the Greek comic writers, the learned author of the Pursuits of Literature concluded, that Mr Cumberland was the only man in the kingdom equal to the translation of Aristophanes. The Observer, of which two editions were published in the two first years, extends now to six volumes, and is considered as a standard book. The next work of any consequence that Mr Cumberland attempted, was an epic poem in eight books on the death of Christ, and entitled *Calvary*. He began the composition of it in winter, and rising every morning some hours before day-light, soon completed it at the rate of more than fifty lines a day. It did not meet with a very favourable reception in the stately and expensive form of a quarto. The author complained of the ungrateful and unbrotherly neglect of his cotemporaries. He gave the king's librarian a copy to be laid at his majesty's feet; but it does not seem to have elicited one spark of royal favour. He was consoled, however, by anticipating the praises of posterity to a work of which his own opinion was sufficiently exalted. And, indeed, before he died, his publishers boldly ventured on a new edition, in a more portable size, and he had the happiness to know that *Calvary* was both purchased and admired beyond what he had allowed himself to expect. Amidst the various subjects which occupied Mr Cumberland's pen, that of religion was not neglected. He studied and he wrote upon it with good effect. His chief production in this way was entitled, a *Few Plain Reasons for Believing in the Evidences of the Christian Revelation*, a treatise which is tolerably well reasoned, and may be read with considerable profit.

When the volunteer system prevailed in the country, he stepped forward and gave his services for the public cause; first as major commandant, and then as lieutenant colonel, to which rank he was promoted, though he had not a single acre of ground in the county. He took great pleasure in drilling his men, who were much attached to him, and whose soldierlike conduct he has commended in his Memoirs. These *Memoirs* of himself were undertaken at the suggestion and request of some friends, who probably conceived that such a work might be a means of bettering his fortune. He began them at the close of the year 1804, finished them in September 1805, and published them immediately. A second edition was soon called for, and to this he added a supplement, for the purpose of stating facts which he had omitted to mention, and making some remarks on Mr Hayley, the Edinburgh reviewers, and others who had offended him by their animadversions. Mr Cumberland's Memoirs have been much read. They are highly entertaining and not uninstructive, contain a good deal of egotism, but more of benevolence, and abound in lively and most characteristic representations of the literary and political characters of his time. The copy right was sold by him for L. 500. He attempted another epic poem on another sacred subject. It was called the *Exodiad*, having for its subject the history of Moses from the period of his leading the Israelites out of Egypt, to his death upon Mount Horeb. He was assisted in it by Sir James Bland Burges, who drew out the plan, and took his share in the execution. The merits of this work are far from being eminent. The most unsuccessful, perhaps, of all Mr Cumberland's literary undertakings was the London Review, which was published quarterly, had superior pretensions to honesty and candour, and endeavoured to support these by annexing to every article the name of the critic who had written it. It very soon died, if indeed it could ever have been said to live. Without the awful and mysterious hypothesis of a tribunal of learned men, who solemnly deliberated upon the books reviewed, and labouring under the depressing influence of open and individual responsibility, it was destitute of spirit and of interest: tame and cautious in itself, and deriving no importance from the oracular wisdom of its authors, the public would have nothing to do with it; and accordingly it was soon given up as an unprofitable concern.

In the latter period of his life, Mr Cumberland endured a variety of afflictions. The loss of his wife, the bad health of his favourite daughter and of her husband, the disgrace unjustly inflicted on one of his grandsons on board a ship, the gradual disappearance of those who had been the companions of his youth and the friends of his maturer age, the failure of his literary pursuits, and the consequent pecuniary difficulties with which he had to struggle,—all these things bore heavy on his mind, and occasioned many a pang. Yet he bore his misfortunes with much patience, and was often chearful amidst them all. Even when he was thus situated, and had seen no fewer than fourscore years, the fire of poetical genius still burned with some degree of vigour. And however much it is to be regretted, that a more appropriate task did not occupy the last days of Mr Cumberland, than the composition of an indifferent play, yet such is the fact that he was actually engaged in completing the now unfinished drama of Demetrius, when death carried him off the stage of this world. He breathed his last, after a sudden and short illness, at the house of Mr Henry Fry, in Bedford Place, Russel Square, on the 7th of May 1811, in the 80th year of his age. A funeral procession took place, and his body was deposited in a spot nearly at an equal distance from the remains of Dryden and Addison.

The preceding account of Mr Cumberland has been drawn up from his own *Memoirs*, from the biographical sketches of him published after his decease, and from incidental notices which have occurred to us in the course of our reading. Our limits do not permit us to give a particular character of all the productions of his pen, but the following is a tolerably accurate list of them, so far as they have come to our knowledge.

I. Theology. 1. Sermons. 2. A Few Plain Reasons for believing in the Evidences of the Christian Revelation. 3. Fifty of the Psalms of David rendered into English metre.

II. Heroic Poetry. 1. Calvary, or the Death of Christ, in blank verse. 2. The Exodiad.

III. Dramatic Works published during his life. 1. The Banishment of Cicero, in 5 acts. 2. Caractacus. 3. The Summer's Tale, originally an opera, and then cut down into an after-piece of 2 acts. 4. The Brothers, a comedy. 5. The Fashionable Lover, a comedy. 6. The West Indian, a comedy. 7. The Choleric Man, a comedy. 8. Timon of Athens, altered from Shakespeare. 9. Note of Hand, or a Trip to Newmarket. 10. Mysterious Husband. 11. The Battle of Hastings, a tragedy. 12. Box Lobby Challenge, a comedy. 13. Calypso, an opera. 14. The Impostor, a comedy. 15. The Widow of Delphi, or Descent of the Deities, a comic opera. 16. False Impressions, a comedy. 17. The Carmelite, a tragedy. 18. The Natural Son, a comedy. 19. The Dependant. 20. Days of Yore. 21. Word for Nature. 22. First Love, a comedy. 23. The Jew, a comedy. 24. Country Attorney, a comedy. 25. The Arab, a tragedy. 26. Wat Tyler, a comic opera, objected to by the Lord Chamberlain, and new modelled and produced under the title of the Armourer. 27. The Clouds, translated from the Greek of Aristophanes, and incorporated into the 6 vol. edition of the Observer. 28. The Sailor's Daughter. 29. Wheel of Fortune, a comedy.

IV. Posthumous Dramatic Works in two volumes 8vo. Vol. I. contains the Sibyl, or the Elder Brutus, a tragedy. 2. The Walloons, a comedy. 3. The Confession. 4. The Passive Husband, a comedy. 5. Torrendal, a tragedy. 6. Lover's Resolutions. Vol. II. contains, 1. Alcanor, a tragedy. 2. The Eccentric Lover, a comedy. 3. Tiberius in Capreæ. 4. The Last of the Family, a comedy. 5. Don Pedro. 6. The False Demetrius, (unfinished).

V. Fugitive Pieces. 1. Verses on the King's Accession. 2. A Poem after the manner of Goldsmith's "Retaliation." 3. Verses on the bust of the present Prince of Wales. 4. An irregular Ode addressed to the Sun. 5. Ode to Dr Robert James. 6. Lines to the Earl of Mansfield. 7. St Mark's Eve, an elegy.—With a great number of small pieces which it is not worth while to detail.

VI. Novels. 1. Arundel, 2 vols. 2. John de Lancaster. 3. Henry, 4 vols.

VII. Controversial. 1. A Letter to the Bishop of Oxford, (in vindication of Dr Bentley.) 2. A Pamphlet on the Bishop of Llandaff's proposal for equalising the Revenues of the English Hierarchy.

VIII. Miscellaneous. 1. Curtius rescued from the Gulph. 2. A Sketch of Lord Sackville's character. 3. The Observer, 5 vols. 4. Anecdotes of eminent Painters in Spain, with a Catalogue of the Paintings in the King's Palace at Madrid. 5. Memoirs of Himself, 4to. and with a Supplement in 2 vols. 8vo. 6. Preface and Articles in Tipper's Review. (τ)

CUNONIA, a genus of plants of the class Decandria, and order Digynia. See Botany, p. 215.

CUPANIA, a genus of plants of the class Octandria, and order Monogynia. See Botany, p. 199.

CUPAR, a town of Scotland, in Fifeshire, is situated in the middle of the county, on the banks of the river Eden, at its junction with the Mary-burn. The ground in the immediate neighbourhood is alluvial, and elevated above the level of the sea about forty feet; but on the north and south it rises to a considerable height, and greatly circumscribes the view from the town. The fields along the banks of the Eden are often enveloped with mist, whose influence is pernicious to the potatoes in autumn, and to cabbages and other vegetables in winter. The town is but poorly supplied with water. There are few springs, and the wells dug in the argillaceous strata form *hard* water, highly impregnated with earthy salts.

The town consists of three streets, besides a number of lanes and detached buildings. The Crossgate, or principal street, runs from north to south, is broad, well-aired, and contains many substantial well-finished houses. Here the weekly markets are held, and here also are the best frequented inns. The Bonygate joins the north end of the Crossgate, and stretches to the west. It is a little narrower than the former street. The New-street, or St Catherine's, is nearly on a line with the Bonygate, joining its east end. It has been built according to a regular plan, and the houses are elegant and commodious.

The town of Cupar can boast of few interesting objects of antiquity. Its castle, of which no vestige remains, was once a place of considerable strength. In its neighbourhood, there was a convent of Dominican or Black Friars. On the high ground to the east of the town stood the church of St Michael. The steeple connected with the present church, is a very handsome building, and is a great ornament to the town. It was built, in part, by the prior of St Andrew's in 1415, and finished by Mr William Scot, who was for many years minister of Cupar, and who died in 1642.

The parish church is a very plain building, possessing no external decorations, unless we consider the porch as such, which was lately added. It is not sufficient for the accommodation of the inhabitants of the parish. The town-house contains chambers suited to the purpose of public meetings, but has a very mean exterior. The county-rooms, which were added to the town-house nearly thirty years ago, are now forsaken, more elegant accommodation being provided in the buildings in the New-street, for the noblemen and gentlemen of the shire to hold their public meetings, balls, &c. The plan for the new county-rooms was drawn by Mr Gillespie, and executed by subscription under the management of a truly patriotic magistrate, John Ferguson, Cupar Fife.

Esq. of St Catherine's, the present provost of the burgh. Adjoining to the county rooms, an inn has been built by tontine; and it was proposed to terminate the new street with the prison ordered for the town by a late act of Parliament. A plan was made of the prison, corresponding in style with the other buildings in the street. Objections were urged against the propriety of placing it so near the river, and at such a small elevation above it, suspicions being entertained that dampness would prevail and injure the health of those confined. The party who urged these objections soon forgot them, after they had frustrated the efforts of those who wished to make the public buildings of the town subservient to ornamental purposes. The prison is now erecting on the south side of the river, nearly upon its margin, a few feet higher than its banks, and several feet lower than the situation formerly proposed. With regard to the plan of the building, we have to regret that more pains have been taken to decorate the walls, than to make the cells either healthy or comfortable.

The inhabitants of the town are in general healthy, and frequently long-lived. Few instances of derangement or deformity occur. Their principal employment is the manufacture of linen. There are also manufactures of leather, candles, ropes, brick and tile. There are three branches of Edinburgh banks for the accommodation of the merchants: the Bank of Scotland, the British Linen Company, the Commercial Bank, together with the Fife Bank. The poor are well attended to, being supported by donations from the revenue of the burgh, and by voluntary contributions made at the doors of the church.

The church of Cupar is a collegiate charge, and its meetings are well attended. There are likewise meetings for Episcopals, Antiburghers, and those connected with the Relief.

The children of the town have good opportunities for receiving instruction, as there are excellent schools, under the patronage of the magistrates, and the inspection of the clergy. All the useful branches of education are taught with ability and success. There is a public library, well-stocked with books in various branches of literature and science. And we may mention, as connected with the literary history of the town, that the printing-office of Mr Tullis has produced editions of Horace, Sallust, Virgil, Cæsar, and Livy, revised by Dr John Hunter of St Andrew's, which, in point of typography, do great credit to the Cupar press.

Cupar is a royal burgh of very ancient date. It is governed by a provost, three bailies, a dean of guild, thirteen guild counsellors who choose one another, and eight trades counsellors or deacons, elected by the eight corporations. The revenue of the burgh is about L. 500 a year. Here a weekly market is held, and also seven fairs. Being the head burgh of the shire, the public business is here transacted, and the courts of law and taxation are held. Population of the town 4000. (J. F.)

Cupar Angus.

CUPAR, or COUPAR, generally called CUPAR-ANGUS, is the name of a town and parish in the county of Angus or Forfar. Before the Reformation, the parish of Cupar-Angus formed only a part of the parish of Bendochy, which lies about a mile to the northward, across the river Isla. Many years after its erection into a parish, the lairds of Kithock retained a servitude over it; every possessor of a farm and grass-house was obliged to pay a proportional quota of money or victual to their boatman, in name of freight, for transporting the people to the church of Bendochy. The parish is nearly five miles and a half long, and varies from one to two miles in breadth. It contains about 2500 acres. A narrow ridge runs along two thirds of the parish of a light gravelly soil; the rest, in general, appears to be loam or clay, and the neighbourhood of the town is full of vegetable mould. The greater part of the parish is enclosed, and the crops chiefly raised are wheat, barley, oats, turnips, and potatoes. Land rents from L. 2 to L. 7 per acre, but the latter sum is only given for land in the immediate vicinity of the town. There is one farm in the parish of 500 acres, but in general they run from 50 to 120 acres.

The town lies towards the west end of the parish, and contains, by the last return, 2100 inhabitants. They subsist chiefly from the profits of agriculture, though there is a considerable manufacture of coarse brown linen, to the extent, at present, of 200,000 yards per annum. The town is divided by a rivulet which rises about five miles to the south west, and discharges itself into the Isla, two miles and a half to the northwest. This rivulet forms the boundary between Perth and Forfar shires, as it runs through the town. Cupar-Angus was a Roman station during the expedition of Lolius Urbicus, according to Chalmers in his *Caledonia*. The east side of the camp appears to be pretty entire, and measures 400 yards in length. The south side was levelled about 30 years ago, and is now under tillage. The prætorium was about the centre of the camp, as it is the highest ground within it, and commands a view of the whole. On or near the site of the prætorium, was founded the abbey, by Malcolm IV. in 1164, the year before he died. It was erected at the request of Walthoef, abbot of Melrose, for monks of the Cistertian order. Boece says, that in his day they were remarkable for their pious and blameless lives. The abbey is completely demolished, except a small fragment, overgrown with ivy, which appears to have been a part of the south-west corner. The greater part of the town formerly was built of the stones which composed it; and the foundation is so completely defaced, that it is now extremely difficult, if not impossible, to trace the form of the building itself. The church must have been in the form of a cross; but if we might hazard a conjecture, the abbey formed three sides of a square, with cells around for the monks.

A steeple was built by subscription about fifty years ago, on the site of the regality prison; and, in 1767, the Earl of Moray, the proprietor of the abbey lands, presented the town with a bell, which was placed in it.

The town lies about twelve miles and a half northeast from Perth, and fourteen and a half north-west from Dundee, near the middle of the estate of Strathmore. The whole of the parish, except the lands belonging to the Hon. Archibald Stuart, son of the late Earl of Moray, about 130 acres, lies in the county of Perth.

The following is the population of the parish at four different periods:

1755	1491
1793	2076
1801	2416
1811	2590

The population of the town in 1801 was 1960, and in 1811, as already stated, 2100. *

CURACOA, or Curassou, one of the West Indian islands. It is situated in the Caribbean sea, to the north of Terra Firma, and of the province of Venezuela, from the coast of which province it is not more than twenty leagues distant. This island lies in latitude between 12° and 13° north, and in longitude between 60° and 70° west. It is in itself little more than a bare rock, extending from nine to ten leagues in length, and somewhat more than three in breadth. It produces some sugar, tobacco, wool, and leather. It is comparatively of little consequence, however, in respect of cultivation or pasturage; it derives its importance altogether from its subserviency to commerce.

When the Portuguese recovered from the Dutch that part of Brazil which had been originally taken from them, the republic of Holland would have lost all footing in the new world, but for a few small islands which they still had in possession, particularly this of Curaçoa. That island had been held by the Spaniards since 1527; from them it was taken by the Dutch in 1632. What principally induced the Dutch to undertake this conquest, was a desire to procure for themselves the facilities which it would afford for the prosecution of an illicit trade with the Spanish main. It was, besides, in the vicinity of the island of Jamaica towards the north, of St Domingo on the north-east, and of the smaller Antilles towards the east, in all of which directions accordingly it was yet farther practicable to prosecute a gainful commerce. Soon after the period alluded to, crowds of Dutch ships, strongly built and well armed, were seen pouring into the island, where they were in the practice of touching either for intelligence or for pilots, and then to proceed chiefly to the Spanish coasts with a view to trade. This they were able to force with a strong hand, being not only armed but even manned with choice men, whose bravery was animated by the interest which they had individually in the success of their operations. They had each one of themselves a more or less considerable share in the cargoes on board, which it was therefore their resolution to defend at the hazard of their lives against all attacks of the *guarda-costas*. In progress of time, some change took place in the manner of conducting this forbidden intercourse. Curaçoa itself became an immense magazine, to which the Spaniards came in their boats with the view of exchanging their gold, their silver, their vanilla, their cacao, their cochineal, their bark, their leather, their mules, for negroes, linen and woollen cloths, silks, India stuffs, spiceries, laces, ribbons, quick-silver, articles of iron and steel, or whatever other commodities were brought into the numerous storehouses formed within this island, either from Europe or the East Indies, or any other parts of the world. In this traffic, the Dutchman had the advantage of disposing of great quantities of various sorts of goods, which were the mere refuse of warehouses and mercers shops, and which had grown unfashionable, and therefore unsaleable every where else. Though vessels were, in the manner alluded to, constantly passing from the Spanish coast and returning, this did not prevent the Dutch vessels from proceeding to the creeks and bays of the Spanish coast. There was a reciprocal feeling of wants, a mutual contribution of labour and of exertions for supplying them, which produced a just degree of activity around these shores. It seemed as if there were an actual competition on foot between nations, rivals in commerce, and equally covetous of wealth. The substitution of register-ships in place of the galeons, caused afterwards some relaxation in this twofold communication; but it may be expected, that it will always revive when the state of foreign relations is in any respect such as to prevent the direct supply of the Spanish coast with those articles of provision that are indispensible to it.

The trade of Curaçoa, even in times of peace, was said to be annually worth no less than £500,000; but in time of war the profit was still greater, for then it becomes the common emporium of the West Indies, affording a retreat to ships of all nations, and at the same time refusing to none of them arms and ammunition for their mutual destruction. The intercourse with Spain being at such times interrupted, the Spanish colonies have scarcely any other market whence they can be well supplied either with slaves or goods. The French came hither to buy the beef, pork, corn, flour, and lumber which were brought from the continent of North America, or exported from Ireland. And besides the other articles of its own native produce, the salt works of the island, which are good and valuable, afford a considerable supply of this article to the English islands and the colonies on the continent.

It was in ships from Curaçoa, together with those of Carthagena and Porto-Bello, that almost all the negroes that were sent to Peru used formerly to be conveyed to it. This was a very considerable branch of traffic, the Spaniards often taking off not less than 1500 slaves at a time. This trade has diminished from the period that the English settlers in Jamaica took part in it; and were allowed, so to speak, to do it publicly; but a compensation was found in the traffic which succeeded in European goods. It is impossible to estimate the quantity of goods of this description, which, though contraband, the two towns just named carried off every year from Curaçoa, or which the Hollanders themselves distributed throughout the opposite coast of Venezuela, as well as in the river Hache and in New Andalusia. The sugar prepared in Curaçoa, and the tobacco grown there, as well as the wool, leather, and other produce of the island itself, made one part of the cargoes which were taken in return by the ships that brought those commodities when setting out again for Europe. These, however, would have afforded no adequate inducement to draw thither the number of ships that used annually to visit this island; and its trade must have quickly come to an end, had not the rich merchandize of Spanish America abundantly compensated the pains that were thus taken for furnishing the magazines of the island with an ample and constant supply of European goods. This traffic, so sure and so rich, has been, for the most part, carried on in five or six large vessels, which were constantly at sea, and in progress from one coast to the other; those concerned in the management of it being so well aware of its importance, that no more time was allowed on any occasion for remaining in port than while the vessels were unloading and taking in the fresh cargoes, which were always in readiness for them at the island.

In consequence of the lucrative traffic which thus originated between the Dutch settlers of Curaçoa and the Spaniards, it became the policy of the former to

Curaçoa. prevent the ships of adventurers from entering into their ports, and to refuse purchasing the booty which those determined pirates drew from the Spanish nation. This apparent misunderstanding with the freebooters, was not, however, in any respect really prejudicial to the interests of the merchants of the island; for when an opportunity offered, the vessels of the pirates were dispatched to St Thomas's, a Danish settlement, whither they were followed by ships provided with money or goods, with which to purchase, or to receive in way of barter, their illicit cargoes.

Curaçoa has been accustomed, especially in times of war between Great Britain and France, to supply all the southern coast of St Domingo with provisions. It at the same time took off the produce of that island, which, even at the state of improvement to which the colony, while in possession of the French, had advanced, could not but be very considerable. French armed vessels from the windward islands, regardless of the length of the passage, went thither in crowds during the continuance of war, because they could there find every thing necessary for the equipment of their vessels, often the commodities of the Spanish main, always those of Europe, which are in these parts in universal use. English privateers but rarely appear in those seas.

The trade between Curaçoa and St Domingo afterwards fell greatly off, in consequence as well of the supplies which the latter island obtained from other parts, as of the commotions which arose in it. Every commodity, without exception, landed at Curaçoa, while it remained in possession of the Dutch, paid one per cent. port duty. Dutch goods were never taxed higher, but those shipped from other European ports paid nine per cent. more. Foreign coffee was subjected to the same tax, with the view of promoting the sale of that of Surinam. Every other American product was subject only to the payment of three per cent. but with the express stipulation, that it was to be conveyed directly to some part of the republic. The Dutch Company trading to the Indies never itself engaged in any commerce at Curaçoa, but was contented with the duties accruing from whatever was brought into the island. The caprice of those appointed to the collection of these taxes, was too much made the measure of their amount, foreigners of course being always those who were most molested. The various civil officers whom, for this or other purposes, the company maintained here, were very ill organised in respect to the maintenance of the interests of individuals, but they were specially charged to look after those of their employers. The principal, and the highest in credit of these officers, was the fiscal, who at the same time was sole notary of the island, and registered all public acts.

It has been of much consequence for the commerce of Curaçoa, that it has an excellent harbour. Indeed it has two considerable ports, one on the south part of the island and at its western extremity, called St Barbara, the other, and the principal one, three leagues to the south-east of its most northern parts. To this large and excellent harbour the access is, indeed, somewhat difficult, but when once it has been entered its spacious basin affords every convenience and security. It is capable of containing and protecting against all winds, as well as against any hostile force, upwards of 300 ships of the largest size. Any repairs can be conveniently made in it, so that a fleet defeated at sea may find here at once a safe asylum and conveniences for refitting. In the time of war, it is well adapted to serve as a rendezvous for merchant vessels bound to Europe, which, from its situation to windward, may always take refuge in it. It is an excellent station for provisions. In the war of 1780, cruisers from this island greatly annoyed the English West India trade, and with such advantage to themselves, that there was a balance accounted for by the treasury of about 190,000 francs (about £17,275 sterling,) arising from the duties on the prize-cargoes. Those proceeds had been invested on mortgage for the benefit of the company. The port last mentioned is defended by a fortress, skilfully constructed and constantly upheld in proper condition.

Curaçoa, offering in some respects but little temptation to enemies, has been sufficiently exempt from hostile attacks. In 1673, the French having corrupted the commandant of the island, landed on it to the amount of 500 or 600 men. The treason, however, having been discovered, and the traitors punished, the invading troops were obliged to reimbark, without having met with the success that they expected. About five years afterwards, Louis XIV. whose pride had been hurt by this check to his conquering arms, sent out D'Estrees with 18 ships of war and 12 buccaneering vessels to wipe off the stain. But, from the rashness and obstinacy of the admiral, these vessels, when not far from their place of destination, were run aground on Davis's island; and the shattered remains of the fleet having been collected, returned in very bad condition to Brest, without having effected any thing. For a long time after that period, neither Curaçoa, nor the little islands of Aruba and Bonaire, dependant on it, suffered any disturbance.

It was necessary, as a traveller remarks, that one should have been a Dutchman, to think of settling there. Through the industry of the Dutch, however, not only were the advantages indicated which this place might afford in respect of trade, but the face of the country itself was so much improved as to make it, even in that point of view, not altogether undesirable. Through their exertions, the pastures, which formerly furnished a great number of cattle, were converted into plantations for sugar and tobacco; and a soil naturally barren, rendered in a variety of respects productive. In these circumstances, it has, at periods comparatively recent, again attracted the notice of enemies. It was captured by the English in 1798, and afterwards in 1806, by Captain Brisbane, who had upon the occasion three frigates only under his command. The official value of the imports and exports of the island under its new masters was, in 1809, imports L. 241,675, exports L. 316,696; in 1810, L. 236,181 imports, and exports L. 263,996. The principal articles imported from, or by way of, it into Great Britain, were coffee, sugar, rum, and cotton-wool. The following Table contains a list of the principal articles imported into Great Britain during the years 1809 and 1810.

	Coffee.		Sugar.		Rum.	Cotton Wool.
	British Plant.	Foreign Plant.	British Plant.	Foreign Plant

1810	700	29,466	—	—	24	230,770

Curaçoa. The principal towns of Curaçoa are one of the same name, and Williamstadt. The city of Curaçoa is well situated; its buildings are large, convenient, and magnificent; it is full of store-houses and shops, well provided with every species of merchandize, and of all kinds of manufactories. In its port, which, though dangerous and difficult to be made, is abundantly secure, vessels from all parts are continually lying. There is something also done here in the ship-building trade. The entrance to the port is defended by a castle, which, with the city, was in 1714 bombarded, but without success, by the French under the command of M. Caissar. The commanding ship of his squadron was wrecked upon the coast. There is in the city a synagogue for the conveniency of the many Jews by whom it is inhabited, and who are the principal merchants.

In Williamstad, which is considered to be the chief town of the island, or on the opposite side of the harbour, there are scarcely any white inhabitants besides a few merchants. Such as have any lands live upon them, and the public officers and servants of the company live in or near the fort. Houses are built so close to the walls of this fort, that a ladder from the upper stories would be sufficient to get within the walls. A remarkable blunder, also, of the engineer is noticed, who, in building a stone battery, turned the embrasures inwards instead of outwards; while in the front of that battery, which is intended to command the entrance of the harbour, there has been built a range of warehouses, which are not only themselves exposed to the fire of an enemy, but so impede the use of the guns of the fort, that it would be necessary to level them to a certain height before its shot could reach a hostile force. The powder-magazine also was placed at a distance from the fort, and in such a situation as to expose the road or access to it to the fire of any ship coming round on that side. The town, harbour, and fort, might, however, by the use of proper precautions, be rendered in a great measure impregnable to any attacks either by land or from the sea. The inhabitants of Williamstad are a mixture of Jews, Spaniards, sailors, free mulattoes, free negroes, Musquito and other Indians. The native population is become extinct, with the exception of three or four aged people at Curaçoa, and a few persons residing at Bonaire; while of whites, there are hardly half a dozen families who have not intermarried with Indians or negroes on the intermediate coasts. The religious houses of this city are a Dutch reformed church, a Lutheran church, a Roman-catholic chapel, and a Jewish synagogue.

A great deal has been said of the vices, and the disorderly manner of living, which, at former periods, are stated to have been in an extreme degree prevalent at Curaçoa. To the Jews who traded in it were attributed all the rapacity and bad faith, which, in any other instance, have been alleged to be characteristic of this people. The trade of the island in general, it has been represented, was a frightful tissue of piracy and pillaging: while manners were on a similar footing as commerce; libertinism, debauchery, robberies, murders, assassinations, being under no restraint, and no such thing as either justice or any regular system of police known. No respect or deference was paid to any authority subsisting on the island, military, civil, or ecclesiastical. The only formality of marriages was a certificate given by the public notary, and which stood at once instead of civil convention, and of nuptial benediction. The excesses of debauchery, it has been added, to which the people of this island gave way were such, that it was well for them that the air which they there breathed was not of that insalubrious character that it might appear to be, and had sometimes been represented: had the case been otherwise, it must soon have been entirely depopulated. The licentiousness of the negro slaves, owing to various causes, was in full proportion to that of the other parts of the community; while in their case there was a farther and a peculiar subjection to suffering. In the event of a scarcity of provisions, the distress of course fell chiefly on them; and in respect of the absurd principle adopted as to their manumission, which was that of a small fine being paid by the proprietors to government for their emancipation, generally when they were too old to work, they must then either obtain a precarious subsistence by begging, or be exposed to perish from want. CURDISTAN, or KURDISTAN, a country of Asia, comprehending the whole of Assyria Proper, with part of Armenia and Media. In a general view, this country may be considered as bounded on the east by the mountain Coatrus and the river Surokh, which separates it from Irak, Azerbijan, and other parts of Persia; on the west by the Tigris, which divides it from Mesopotamia and Chaldea; on the south by Irak, and on the north by Turcomania. Towards the south it is narrow, scarcely exceeding 100 miles in breadth; but northwards it stretches near 500 miles, from east to west, *i. e.* from the 39th to the 47th degree of east longitude; and from north to south it reaches from about 34° or 35° to from 37° or 38° north latitude. The limits of this country do not appear, however, to have been very precisely ascertained. Indeed, tribes of the people called Curds are found widely dispersed over many parts of the empires both of Turkey and of Persia. They are met with in the Persian provinces of Khorassan and Armenia, as well as Ardelan and the pachalick of Bagdad, and dispersed also in the Diarbekr, and over the plains of Arzroum, Erivan, Sivas, Aleppo, and Damascus. They have been gradually extending themselves over the Lower Asia, and in other directions, particularly within these last hundred years; great numbers, as is alleged, of tribes and families having been detached from the nation, in consequence of the disputes inseparable from the anarchical state of their feudal government, in which each village, it is said, had its chief, and the whole country was parcelled out among a number of different and independent factions. There are, however, two principal and well recognised portions of territory which enter into the description of Curdistan, namely, the Lower Curdistan, or that portion of the pachalick of Bagdad which is situated beyond the Tigris, and which corresponds nearly to the whole of ancient Assyria Proper; and the province of Ardelan, which forms the eastern division of it. The first of these extends from Armenia, and the territories of the chief of Julamerick, to

Limits.

the district of Mendeli, which is its frontier towards Kuzistan. It is surrounded on the north and east by lofty mountains, and is divided into the districts of Solymania, Kerkook, Erbille, Amadia, Shahre-van, Zohaub, Bedri, and Mendeli; each of which has its separate hakem or governor. The province of Ardelan is in length 200 miles, extending from the little river Sharook to the Turkish district of Zohaub; and nearly 160 miles in breadth. It is divided from the plain of Hamadan by a small range of hills; and its western boundary is 100 miles beyond Senna, the capital, which has been ascertained by actual observation to be situated in latitude 35° 12′ north, and longitude 40° east.

General aspect.

The face of the country is different in different parts. That portion of it which lies to the north of the Little Zab being every where well watered and happy, in a fertile soil, has been in all ages particularly productive. It still continues to supply Bagdad, Mosul, and other cities in that quarter, with corn, cattle, cheese, butter, dried fruits, and almost every other kind of provision. The same character, as to fruitfulness, which belongs to this division, is, though perhaps in an inferior degree, pretty generally applicable to the whole of the province of the Lower Curdistan. That part of it to the north of Tooz Khoorma, a small town situated on the road to Mosul, at the distance of about forty-five leagues from Bagdad, has a flourishing and picturesque appearance, being covered with towns, villages, and gardens of fruit trees, and is in a highly improved state of cultivation. In the division of it lying to the south-east of Tooz Khoorma, the soil is more of a sandy nature, and the heat is more intense; consequently in this part the produce is less considerable, and the population proportionably scanty. Here, as well as in the Jezira, the cultivation is confined to the environs of the villages, which are thinly scattered over the surface of a naked plain. In the district extending from Sarakpoola to Solymania, nothing is to be seen but rugged and stupendous mountains, crowned with forests of stunted oak. In the province of Ardelan, the face of the country from the little river Sharook, by which it is separated from Arzerbijan, to Senna, is pretty uniform; and, indeed, it continues to retain the same character as far as to Kella Shah Khanee. It presents to the view either progressive clusters of hills, heaped as it were upon each other, or great table lands, covered with flocks and the tents of the Illiats, who pass the months of June, July, and August in this quarter, and in the winter remove to the neighbourhood of Bagdad. The intervening vallies, or rather glens, are narrow stripes at the foot of the mountains, where the villages are commonly built in situations proper for the protection of the inhabitants from the inclemency of the weather. These, however, are but few in number, as the Curds for the most part prefer a pastoral, and consequently a wandering life. For the same reason they content themselves with raising so much grain as is absolutely necessary for their subsistence. The soil, notwithstanding, is good, and might be made to yield abundance of wheat and barley. The oil plant is every where common here. Tobacco is cultivated in small quantities; and the mountains to the west of Senna are covered with forests of the finest oaks.

Rivers.

The principal rivers of the province of the Lower Curdistan, are the Diala, Great Zab, Little Zab, and Odorneh. The different branches of the Tigris also issuing from the mountains of this country, and surrounding the upper part of the Great Zab, pass on thence to the southward as far as the frontiers of the Irak-Adjemi, or Persian Irak. The Diala, rising in the mountains behind Solymania, whence it takes a southerly course, receives in its progress the tribute of a vast number of smaller streams. At about six or seven miles to the north of Kuzil Roobat, it unites with a river almost equal to itself in size, of which the source is at the foot of the pass of Kurren. Having now become a fine river, it still continues to proceed southward till it enters the Tigris, about five miles above Tauke Kesra. During the summer, the Diala is fordable at Bakooba, nine leagues from Bagdad, on the road to Kermanshaw. Just before it approaches the Tigris, it is near 150 yards wide; at which place a bridge of boats is thrown across it for the convenience of travellers. In the same range of hills with those of the Diala, and contiguous to them, are the sources of the Great Zab, the Zabatus of Xenophon, and Lycus of Ptolemy. This river at first pursues a northerly course, but after meeting with a small stream which comes from the district of Alhak, it proceeds in a westerly direction, unites with the Hakiar, or river of Julamerick, and then flowing towards the south-west, forms a junction with the Hazir Su, the ancient Bumadus, and disembogues into the Tigris at Toprukala, fourteen furlongs below Mozul. Between this place and Erbille the Great Zab can be forded only in the summer, and even then not without difficulty. The Little Zab is formed by the junction of a great number of little brooks, which originate in the hilly country to the east of Khoi Sindjack. It joins the Altun Su, or Golden Water, at Altun Kupri, which is sixty-eight furlongs distant from Bagdad, on the way to Mosul; and it terminates in the Tigris, at the village of Senn, thirty miles below Haditha. This is a narrow, but deep and rapid river. It is the same that was known to the Macedonians under the names Zabus Minor and Caprus. The Odorneh is, in like manner, formed from the union of several smaller streams, which have their rise in the hills between Kerkook and Solymania. It proceeds in a south-west direction, and falls into the Tigris twenty furlongs above Bagdad. At the village of Tooz Khoorma, above mentioned, the bed of the river is about sixty yards in breadth, and in spring it contains a great body of water.

Towns.

In Curdistan there are several considerable towns and hamlets. The largest of the towns of Lower Curdistan is Kerkook, which is situated in 35° 29′ north latitude. It lies in the direct road from Bagdad to Mosul, being at the distance from the former of 59 fursungs, and 41 from the latter. It stands on a commanding eminence, nearly perpendicular on all sides, below which is an extensive suburb. This city is defended by a mud wall, has 2 gates, 7 mosques, 14 coffee-houses, 1 hummum, 1 caravansera, 1 Armenian church, and 12 pieces of useless artillery mounted on the bastions. In the suburbs are 5 mosques, 9 small caravanseras, 13 coffee-houses, 3 convents, and 3 Catholic churches. The streets of the town are narrow and filthy, and the houses very mean. The population has been estimated at 18,000 souls, Turks, Armenians, Nestorians, and Curds; but this estimate is probably considerably beyond the truth. The country around the town is uneven and hilly; and on the north side, a low range of barren and rocky mountains separate the district of Kerkook from the fine plain of Altun Kupri. Kerkook appears to have been formerly a Roman station, and from the nature of the ground on which it stands, it still retains, when viewed from a distance, the appearance of a Roman fortress. It is the same town which is entitled

Curdistan. Towns.

Demetrias, by Strabo and by Ptolemy Corcura. Eighteen leagues to the eastward of this city is the town of Solymania a Shehr e Zour, which, in the retreat of Heraclius, is distinguished by the name Siazuros. Shehr e Zour having fallen into decay, was some years since rebuilt by Solyman the Great, pacha of Bagdad, and thus it received from him its present name. It is situated in a delightful country, close to the foot of Mount Zagros, and contains about 6000 inhabitants. It is the residence of Solyman, pacha of Curdistan, a distinguished warrior, who in 1810, at the instigation of the Porte, took arms against his master the pacha of Bagdad, whom he defeated, and put to death. The haken, or governor, who resides here, and who usually assumes this title just mentioned, must be by birth a Curd. He has the chief and most extensive of all the commands in the province. Not far from Solymania was the city of Holwan, the retreat of Yezdejird, after the battle of Cadesia, and to which the caliphs of Bagdad were accustomed to retreat during the heat of summer. It was ruined by Holaku, and has never since recovered its consequence. About 12 fursungs to the north-east of Altun Kupri, is the town of Khoi Sindjack, which, for many years, was the residenee of a pacha. Erbille though at present a wretched mud town, with a population not exceeding 3000 souls, appears to have been the Arbela so famous in history, for the final victory obtained by Alexander over Darius, and the capital of the province of Adiabene. Part of this town is built on a hill of a conical form, on which probably stood the old castle, and the remainder of it encircles the base of the hill. The country around it, and all along to Mosul, is fruitful, but hilly, and very deficient in wood, there being hardly to be seen here a tree, or even so much as a shrub. On the summit of a steep mountain, 18 fursungs north of Mosul, are the fort and town of Amadia, to which the only ascent is by a narrow flight of steps hewn out of the side of the rock. This city, as well as the province of the same name in which it is situated, are nominally subject to the pacha of Bagdad. But the Turks obtain no tribute from this province, which is in fact independent, and has continued subject only to its own native chieftains from the days of the Abassides. Exclusive of the dependent villages with which the place at the foot of the hill is every where studded, the town of Amadia does not contain above 600 houses. Shahr e Van, the ancient Apollonia, is peopled by about 4000 Curds and Turks, and is upon the whole a handsome little town, watered by two canals drawn from the Diala. Zohaub is in the same quarter, being like it situated on the high road from Bagdad to Hamadar. Mendali is about the same size as Solymania. It is surrounded by a number of fine gardens. The same is the case as to Bedri, which is the frontier town in this quarter of the Turkish empire. It is not quite so large as Mendeli, and the districts around it are damp and marshy, being interspersed with pools of water, the receptacles of the torrents, which in the spring continually rush from the adjacent mountains. Within the territories of Ardelan, secluded in a deep valley, which is well cultivated, and interspersed with orchards of peach, apricot, pear, apple, and cherry trees, Senna is at once a highly romantic and very flourishing little town. Besides about 2000 Jews, Armenians, and Nestorians, who reside here, and who trade to Mosul, Bagdad, and Ispahan, the population of the place may amount to about 6000 souls. The Wallee, who seldom quits it, resides in a sumptuous palace, built on the top of a small hill in the centre of the town, where he maintains a high degree of state and splendour, joined with the most liberal spirit of hospitality. In addition to these towns, Curdistan, in its largest sense, is understood likewise to comprehend Betlis, Scheresal, Harpel, Nineveh, Rehobo, Rhesen, and Van. Tribes also, or families of the Curdish race, form a considerable part of the population of Diarbekr, Mosul, Merdin, Palo, of Sok or Zog, which is governed by a powerful, independent, and hereditary prince, in the pachalick of Erzeroom in Armenia; and of the towns in Khorassan, subject to the similarly independent chief Meer Goonah Khan.

Curdistan.

State of agriculture.

The state of agriculture in Curdistan, differs in some respects from that which is most prevalent in the Persian dominions, water being in general so abundant as to prevent the necessity of irrigation. The grains most commonly raised in these parts are wheat and barley. Of the former there are two kinds, which are sown at three different seasons of the year. The first sowing takes place in March, and the crop is reaped in September; the second grain is sown in September, and reaped in July of the following year; and the last season of sowing is in October, of which the crop is reaped in the following August. When the second crop has attained the height of 7 or 8 inches, it is usual to turn in cattle to graze upon it for a certain period, after which it is permitted to acquire its proper maturity. This country is said to have been anciently reckoned more fertile than it is at present. It has been so much the seat of war, in former ages between the Parthians and Romans, and at a later period between the Turks and Persians, that it has been comparatively depopulated, and rendered waste and unproductive. It abounds with deserts, and except in the parts lying near to the towns, which are somewhat better cultivated, may be characterised as rather desolate and barren.

The Curds are brave and hospitable, but far more uncivilized than any of their neighbours. They are averse to settled habits. War and rapine are their delight, and murder and parricide they hardly consider in the light of crimes. They are robust, hardy, and temperate, and live to so great an age, that it is not uncommon to see men 100 years old in full possession both of their corporeal and mental faculties. But though stout and active, neither men nor women are at all agreeable in their persons, having very small eyes, wide mouths, bad complexions, very black hair, and a very fierce and forbidding aspect.

Tribes.

The tribes of Curdistan may be divided into two classes, consisting of such as live in tents, and of those who have more fixed habitations. The former, on the approach of winter, quit the more lofty regions, and retire gradually towards the warmer climate of the south. Here they remain during the cold weather, and return to their own country about April or May. They are often shifting their positions, in search of pasture for their numerous flocks and herds, and while the men are occupied with the care of these without doors, or roaming about in quest of plunder, the women employ themselves in making butter and cheese, and in training up the children to the mode of life in which they are to be afterwards engaged. The tents with which they accommodate themselves during their migrations are large and constructed, for temporary use, of cane hurdles, disposed in a square form, and covered with a sort of coarse brown cloth. The floors are matted, so as to answer at once the purposes of bed and board. When they are about to change their place, the huts are taken to pieces, and the oxen and cows loaded with them, and likewise

2

Curdistan. with the children and household utensils. The men are generally well mounted, and take great care of their horses, of which there is here an admirable breed, much esteemed for their size, beauty, and activity. In the management of these, as in that of their arms, the Curds are understood to excel: their principal weapon is the lance. The women ride either on horses or on oxen. The children can suffer little in this migratory sort of life, being brought up very hardy, and accustomed to go almost naked even in the coldest weather. In some of the parts which have already received our more particular notice, there is to be observed somewhat of a more stationary manner of living. That division of the territories of Ardelan, which extends in the direction of Kella Shah Khanee, is peopled by a tribe named Gheshkee, who are honoured by the Curds as the most expert and daring robbers of their nation. That torture may not induce them to betray their accomplices, the people of this tribe are habituated to pain from their earliest infancy, being beaten so unmercifully when children, that their bodies, in course of time, become almost insensible to outward feeling. The rugged district of the Lower Curdistan, situated between Sarakpoola and Solymania, is also noted as the habitation of one of the most savage of the Curdish tribes.

Government. The Curds possessing a wild and inaccessible country, have never been completely subdued by any of the great neighbouring states, but continue to live under the rule of a number of independent princes, who govern their subjects as absolutely as either the King of Persia or the Grand Seignior. According to the account given of them by Niebuhr, who travelled in these countries in 1769, they are subject in their mountains to a sort of feudal government, similar to that whcih is observed among the Druses. They are for the most part tributaries, at least in appearance, to the Porte, but they pay little respect to the orders of the Sultan or of his deputies. The wandering tribes in the vicinity of Bayazid, Van, Khoonoos, Moosh, Betlis, &c. pay no tribute at all to the Turkish government; but in cases of emergency they furnish the pachas with certain bodies of horse, equipped and maintained at their own expence. The most powerful of the Curdish chiefs are the Wallees of Ardelan and Solymania, of whom the former, though he condescends for the preservation of peace, to pay an annual tribute to the king of Persia, is in all other respects completely independent. He has the power of life and death over his vassals, whom, however, he governs more as a patriarch than as a tyrant. He is said to be the lineal descendant and representative of the great Salahadeen, and holds his court at Senna, his capital, 60 miles from Hamadan, and 77 from Kermanshaw. The governor of Solymania holds in a similar manner of the pacha of Bagdad. At the period of the late troubles, so much was the usual order of authority set aside here, that a creature of the Curdish chief was advanced to the chair of his superior, which had been previously vacated in consequence, in a great measure, of his vigorous and spirited proceedings.

The Curds in their different tribes are proud of their descent, and fond of tracing the families of their chiefs to the most fabulous ages. In this respect they differ from their neighbours the Turkmans, also a wandering and pastoral people, who pay no respect to nobility or antiquity of extraction. Instead too, like them, of giving a portion with their daughters whom they bestow in marriage, they receive a premium for them. But what is to those in their vicinity the most offensive line of distinction between them and a people with whom in the main they agree as to their modes of life, is, that the Curds are every where considered to be addicted to theft and robbery. On this account they are much dreaded in the neighbourhood of Aleppo and Antioch, where, under the name of "Bagdashlia", they occupy the mountains to the East of Beelam, as far as near Kles, their number in this pachalic and in that of Damascus exceeding 20,000 tents and huts. Their tribes taken altogether are estimated to contain more than 140,000 men capable of bearing arms. Curdistan.

The Curds dress in a manner different from either the Persians or Turks. They speak also a language of their own. In this language there are three distinct dialects. It is said neither to have the aspirations or the gutturals of the Arabic, nor to resemble the Persian: in which case it is most probably an original language. Volney conjectures, that a knowledge of this tongue, considering the antiquity of the people by whom it is spoken, and that they are related to the Medes, Assyrians, Persians, and even the Parthians, might throw some light on the ancient history of these countries.

The state of the Curds, as to mental cultivation, is very deficient. They are seldom taught to read or write. In respect to religion, the majority of them are reputed to be Mahomedans of the Soone sect; but they trouble themselves little about religious opinions or rites. Several of them, distinguished by the name of Yardia, worship Shartan, or Satan, according to the ancient system of the good and evil principles, which has been so prevalent in the Diarbekr, and about the frontiers of Persia. There are among them also Armenians, Jacobites, and Nestorian Christians. Indeed every where throughout Curdistan, there are many towns and villages entirely inhabited by persons of the latter persuasion, who have their priests and bishops, and are in general an industrious people. The Gheshkee, though thieves and robbers by profession, are slaves to the most abject superstition. Of this the following is an example. There have been collected at Kella Shah Khanee the ruins of the castle of Shah Khan, a distinguished Ameer in the court of Chosroes Purviz, a few loose stones for the purpose of marking the abode of a *peer ghaib*, or invisible saint. On one of these stones it is usual, when any person belonging to the neighbouring tribes is unwell, to place a piece of bread steeped in oil or butter, with the view of propitiating the saint, and inducing him to recover the patient, which it is conceived in these circumstances he seldom fails to do. Education and religion.

There are among the Curds few of the means for the prosecution of any considerable commerce. The fine timber produced in the oak forests of Ardelan being made into rafts, is floated down the Zab into the Tigris. The gall-nuts, of which they likewise yield abundance, are, as an article of trade, exported to India. To the north of Kerkook, likewise, in the vicinity of Mendeli, there are naphtha pits, which yield an inexhaustible supply of that useful commodity. It is thence distributed over all the neighbouring country. This substance is an excellent substitute for pitch. The bottoms of most of the vessels which navigate the Euphrates and the Tigris are covered with it, and it is also used by the natives in their lamps instead of oil.

The circumstances and national character of the Curds appear to have undergone little change even from the remotest times. They are supposed to be the same people who are mentioned by Xenophon under the denomination of the Carduchai, and whom he states to

Curiatii || Curling.

have opposed the retreat of the ten thousand. This historian observes, that though shut in on all sides by the Persian empire, they had constantly braved the power of the great king, and the arms of his Satraps. The same, it will be perceived, continues to be still a pretty accurate account of their present condition. Their rude and barbarous customs have also remained without variation. The only considerable change, if that be not also more nominal than real, is in the article of religion. Volney takes notice of the similarity in sound between the names Curd and Gord, and thence suggests, that the original seats of the Curds may have been the Gordæan mountains, or the Gordonæi, where, according to the Chaldean Berosus, and the Armenian Maribas, cited by Moses Chorenensis, Xisuthrus landed, after escaping from the deluge. The Curds themselves still boast of being the direct descendants of Noah. See Niebuhr's *Travels*; Volney's *Travels*, vol. i.; and Kinneir's *Geographical Memoir of the Persian Empire*, passim. (K)

CURIATII. See Rome.

CURL. See *Potatoes* in Agriculture Index.

CURLING, the game of, is a winter amusement almost peculiar to Scotland. It is played by sliding stones along the ice to a particular mark, and has some resemblance to the games of *bowls* and *billiards*.

Stones employed.

The stones employed in it are of a spherical form, flattened above and below, so that their breadth may be nearly equal to twice their thickness. The upper and under surfaces are made parallel to one another, and the angles of both are rounded off. The under surface, or *sole* as it is called, is polished as nicely as possible, that the stone may move easily along. The blocks from which they are made are of whinstone, or granite, of a close texture, free from cracks, and capable of taking a fine polish. Those whinstone nodules, called *yolks*, on account of their toughness, and never breaking into large fragments, are reckoned the best. They have bent iron or wooden handles, and are from 30 to 60 lbs. avoirdupois weight, according to the strength of the person who uses them.

Rink.

The place where the stones move is called the *rink*, the chief property of which is that the ice be level, smooth, and free from cracks, particularly such as are in a longitudinal or oblique direction. A mark or hole is then made at each end called a *tee, toesee*, or *witter*. Round this two circles of different diameters are drawn, that the relative distances of the stones from it may be calculated at sight; as actual measurement is not permitted till the playing at each end be finished. These circles, in the technical language of the game, are called the *broughs*. A score drawn across the rink at each end, distant from the tee about a sixth part of the length of the rink, is called the *hogscore*. The length of the rink from tee to tee varies from thirty to fifty yards. The breadth is about 10 or 12 feet. When the ice is covered with snow, it must be cleared to that extent, and also ten or twelve feet beyond the tee, at each end, that the stones, when impelled with too much force, may have room to get far enough not to be of any use.

Number of players.

The number of players upon a rink is eight or sixteen; eight when the players use two stones each, and sixteen when they use one stone each. There may be one or more rinks according to the number of curlers. The game may also be conducted by one person against another, by two against two, or three against three, each using one or more stones, as it may be agreed upon.

He who is reckoned the best curler has generally the power of arranging the order of the players, and whoever is last in order, gives directions to all the rest of his party. He is called the *driver*, and the first the *lead*.

The method of conducting the game.

The game at first is remarkably simple. The lead endeavours to lay his stone as near the tee as possible. If it be a little short of it, upon the middle of the rink, it is reckoned to be fully better laid than if it touched it. The object of the next in order is nearly the same as that of the lead. The next attempts to guard the stone of his partner, if it be near the tee, or to strike off that of his antagonist if it be nearer. The one who follows, if a stone belonging to his own party lie nearest the tee, tries to guard it; if one of the opposite party, to strike it off; or if no stone be near the tee, *to draw a shot*, that is, to make his stone rest as near the tee as he can.

As the game advances, it becomes always the more intricate. Sometimes the stone nearest the tee, which is called the *winner*, is so guarded, that there is no possibility of getting at it directly. It then becomes necessary, in order to get it removed, to strike another lying at the side in an oblique direction. This is called wicking, and is one of the nicest parts of the game. But when the winner cannot be reached even in this way, the last in order but one or two must endeavour to remove the opposing stones, by striking them with great force. Sometimes the stones are so situated, that the driver, to avoid the risk of losing any shots which his party may have gained, throws away his stone without attempting any thing. When the stones on both sides have been all played, the one nearest the tee counts one; and if the second, third, fourth, &c. belong to the same side, all these count so many shots, thirty-one of which for each side is the number usually played for.

Its origin.

The origin of this game is yet involved in obscurity. While most of our national amusements are to be found recorded in the writings of the antiquary and historian, we find no mention made of this before the beginning of the seventeenth century. About that time, the allusions to it are such as clearly prove that it was then pretty generally practised. It is probable, however, that its origin does not go much farther back; because, if it had existed much earlier, it could hardly have been omitted in those lists which have been transmitted to us of the ancient amusements of our country. But in none of those lists do we find it ever mentioned, nor does any author make the least allusion to it previous to that period. In the statutes of the fifteenth century, we find a list of amusements, amongst which are golf and football, particularly prohibited by authority, in order to promote the noble art of archery, as it is called. But nowhere do we find a single hint about the game of curling. It can be practised, it is true, only for a short time in the winter; but when it is practised, it must, from its very nature, be public, and known to the whole neighbourhood. On which account, had it then existed, it could hardly have been overlooked by those who have particularly enumerated the Scotish amusements of the fifteenth and sixteenth centuries.

In later times, when it is known to have flourished in this country, we find it forming a favourite subject for poetic description. Not satisfied with allusions, the votaries of the muses have allotted to it whole poems, and expatiated with the feelings of a curler, upon the various circumstances connected with this *manly Scotish exercise*. Now, since we do not find it even mentioned

Curling.

before that time, it is highly probable that it did not then exist, or that it was only in its infancy.

The country where it originated.

Connected with this, is the inquiry respecting the country in which it originated. Upon this subject there are different opinions. Some seem to think that it was an amusement originally Scotish; others, that it was introduced into this country from the continent. The latter of these opinions appears to be best founded.

We have not been able, indeed, to find any direct evidence that it existed on the continent before it appeared in this country, but we have all the evidence which etymology can give in favour of its continental origin. The technical terms employed in it are all Dutch or German, and therefore point to the Low Countries as the place in which it most probably originated, or at least from whence it was conveyed to us. For if it was not introduced from the continent, but was first invented in this country, it must have been at a time when the German and Low Dutch were the prevailing languages. Now though the Saxon was once pretty common in this country, and there are still many Dutch words in our language, yet those German dialects were never so general, as to make it credible that our countrymen, in any particular invention, would employ them alone as the appropriate terms. In the history of inventions, such a phenomenon is not to be found. The origin of the game, then, is certainly continental.

But we have farther evidence that curling, or something like it, was originally practised on the continent. Kilian, in his Dictionary, renders the Teutonic *kluyten, kalluyten, ludere massis sive globis glaciatis, certare discis in equore glaciata.* Whatever those round masses of ice were, they seem to have been employed in a game on the ice resembling quoits. Indeed it is highly probable that the game which we now call curling, was originally nothing else than the game of quoits practised upon the ice. Besides, the game of curling was, till lately, hardly known by that name among the common people. From one end of Scotland to the other, it was always named *kuting,* to curl meaning nothing more than to slide upon the ice. The games are so similar, that the one might easily arise out of the other, and assume that form in which it at present exists.

Hence we conjecture that the game of curling was introduced into this country by the Flemings, in the fifteenth, or about the beginning of the sixteenth century. In the reigns of Henry V. and VI. of England, and James I. of Scotland, many of them came over to this country, which had been much depopulated during the destructive wars betwixt the two kingdoms, and settled in it as mechanics and manufacturers.

Its progress.

Curling is said to have been carried into Ireland by the Scotish colonies which were planted there so early as the reign of James I. of England. In that country, however, it seems now to be completely unknown. It has made its appearance in some of the northern counties of England, and has even found its way to the capital of the British empire. There the first essay was made upon the New River; but the crowd of spectators attracted by such a novel spectacle becoming very great, the ice threatened to give way, and the curlers were compelled to desist. It has not been confined within the boundaries of Europe; it has been carried over the Atlantic, and established in the frozen regions of North America, and particularly in the province of Canada. There, on account of the length and severity of the winter, it bids fair to attain a degree of celebrity unexampled in the milder climate of Scotland. In this country, it can be practised only a few days in the season, so few, that for the last twenty years the average number is not more than eight; while in that country, the amusement may be enjoyed during the greater part of the winter.

Currency.

Its character.

There are few amusements which excite more interest than the game of curling. In the severest weather, a good curler, while engaged in his favourite amusement, feels no cold. In playing himself, and assisting his partners with his broom, he finds sufficient exercise to keep him warm. And being performed at a time when the labours of the field are at a stand, and when several mechanical employments cannot be carried on, it gives little interruption to business. It brings men together in social intercourse; it enlarges and strengthens the ties of friendship, and enlivens the dreary hours of winter with festivity and happiness. It may therefore be regarded as one of the most healthy and innocent amusements that are practised in this country. (*u*)

CURRENCY, in commercial and money transactions, is a word of as general import as "circulating medium." It may be said, indeed, that all the extension given by political economists to the word "money," is applicable to its synonyme "currency," and that the cowries of India, philosophically speaking, come as much under the description of "currency" as our bank notes or our guineas. We shall confine ourselves, however, to the ordinary acceptations of the word, viz. metallic or paper money, and shall restrict the present notice to a portion only of the observations belonging to the subject of MONEY, reserving the remainder for the discussion which we intend to give under the latter title.

Metallic currency.

Metallic currency. The keenest advocates for the abolition of restraints on trade and manufacture, will not refuse to admit the necessity of a stamp being put on the coin by government, or by some association of undoubted responsibility. Without such a precaution, there would be no security for the weight or the fineness of the coin. Here, however, the interference of public authority should terminate. To affix to a specific coin any other denomination than a mere declaration of its weight, is an act of supererogation; attended too, as such acts generally are, with considerable inconvenience. To declare an ounce of silver worth five shillings, is, in fact, to say nothing more than that it is worth an ounce of silver. It is merely giving a new name to the same thing, the five shillings being useful for nothing more than the ounce of silver. With equal propriety, might government enact, that wheat, coffee, or chocolate should assume a new denomination as soon as they are divided respectively into bushels and pounds. We are led to dwell on this peculiarity, not by a wish to multiply theoretical distinctions, but by the perplexing irregularity attendant, particularly of late years, on the state of our money system. After all the discussions that have taken place on the bullion question, the majority of our countrymen are still at a loss to account for the remarkable difference between the market price and the coinage value of silver. Had our coins been known merely by their weight, had our crowns, for example, been nothing but ounces of silver, one material cause of perplexity would have been removed. Relatively to gold, silver might have fluctuated, as it is always liable to do, but no difference could have existed between silver in coin and in bullion, except that which might arise from their comparative fineness. In that case, it would have been clear, that the existing depreciation applies to our bank notes, and that it arises less from an over-issue of them, than from their being inapplicable to the purposes of foreign expenditure. In all cases of embarrassment, it is a main point to ascertain the source of the evil; an explanation of which paves the way for the adoption of the measures, frequently unpopular, which are requisite to effect a remedy.

The approximation, on this plan, to uniformity in price, would not be impeded by the plan of adding alloy to the coin. Gold or silver in bullion are not necessarily pure; on the contrary, these metals are, in every situation, more durable in consequence of the admixture of alloy.

Paper currency.

Paper currency seems the last refinement which it is possible to make in saving the expence of a circulating medium. It is, in fact, the exchanging the use of a commodity of great value for one of almost no value whatever. In the case of so decided a transformation, nothing, it is clear, can support credit except a thorough confidence that the article of value will be forthcoming on the presentation of its representative. It is, however, remarkable, that popular ardour, in certain circumstances, has given currency much longer than might have been expected to paper issues of a doubtful description. The grand period for obtaining circulation in this way, is the era of some remarkable revolution. The minds of men are then too much agitated by favourite anticipations, to dwell with coolness on the fate which must overtake the unchecked issue of paper. The war of 1775, on the part of the United States of America, and still more the French revolutionary war, are memorable instances of the length to which such fallacious emissions may be carried. Though used in the most lavish manner, their credit, in either case, lasted long enough to enable the respective governments to baffle all the efforts of their opponents.

In reverting to the memorable bubble of the Mississippi, it is due to the character of Law to mention, that he was not responsible for the monstrous abuse which was made of his views and projects. His ideas, as developed in his publication entitled *Considerations on Money and Trade*, imply a very different course from that which the French government thought proper to take. The bank founded by him in France in 1716, issued notes expressed in the following terms:

"The Bank promises to pay the Bearer at sight ——— livres, in money of the same weight and denomination as the *current money of the present date.*"

Such continued the form of the bank notes until 1719, and so far all went on well. But in that year the government of the Duke of Orleans thought proper to buy up the bank shares, and to give to this establishment the character of a government concern. It now received the name of *Banque Royale*, and the notes were expressed as follows:

"The Royal Bank promises to pay the Bearer at sight, ——— livres *in silver.*"

This change, slight as it apparently was, became a very serious matter in a country where government assumed the power of debasing the coin. It made the bank responsible, not for the coin current at the time of issue, but for its reduced value at a subsequent date. It was in vain that Law raised his voice against this innovation. Power got the better of argument, and, by a singular perversity, the faults resulting from an arbitrary exercise of authority were laid to the charge of erroneous principles. We have already expressed, under the head BULLION, our conviction, that the present depreciation of our bank paper exists chiefly in regard to foreign transactions. At home, the degree of depreciation appears to us comparatively small, and confined in its course to the operation of the enhancement of foreign articles. The wonder is, that, involved as we have been in a contest requiring such an amount of foreign expenditure, and with a bank restrained by no direct enactments in regard to its issues, the amount of our bank notes, and the consequent fall in their value, should not have been greater. The result is sufficient to shew, both the moderate views of the managers of the bank concerns, and the latent checks which exist in regard to a power of circulation apparently unbounded. The Bank of Ireland increased its issues with much more rapidity, after the exemption from cash payments, than her sister establishment. In France, on the other hand, the distrust attached to paper money since the ruinous days of the assignats, has put it out of the power of government, or of the Bank of Paris, to exceed a circulation of three or four millions sterling. Had it been otherwise, there can be no doubt that the French government, so far from imitating the prudence of ours, would have gone still farther in the course of over-issue and depreciation than the comparatively moderate cabinets of Austria and Sweden.

In the late discussions on the bullion question, the mercantile interest were almost unanimous in favour of the bank and of ministers. This arose, in a great measure, from an apprehension that the obligation to resume cash payments would necessitate a great reduction of the circulating medium, and would bring down on trading people all the evils attendant on scarcity of money. In the actual circumstances of the country, there can be no doubt that a sudden diminution of our circulating medium would have formed a severe aggravation of our previous embarrassments. But, speaking in a general way, there can be nothing less necessary or less politic, than to provide, by enactments of government; for the introduction of a circulating medium currency, we may take for granted, will never fail to provide for itself. The necessity of interchanging commodities calls for a circulating medium, and the money at hand will be made, one way or other, to answer the purpose. The chief difference arising from its scarcity or abundance, will consist in its higher or lower value.

With the view of ascertaining the limit to which a government should permit the currency of bank notes, Dr Smith enters at some length into the principles of the circulation of money. He divides it into two distinct branches;—the circulation in the wholesale trade between dealer and dealer, and the retail circulation between dealer and consumer. The latter being carried on in small sums, ought, he thinks, to be confined to metallic currency; while the former may, without hazard to the public security, be managed by bank notes. It would be highly impolitic for a country to divest itself wholly of the precious metals. For an advantage of no great consequence, it would thus become stripped of that circulating medium, which forms the currency of all the rest of the civilized world. Remove the check of cash payments, and there is no saying to what length the overissue of paper may be carried. Recent experience has shewn, that without any intention of imposing paper currency on the people, we have brought ourselves into a situation in which our notes bear a reduced value in comparison with coin. The exchange is consequently adverse to us in all directions; an evil which, whether we view it as obstructing our supplies of corn, or as crippling the foreign exertions of our government, is productive of incalculable mischief.

The limits suggested for our paper currency by Dr Smith were L. 10 as the lowest bank note in London, and L. 5 as the lowest in the country. These recommendations were adopted by government about forty years ago, and were productive of much advantage. The mass of small notes, circulating frequently for five shillings or less, was made to disappear, and the restriction was not attended with any material injury to trade. Banks of circulation continued to make loans as before to farmers, merchants, and manufacturers. The first deviation from Dr Smith's plan took place above twenty years ago, but was comparatively trifling, for it consisted in nothing more than a permission to the Bank of England to issue, like the country bankers, notes of L. 5. The grand alteration took place in 1797, on the suspension of cash payments; a step which was necessarily accompanied by an unlimited permission to issue notes of L. 1 and L. 2. From that time forward, paper has been regularly taking the place of gold and silver in our currency. Every year has added more or less to the substitution; but the foreign subsidies, and the corn importations of 1799, and the years immediately subsequent, carried off our specie by wholesale. Our bank paper then fell between 2 and 3 per cent. below our coin, a fall which it has never recovered. The final blow was given by our Orders in Council, and by the heavy drain of specie attendant on the prosecution of the war in Spain. Had government adhered to the precautions of Dr Smith, and kept our foreign expenditure within bounds, the crisis of 1797 would not have occurred. And had they, at the subsequent date of 1807, forborne to interfere with the course of trade, the evil would have been comparatively limited in its operation. A great part of the supplies necessary for the Spanish contest would have been furnished by the Americans, who would have taken (as they are always ready to take) payment in British manufactures. Moreover, the sums of money which we might still have found it necessary to expend in the peninsula, would have found their way back to us, directly or indirectly, through the endless channels of an unrestrained commerce. With this view it is important to remember, that the American trade with the continent regularly supplied us with four millions annually, in the shape of bill or specie remittances. This was a fund lasting stedfastly all the year through, and generally affording us between L. 150,000 and L. 200,000 a week. Unfortunately the silent and imperceptible manner in which these remittances took place, prevented our government from comprehending their magnitude, until the "deed was done," and we had, with our own hands, blocked up this ample source of supply. (χ)

CURRIE, James, M. D. was born in the south of Scotland, in that district of Dumfries-shire which derives its name from the river Annan. His father and grandfather were both clergymen of the church of Scotland. He was an only son, but had six sisters, two of whom survive and are respectably married, one of them to an eminent surgeon in London, and the other to a cousin of her own, a merchant in Liverpool. At the time of his birth in 1756, his father held the living of Kirkpatrick Fleming, but was soon afterwards removed to the neighbouring parish of Middlebie, where he ended his days before his son had attained his 18th year. His wife, Jean Boyd, a descendant of the ancient family of Kilmarnock, and a woman remarkable for the strength and cultivation of her understanding, died whilst the subject of this sketch was still at a very early age; but this loss was amply compensated to the family by the benevolence of Miss Christian Duncan, a half sister of Mrs Currie, who undertook the superintendence of the household, and dedicated her life to the service of her young relatives.

Under the eye of these estimable guardians, he received the first rudiments of education at the parochial school of Middlebie, and from their example insensibly imbibed those endearing qualities, which formed through life so remarkable a feature in his character. At the age of thirteen, he was sent to the grammar school of Dumfries, which was then ably taught by Dr Chapman, whose work on education has gained him deserved fame. Into the house of this eminent teacher he was received as a boarder, where he remained some time after he had finished his course in the school, for the purpose of learning mathematics and practical geometry.

Soon after leaving school he accompanied his father in a visit to Glasgow, at which college the worthy clergyman had received his education, and where he still retained some intimate friends. The bustle and enterprise of this flourishing place, opened a new scene to the ardent imagination of young Currie; and having caught the spirit of adventure common to his countrymen, his father was persuaded to send him out to Virginia in the service of a company of merchants. He sailed for America in 1771, where he remained five years, and underwent many hardships, having suffered from a long and dangerous illness, and been treated with harshness and neglect by some individuals in that country with whom he was connected. To add to his misfortunes, during this period he lost his father, by which blow he was at once deprived of a counsellor and friend, and reduced to depend for subsistence on his own industry; the produce of the family estate, which was indeed but trifling, being generously resigned by him for the support of his sisters. These complicated calamities, however, did not relax the native energies of his mind; and young as he was, he took an active part in the political discussions which then agitated the American colonies, and ended in their separation from the mother country. Though convinced of the impolicy of a war with our dependencies in that quarter, and from his local knowledge anticipating an unfavourable result, he had, in common with the great majority of his countrymen in Virginia, formed a decided opinion in favour of the rights which the British administration assumed of taxing the colonies; and he published in an American newspaper, some letters expressive of his sentiments, under the signature of "an Old Man," which gained him amongst his party a high but dangerous reputation. As soon as the troubles began to assume a more serious aspect, and to interfere with the regular course of mercantile pursuits, he went to reside with Dr Currie at Richmond, a near relation of his, and the principal physician in the colony, who persuaded him to change his line of life, and to adopt the profession of medicine, to which he had been originally destined. It was concluded between this gentleman and himself, that he should go back to Britain, and prosecute his studies at the university of Edinburgh, and after taking his degree, should return to practice medicine in the capital of Virginia. Before all this could be accomplished, it was confidently expected that peace would be restored. In prosecution of this plan, he accordingly set out for Britain by the way of the West Indies, as direct communication with the

Currie. mother country was by this time interrupted. He took his route from North Carolina by St Eustatius and Antigua, and after making some narrow escapes, having at one time fallen overboard, and being at another driven by stress of weather into the Azores, where he was exposed to the imminent risk of shipwreck, he arrived at London in the year 1776.

From London he went to Edinburgh, where he constantly resided for three years, prosecuting his medical studies with zeal and success, and gaining for himself a high reputation among his fellow students. In the Royal Medical Society, of which he was a distinguished member, some papers of merit written by him are still preserved, one of which we shall afterwards have occasion to mention, as it is of some importance in the history of one of the most happy discoveries which have ever been made in the healing art.

During the prosecution of his studies at the university, Currie resided in the house of his aunt Miss Duncan, who, on the death of his father, had removed to Edinburgh with his sisters, and to whom he was now partly indebted for the means of support. The funds of this benevolent woman, however, were but scanty, and he was well aware that, with his utmost economy, his necessary expences must strain her resources. He knew, indeed, that she would chearfully have divided with him her last shilling; but, under no circumstances, would his spirit have suffered him to remain easy in a state of dependence; and, situated as he was, he felt inexpressible distress, from the consciousness of adding to the burdens of his best friend. He resolved, therefore, at all hazards, to find out some opening, where he might have an opportunity of subsisting by his own exertions. With this intention he turned his views to a medical appointment in the army, and procured an introduction to General Sir William Erskine, who gave him an ensigncy in his regiment, with the office of surgeon's mate. Some of his friends, however, hearing of the step he had taken, thought the situation inadequate to his abilities, and determined to use their influence, for procuring him a more honourable and lucrative employment. A medical establishment being at that time about to be formed for the forces in Jamaica, it was resolved that an attempt should be made to place him on the staff of the army, by getting him appointed physician, or assistant physician, to the hospital in that island. No time, however, was to be lost, and a difficulty of considerable magnitude occurred. Though he had attended the university during the regular term, he had not yet graduated, and there are only two days in the year in which medical degrees are conferred in Edinburgh, the nearest of which (the 24th June) was two months distant. This difficulty was overcome, by his procuring a degree from the college of Glasgow, and he immediately began to solicit for his appointment. Except among his fellow students in the university, he had few friends, for he had lived a retired life of hard study, and of necessary economy. Among these, however, there were many to whom his virtues and talents had warmly endeared him, and who were eager to use their interest in his favour; and indeed some of the professors were not insensible to his merits, and offered their services in the most flattering manner. He went up to London, therefore, loaded with letters of introduction, which represented his character in terms of merited approbation. He was, however, unsuccessful. On his arrival, he found the appointment filled up by a young Irish physician, a man of great merit, the interest of Sir John Pringle having yielded to that of Mr Surgeon General Adair. Before leaving Scotland, he had, at all events, determined not to return; and contemplating the probability of a disappointment, he had formed the resolution, even in this case, to proceed to Jamaica, and attempt practice there, in the certain hope of having an easy opportunity of passing to his friend and kinsman at Richmond, so soon as peace should be re-established. It happened that the fleet in which he was to sail was delayed from time to time, in consequence of which he passed the greater part of the summer of 1780 in London. He here renewed his intimacy with a few of his college acquaintances, who had become eminent for their literary and professional talents, and was introduced into some of those circles, which render London to a man of taste and genius so desirable a residence. In this society, his abilities were quickly appreciated, and his friends began to persuade him, that he might obtain success in his profession, without the necessity of leaving the kingdom. He listened to such agreeable suggestions at first without hope; but on hearing them repeated and warmly urged, he began to see in them something plausible as well as flattering, and willingly suffered his mind to indulge in prospects so congenial to his wishes. An illness with which, about this time, he was seized, added strength to the arguments of his friends, and when at length the fleet sailed, he allowed it to depart without him, determining to wait for the next convoy, and, in the mean time, to put these arguments to the test of experience, by endeavouring to find a settlement in England. In the course of his enquiries, he paid a visit to some of his acquaintances in different parts of the country, and after some unsuccessful attempts in other places, hearing of Dr Dobson's removal to Bath, he repaired to Liverpool, where that gentleman had left a flourishing practice, and he settled in this great commercial town on the 7th of October 1780. At the time of his arrival, he was not acquainted with a single individual, but he was warmly and affectionately supported by some of his early friends, and he carried with him about forty letters of introduction, which procured him many invitations, and, by making him generally known, prepared the way for more useful connections. By great and persevering exertions, he secured to himself part of the vacant practice; and his prospects were brightened in 1783, by his marriage with Miss Lucy Wallace, a lineal descendant of the Scottish hero of that surname, and daughter of an Irish gentleman, who was settled in Liverpool as a merchant, and whose probity, honour, and worth, had gained him universal respect. Currie.

Previous to this fortunate event, he had formed an intimate acquaintance with the then most remarkable in Liverpool for their taste and science; and in 1782, was the chief instrument in forming a literary club, of which Mr Roscoe, who has since by his writings acquired such deserved celebrity, and that most admirable man William Rathbone, were constituting members. Speaking of this circumstance in a MS. account of his life written by himself, and contained in a confidential letter to a friend, from which the principal facts mentioned in the former part of this memoir are taken, he expresses much amiable satisfaction. "I am proud of this," says he; "it was the means of binding us all in friendship and confidence, and gave a considerable impulse to my literary pursuits." This society acquires additional importance when it is remembered, that it was the first institution of the kind in Liverpool, and may justly be considered as the parent of those splendid literary establishments which now embellish that flourishing town, and in the formation of which Dr Currie took so active a part.*

About the time of Dr Currie's settlement in Liverpool, his ingenious friend, countryman, and early companion Dr Bell, commenced practice with the most flattering prospects in the town of Manchester, and a constant intercourse of affection was kept up between them. In January 1784, Dr Bell was seized with an illness which terminated in his death; and the anxiety of friendship induced Dr Currie to pay him the most assiduous and unremitting attention. This, however, could not be reconciled with the duties of a rising practice without much personal inconvenience, and he was frequently forced to travel to and from Manchester under night, at a time when he was by other exertions much harassed and fatigued. The weather being during that season extremely severe, his efforts proved too violent for his constitution; and immediately after his return from Dr Bell's funeral, he was attacked with an inflammatory fever, which threatened his life, and had nearly deprived the world of those discoveries and writings by which he has since immortalized his name. The disorder afterwards settling on his lungs, gave rise to a severe cough, which seemed to indicate the approach of consumption. Dr Darwin inserted in the 2d volume of his Zoonomia, an account of this illness, and of the plan of treatment which Dr Currie successfully pursued. Soon after his recovery, which did not take place till autumn, he wrote a memoir of the life of his amiable and accomplished friend and benefactor, in which he paid an elegant tribute to the memory of departed worth. This work, which was his first acknowledged appearance from the press, was undertaken at the request of the Manchester Philosophical and Literary Society, and being published in the first volume of their Transactions, gained him considerable credit as an author.

An illness at that critical period of a young physician's life, when he first begins to be known, is frequently very detrimental to his views; but notwithstanding this unfavourable circumstance, Dr Currie's practice rapidly advanced; and the respectability and public esteem into which he quickly rose, fully realized the hopes, and justified the discernment of his friends. The endowments of his mind, indeed, and the qualities of his heart, united to the accomplishments which books and an extensive knowledge of mankind had enabled him to acquire, were such as could not fail to inspire confidence in his professional skill, and a warm and affectionate attachment to his person. His figure, which was tall and commanding, gave a dignified effect to his first appearance among strangers, which the good sense and intelligence of his countenance contributed to heighten, and which a more intimate acquaintance with his character and manners served strongly to confirm. In that easy kind of philosophical conversation, which is so much the delight of men of letters, he was peculiarly formed to shine; and no person ever left his company without feeling his mind enlightened and his taste gratified. But there was something more than the elegance and variety of his language, and the discriminating sagacity of his remarks, which gave a charm to Dr Currie's society, and raised him to a distinguished station among his contemporaries. In his professional capacity, he displayed a degree of skill and knowledge which could only be acquired by assiduous habits of study, and a talent for minute and accurate observation, joined to that manly self-confidence and promptness of decision, which distinguished the man of action from the man of mere speculation. Thus gifted, it is not surprising that he commanded an extensive practice in spite of the disadvantages of his situation, and found his company courted by men of all ranks who had any claim to literary acquirements. He was elected a member of the London Medical Society in 1790, and communicated to it an essay on "*Tetanus and Convulsive Disorders*," published in the third volume of its Memoirs. In 1792 he became a Fellow of the Royal Society: this, however, having been conferred upon him as an acknowledgment for having presented to that learned body a very curious and instructive paper, containing "An Account of the remarkable effects of a Shipwreck on the Mariners, with Experiments and Observations on the influence of Immersion in fresh and salt water, hot and cold, on the powers of the living body." This communication was published in the *Philosophical Transactions* of the year in which it was received, and may be considered as the first fruit of an ingenious and useful investigation, to which the Doctor had turned all the powers of his vigorous and persevering mind, and which ended in one of the most important discoveries that the history of medicine has to record.

To every thing that concerns the welfare of his species, Dr Currie's mind was peculiarly alive, and the interest he took in the political events of his day, amounted frequently to an agitating solicitude. We have already recorded a proof of his patriotic ardour, which displayed itself in the efforts of his juvenile pen at the commencement of the American revolution. Another instance of the same spirit occurred during his residence in London, in the summer of 1780, when the metropolis was the scene of those disgraceful riots which have consigned the name of Wilkes to infamous renown. Indignant at the conduct of the magistrates, and of the opposition in Parliament, he employed his talents in defence of administration, by writing a series of letters in the Public Advertiser, under the signature of *Caius*. These letters, which are three in number, and were afterwards republished by some unknown hand, in a collection of political papers, evince a masculine mind, and a heart deeply interested in the cause of his country and of human nature. In these publications, it will be remarked, he adopted the views of the Tory party, to which, in the early period of his life, he had an attachment. His political principles, however, gradually and insensibly took another bias; and the same patriotic feelings which led him in times of turbulence and anarchy to lend the weight of his talents in support of the crown, made his mind, under other circumstances, tremble for the rights of the community. This will account for an apparent change in his sentiments towards the latter period of his life, and we hesitate not to say, that the work which exhibits

Currie.

* It may not be improper to take notice in this place, of the benevolent exertions of Dr Currie in promoting another institution more immediately connected with his profession, though, in doing so, we transgress the order of time. In the year 1785, a proposal was made to connect with the public infirmary (of which Dr Currie was one of the physicians) an asylum for the reception of lunatics. This project the doctor zealously espoused, and warmly recommended in two letters, which he published in Gore's Liverpool Advertiser in 1789, and which are stamped with the characteristic elegance and ability of his pen. The result of his labours, combined with the exertions of other benevolent individuals, was the erection of a well-planned edifice, for the reception of those who suffer under the pressure of the worst of human ills, "the mind diseased."

the most striking evidence of the qualities we have attributed to him, is the "*Letter Commercial and Political, addressed to the Right Hon. William Pitt,*" which he published under the signature of *Jasper Wilson.* This pamphlet was never indeed publicly acknowledged by him, but to his intimate friends he did not scruple to avow it, * and it was universally understood to proceed from his pen. The history of the publication, so far as we have been able to trace it, was shortly this: The commencement of hostilities having been followed by many failures in the mercantile world, it became a matter of great public importance to discover how far these failures were imputable to the war. In order to ascertain this point, a gentleman who took an active part in the political struggles of the day, addressed a private letter to Dr Currie, with whom he was in habits of friendship, and whose talents he admired, containing some queries regarding the embarrassment of commercial affairs in Liverpool, as connected with political events. Dr Currie entered into the views of his friend with his characteristic zeal and perseverance, and he soon found the result of his enquiries to be so important, and to involve consequences of such magnitude and extent, that he could not, consistently with the duty he owed to the public, confine his discoveries wholly to the bosom of private friendship. He determined, therefore, to give them to the world as a free-will offering, rejecting all regard to personal fame, which, on such a subject, he knew might be detrimental to his professional interests, and concealing his real character under the shelter of a feigned name.

Jasper Wilson's letter made its appearance in 1793, a most critical and interesting period, when the country had been newly precipitated into the war with France, and when the ferment of the public mind was at its height. We do not stop to enquire into the wisdom or folly of our government on this momentous occasion, but shall merely observe, that, independently of the elegance and energy of its language, the extent of its information, and the profundity and enlargement of its views, the work owed its uncommon success principally to the seasonableness of the argument against the war which it maintained. All the original declared objects of the first coalition against the French republic had been gained, and the Brissotine faction were at that moment actually suing for peace. The pamphlet went quickly through three editions; and whilst it acquired for its author the warmest admiration amongst the partizans of one party, raised against him a host of enemies in the other. Several answers were attempted, and one of the respondents even used the unpardonable liberty of publishing a personal attack on Dr Currie, proclaiming him to the world by name as the reputed author. The violence and illiberality of his opponents did not provoke from him any answer, but it may be interesting to know in what temper he privately listened to their invectives. With this view, we quote the following passage from a letter now before us, written by him in March 1794 to his uncle and confidential friend, Mr Duncan of Lochrutton, a Scottish clergyman, whose unaspiring modesty, confined to the useful but obscure duties of a country parish, virtues, and accomplishments, would have adorned the most exalted station. "The reputation of this work," says he, "has procured, not to *Jasper Wilson*, but to your nephew, many false and foul imputations. The ministerialists and war-mongers are a most irritable set, and cannot bear to be reasoned with. Though they are strong in numbers, they have all the peevishness of conscious weakness; and when they cannot confute, they calumniate and misrepresent. Jasper Wilson has had the honour to be answered four or five times; and at last Dr Currie is publicly addressed by a clerk † in Lord Hawkesbury's office as 'the reputed author of Jasper Wilson's letter,' in a strain of unparalleled insolence, falsehood, and malignity. Mr Vansittart, whose pamphlet you have read, is the most gentlemanlike, and the most able of his answerers **** The statement of Vansittart respecting the treaty of Pilnitz, is a poor sophistry. There were two treaties—one secret, one divulged. The secret treaty he denies, or rather gives reasons for disbelieving; but you will see in the debates of the present session, that it is admitted on all sides. Respecting the finances of our allies, time has decided in favour of Jasper Wilson's speculations. * * * * * * It is seldom that calumnies injure an honest man, unless he makes a grand stir about them. I do not open my lips either about Mr Wilson or his antagonists, and I beg the same favour of my friends. * * * * *"

The interest which Dr Currie's benevolent mind led him to take in the general welfare, he did not suffer to interfere with his professional avocations; and it was on his medical skill and acquirements that he chiefly rested his title to celebrity. His affectionate attention to his patients, and the success which attended his prescriptions, would have insured to him a high reputation as a physician, even though his labours in the science to which his chief attention was due had extended no farther. But he had earned for himself no inconsiderable share of respect by the medical papers he had already published; and in October 1797, he gave to the world a professional work of the highest merit, under the title of "Medical Reports on the effects of Water, cold and warm, as a remedy in Fever and Febrile Diseases, whether applied to the Surface of the Body, or used internally."

It was chiefly by this publication that Dr Currie obtained that very distinguished rank in the medical world which has associated his name with those of the great benefactors of our species.

It is curious to observe, to what apparently trivial occurrences we are indebted for some of the most important discoveries in science and in art. The following is the history of that which is communicated in the work before us. In the month of September 1778, young Currie, in company with a fellow-student, left Edinburgh on a pedestrian excursion to Annandale. After a walk of somewhat more than sixteen miles, the travellers arrived on the banks of the Tweed, near Peebles, and, being heated by their exercise, eagerly plunged into the stream. The delightful coolness of the water renewed their vigour, and enabled them to proceed on their journey with alacrity. They had, however, to advance sixteen miles further, towards the source of the river, before a resting-place occurred; and towards the end of this long stage, they were exhausted with fatigue, and in a state of profuse perspiration. Here Currie again descended into the water,

* In one of the London prints there appeared a formal *disavowal* of the publication inserted in Dr Currie's name; but the writer of this article knows that the disavowal was not dictated by Dr Currie, and gave him serious uneasiness.

† Mr Chalmers, author of the "Comparative Estimate," &c.

trusting that he should experience the same refreshment as the morning's bath had afforded; but the result was exactly the reverse of what he had anticipated. A feverish chill, accompanied by extreme prostration of strength, painfully instructed him that an application which, in one state of the system, is salutary, may be noxious in another. This circumstance made a deep impression on his mind, and seems to have suggested that inquiry into "the effects of cold on the living body," which formed the subject of some ingenious speculations presented by him, soon after, to the Royal Medical Society of Edinburgh, and recorded in their manuscript Transactions. The ideas elicited in the course of the debate to which this paper gave rise, confirmed the interest which the author had taken in the subject, and induced him, from that time, to observe and note down such facts as seemed to illustrate it, particularly with a view to medical practice.

Much about this period, Dr Wright communicated to the Medical Society of London the result of his experience with regard to the efficacy of ablution with cold water in some cases of fever; but the paper containing this valuable information was not published in the London Medical Journal till 1786. Dr Currie had already learned how to appreciate the discrimination and judgment of the acute and worthy author; and finding in the work a remarkable coincidence with his own sentiments, he determined to adopt the system which it recommended, especially when he found that his colleague, Dr Brandreth, had already put it to the test of experience. In a practice so extensive as Dr Currie had even then acquired, early opportunities occurred of acting upon this resolution; and personal observation confirming the theoretical speculations of this accomplished physician, he was soon enabled to improve upon the suggestions of his predecessors, and to point out the causes of apparent inconsistencies in the effects which they recorded. He proved that cold water may at all times be safely and efficaciously employed in fevers, whether externally or internally, especially at their commencement, *when there is no sense of chilliness present, when the heat of the surface is steadily above what is natural, and when there is no general or profuse perspiration.* On the observance of these rules, of which Dr Currie is universally acknowledged to be the discoverer, the efficacy, and indeed the safety of this powerful remedy, entirely depend; for if they be unfortunately overlooked, it may be converted into an instrument of speedy and inevitable death. Dr Currie enriches and supports his reasonings on the action of cold upon the human frame, by scientific illustrations from the works of the ancients, and by the detail of numerous experiments made by himself, partly on the healthy, and partly on the diseased subject, which are evidently the suggestions of a great and comprehensive mind. These experiments were varied, by combining the water employed with various proportions of caloric, and sometimes impregnating it with salt. That he might proceed with greater accuracy, and state his cases with more precision, he called in the thermometer to his aid, and for the first time shewed the importance of this useful instrument in the hands of the physician, as a measure of the patient's temperature. Having once ascertained the general principles which were to regulate the practitioner in the employment of this remedy, he proceeded successfully to extend the use of it to various diseases, in some of which it had not previously been tried. He particularly established its utility in the eruptive fever of scarlatina, a pestilent disorder, whose ravages were becoming every day more extensive, and more alarming all over Europe, until checked, as we trust they now have been, by this happy discovery.

Following the excursive propensity of genius, our author includes in his reports various interesting facts and speculations not immediately but collaterally connected with the principal object of his book. He favours us with his opinions on the nature of fever in general; on animal heat; and on perspiration. He offers us some valuable observations on insanity, and on convulsive diseases. He discusses the effect, on the human system, of opium, of ardent spirits, of antimonials, of digitalis, and of nitric acid. He investigates several other curious questions in physiology, particularly that which relates to the inhaling power alleged by many ancient as well as modern observers, to be a property of the cuticle; and he everywhere captivates the reader by the rich variety of knowledge with which the exposition of his doctrines is enlivened. From the public situation which he held in a commercial town of very great resort, his name had previously been widely circulated, and his character stood high in the public opinion as a man of talents, candour, and benevolence. His book, too, was written in a style at once popular and luminous. In its subject every family was deeply interested; the evidences which he adduced in support of his positions were incontrovertible and conclusive; and the simple but powerful means by which he proposed to effect the most important ends were already in the hands of all. It can therefore be no matter of wonder that the "Medical Reports" were eagerly read by men of all professions; that they produced general conviction of their accuracy; that the principles which they explained were instantaneously diffused over the medical world; and that they quickly effected so great a change in the established modes of treating fevers and febrile diseases, that they might fairly be said to mark a new era in the history of medicine.

Dr Currie's genius was of that comprehensive kind which does not rest satisfied with attainments in one department of science, and he had always mingled with his professional pursuits a predilection for polite literature. The memoir of Dr Bell, which had been drawn from him by the claims of friendship, sufficiently proved the superiority of his biographical powers; and, in the year 1800, he gave a new evidence of the accuracy of his taste and judgment, as well as of the versatility of his talents, and the goodness of his heart, by publishing, in four volumes octavo, "*The Works of Robert Burns, with an Account of his Life, and Criticisms on his Writings; to which are prefixed some Observations on the Character and Condition of the Scotish Peasantry.*" To this undertaking Dr Currie was invited by motives of charity. Burns, after leading a life of greater fame than prosperity, and displaying a character more remarkable for genius than virtue, had died in circumstances of penury and wretchedness which would have left an indelible stain on the reputation of his countrymen, had not the blame been more justly due to his own imprudence and folly. Dr Currie had read the works of this bard of nature with an enthusiasm heightened by an amiable feeling of nationality, which he inherited as the birthright of his countrymen; and having, in the year 1792, paid a visit to his native county, he had become personally interested in the poet's fate, by being introduced to him, and experiencing the fascination of his social powers. On Burns's death, therefore, the destitute situation of the family excited

Currie.

in the Doctor's mind a strong feeling of compassion; and when his friend, Mr Syme of Ryedale, in conjunction with other persons of taste, urged him to become editor of the works of this extraordinary man, he did not feel himself at liberty to decline the call of benevolence. The task is universally allowed to have been performed with great ability, and its success fully equalled the most sanguine expectations. Repeated editions produced a balance of profit, which formed a little fortune for the widow and children of the deceased; and Dr Currie had the satisfaction of finding himself one of the most powerful friends of departed genius which the annals of British literature record.

The severe illness which threatened Dr Currie's life at the very commencement of his medical career, had given a shock to his constitution from which he never fully recovered, and in the early part of 1804 his health began visibly to decline. During the summer months of that year he paid a visit to Scotland; and, besides the salubrity of his native air, he found, in the delightful society of his early friends, a relaxation no less gratifying to his mind than invigorating to his bodily powers. The enjoyment of this last visit to the scene of his youthful pleasures, could not fail to be greatly enhanced by the opportunity it afforded him of witnessing the happy effect of his benevolent exertions on the family of Burns; and in speaking of this journey, he always dwelt with peculiar satisfaction on a subject which was so well calculated to interest the generous heart. He returned to Liverpool apparently in a state of rapid convalescence, but this flattering prospect was not of long duration. On the re-appearance of alarming symptoms, he found it necessary, in the month of November, finally to quit the climate and business of Liverpool, where the loss of his society and of his professional skill was deeply regretted. He spent the winter alternately at Clifton and Bath; and in the month of March, thought himself in such a state of recovery as justified his commencing the practice of his profession in the latter town. The acquisition of a man of such acknowledged eminence in the healing art, was hailed by the inhabitants of Bath, and by the invalids who frequented that celebrated watering-place, as a public benefit; and his career commenced in a manner which promised the highest success. He still continued sensible, however, of the precarious situation of his health; and in a letter which the author of this memoir received from him, dated "Bath, 14th July 1805," he alludes to the subject in the following terms: "I am still very delicate, I cannot well tell you how. I am weak, and easily made breathless; but I am at present rather better than usual. I am following my profession here, and am likely enough to *die in harness*." The scene was now soon to close. All his complaints returned with new violence, and, as a last resource, he went in August to Sidmouth, where, after much suffering, which he bore with manly fortitude and pious resignation, he expired on the 31st of that month, in the 50th year of his age. His disease was ascertained to be a great enlargement of the heart, accompanied with remarkable wasting of the left lung, but without ulceration, tubercle, or abscess. He left a widow and five children, who inherit his virtues. His eldest son is settled in Liverpool as a merchant, and his eldest daughter is married to an Irish gentleman.

The following affectionate, but just and discriminating tribute to the memory of this eminent man, appeared in a provincial paper, the production of an unknown hand: "Scotland has produced few characters whose names will descend to posterity with more splendid or more merited reputation. As a physician, he possessed the entire confidence of his patient; and his industry, anxiety, and skill, were attended with wonderful success. By his medical writings, he has thrown great light on the healing art; and particularly, by his reports on the effects of water in fever, has contributed, more than any man of the age, to arrest the progress and promote the cure of the most frequent and fatal diseases. As an author, independently of his professional writings, the memoirs of his early friend Dr Bell—the celebrated letter of Jasper Wilson to Mr Pitt—and the *Life of Burns*, place him in the first rank. No one that has felt interested in the premature fate of men of genius, can be indifferent to that of him, who, with a kindred mind and an impartial hand, has traced their sublime course, their wanderings, and their errors: Who, with a true admiration of their talents and their productions, has not omitted to point out their failings as a warning to others, and to inculcate the necessity of that prudence and exertion, without which 'wit becomes ridiculous, and genius contemptible.' To dignity of manners he united a social and most sympathetic spirit; and though somewhat formal on a first introduction, no man with more readiness engaged in the discussion of scientific or general subjects, or with more grace and pleasure relaxed, in easy conversation, into sportive and playful sallies of wit. In the interesting relations of life, he was uniformly firm, tender, and affectionate. He was a steady friend of liberty—a true and enlightened patriot, tha regarded, with an interest amounting to a painful anxiety, every thing in which his country was concerned, and those great events which, of late years, have agitated the political world. He aimed at and he possessed a high and honourable fame, which, as it was the reward of his useful labours, his elegant writings, and his great virtues, will live whilst excellence is honourable amongst men, and whilst the remembrance of its sons and benefactors is cherished by a grateful country." (H. D.)

CURTISIA, a genus of plants of the class Tetrandria, and order Monogynia. See BOTANY, p. 124.

CURVE LINES AND SURFACES.

Curve Lines.

1. THE theory of curve lines, is one of the most important additions which Descartes made to the science of mathematics, by the application of algebra to geometry. Before his time, indeed, algebra had been applied to the resolution of some particular geometrical problems; but it was he that first thought of expressing the nature of curve lines by algebraic equations, and thereby laid the foundation of some of the greatest improvements that have been made in both branches of the science.

2. A curve line may be defined to be, that of which no part is a straight line. The circumference of a circle, and the conic sections, are particular instances of such lines; but there may be an endless variety.

3. A curve surface is that of which no part is a plane. The surfaces of a cone, a sphere, and a cylinder, are of this nature.

4. If a curve lie entirely in one plane, it is called a plane curve; such is the circumference of a circle. But

Curve Lines.

if it does not lie all in one plane, it is called a curve of double curvature: the oblique rhumb lines on a common terrestrial globe are curves of double curvature.

5. In the theory of plane curves, the first thing to be considered is the manner of determining and describing the situation of a point on a plane. This may be done in various ways. For example, we may estimate its distance from two given points, and then its position will be determined by the intersection of two circles described on these points as centres, with its known distances from them as radii. Or we may consider how far the point is from a given point, and also from a straight line given by position, and either of these methods will apply with advantage to the describing of the conic sections; for it has been shewn, that the ellipse and hyperbola are lines of such a nature, that the sum of the distances of any point in the former curve, and their difference in the latter from two fixed points, is always a constant line; also, that the distance of every point in any of the three sections from a given point, has to its distance from a given line a given ratio. These methods, however, would not be found to be generally convenient, and therefore their application is limited to the particular curves referred to.

6. There are, however, two other methods of general and easy application. By the first, the situation of a point is determined by its distances from two straight lines, having given positions, and intersecting each other, (commonly at right angles,) just as the position of a point on the earth's surface is determined by its latitude and longitude; and by the second method, the position of a point is determined by its distance from a fixed point, and the angle which a line, drawn from it to that point, makes with a line given by position passing through the same point. We shall be most particular in explaining the first of these methods, or rather that method rendered somewhat more general, because the transition from it to the second is easy.

Plate CCXXVII. Fig. 2.

7. Let us suppose then, that xAX and yAY, Fig. 2, are two straight lines given by position, intersecting each other at any point A, and let M be any point in their plane. Draw MP, MQ parallel to AX, AY, meeting them in P and Q. The point M is manifestly determined, if we know the lines AP and AQ, and their directions in respect of the point A. The lines AX, AY produced indefinitely, are called the *axes*. The line AP, the segment of one of the axes intercepted between a line drawn from M parallel to the other axis, is called the *abscissa* of the point M; and the line PM or AQ is called its *ordinate*. The line AX is called the axis of the abscissæ; and AY that of the ordinates. It is a matter of indifference which of the two axes is taken for that of the abscissæ. Any abscissa, and its ordinate, are commonly called *co-ordinates*. The point A, from which the co-ordinates are reckoned, is called their *origin*. It is usual to denote any abscissa by x, and the corresponding ordinate by y, and to call AX the axis of x, and AY the axis of y.

8. If the two indeterminate lines AP, PM, or x and y, be supposed to have, for a certain position of the point M, the values

$$x=a,\ y=b,$$

as by these equations the position of the point is determined, we may call them *the equations* of the point.

The abscissa AP being supposed to remain the same, if the ordinate PM decrease, the point M will approach to the axis AX, so that PM, or b, becoming at last $=0$, M will fall on P; therefore the equations of any point P in the axis of the abscissa are of this form, $x=a$, $y=0$. If we now suppose the ordinate PM to remain the same and the abscissa AP to decrease, then M will approach to AY, so that at last QM vanishing, we have $x=0$, $y=b$, for the equation of any point in the axis of the ordinates.

Lastly, If we suppose both AP and PM to decrease, and vanish at the same time, then we have $x=0$, $y=0$, for the equation of the origin of the co-ordinates. We may therefore conclude, that by giving to x and y all possible values from 0 to infinity, we can indicate the position of every point whatever in the angle YAX.

9. That we may see how the position of a point in any of the other three angles made by the axes is to be indicated, let us suppose, that instead of AY, another line A′Y′, Fig. 3, parallel to the former, is taken for the axis of the ordinates. Let A=AA′, and let x' be the new abscissa, taken on the same axis AX, but reckoned from the new origin A′. If we now consider any point M, situated in the angle YAX, we have AP=AA′+A′P, or $x=A+x'$. But if we consider a point M′ situated in the angle Y′A′A, and still represent its abscissa A′P′ by x', which denotes a variable quantity of any magnitude whatever, we have AP′=AA′—A′P′, or $x=A-x'$; from which it appears, that if we wish to render the same analytical formula $x=A+x'$, applicable at once to points situated in the angle XA′Y′, and to points in the angle AA′Y′, we must for these last regard the values of x' as negative, so that the change of sign answers to their change of position with respect to the axis A′Y′. Plate CCXXVII. Fig. 3.

10. To confirm this result, and shew more clearly how the preceding formula may connect the different points of a plane, let us consider a point situated in the axis A′Y′ itself; then x' vanishes, and the formula $x=A+x'$ gives $x=A$; and this is the value of the abscissa AA′ with respect to the axes AX, AY. But if we wish that the same equation apply to points in the axis AY, let us consider any one point in that line; it is evident that its abscissa x is equal to 0, and therefore the preceding formula gives $A+x'=0$, or $x'=-A$, which is the value of the abscissa AA′ supposing it referred to the axis A′Y′. The analytic expression of this formula becomes therefore positive for the axis AY, and negative for the axis A′Y′, when the points of the plane are supposed connected by the equation $x=A+x'$. This result applies equally to negative values of x, and proves that they belong to points situated on the side of the axis AY, opposite to that on which the positive values are taken: For M″ being supposed any such point, we may always draw a new axis A″Y″, which has the same relative position in respect of AY as this last had in respect of the axis A′Y′.

11. By removing the axis AX parallel to itself, and fixing the new origin at A″, (Fig. 4,) making AA″=B, and putting y' for the new ordinates, reckoned from the axis A″X″, we shall have $y=B+y'$ for the points situated in the angle YA″X″, and $y=B-y'$ for those in the angle AA″X″; so that to comprehend both in the same analytic formula, the negative values of y' must be considered as corresponding to points situated on the side of the axis A″X″, opposite to that on which the positive values lie; and as this applies equally to the axes AX, AY, we may conclude, that the change of the sign of the variable line y, answers to a change of position of the points from one side of the axis of the abcissæ to the other. Fig. 4.

12. Upon the whole, it appears that the negative values of the co-ordinates must be taken in a direction the opposite to that of their positive values, otherwise the same formula cannot be applied to all the points of a plane, but will only comprehend the points situated in

Curve Lines.

the one angle of the axes. On the other hand, this conventional hypothesis being assumed, all the points in a plane, whatever be their position, may be comprehended in the same formula. Accordingly (Fig. 2.)

in the angle YAX, x is positive and y positive;
in the angle YAx, x is negative y positive;
in the angle XAy, x is positive y negative;
in the angle x A y, x is negative y negative;

consequently the equations $x=a$, $y=b$, which determine the position of a point in the angle YAX, become

$$x=-a \quad y=+b$$
$$x=+a \quad y=-b$$
$$x=-a \quad y=-b$$

according as the point shall pass into one of the angles YAx, XAy, xAy. By supposing a and b to be any quantities, positive or negative, the two first may represent all the others.

13. Every line that can be traced by a point moving according to some determinate law on a plane, may always be referred to two axes. The nature of such a line being expressed by some common property which belongs to all its points, that property will, in every case, furnish an equation expressing a common relation between the co-ordinates at any point whatever in the line, and as this equation will be characteristic of the line, it may be called *the equation* of the line.

Plate CCXXVII. Fig. 5.
14. As a particular example, let us consider the straight line BA′M, (Fig. 5.) which meets the axes AY, Ax in A′ and B. Then MP being drawn from any point in the line parallel to AY, we have, agreeably to the notation, AP$=x$, PM$=y$. Let us denote generally the segments which the line MA′B cuts off from the axes Ax, AY by a and b, giving to a and b the signs which belong to them from their position in respect of the origin A. In the Figure under consideration, we must, agreeably to what has been said, make AB$=-a$ and AA′$=+b$.

By the nature of a straight line, PM has to PB a given ratio. This property gives immediately $y=\text{H}x+\text{K}$ for the general equation of the line, H and K being put for invariable quantities. To determine H and K, it is to be observed, that when $x=0$, then $y=b$, and that when $y=0$, then $x=-a$, therefore in these two particular cases the general equation becomes $b=0+\text{K}$, $0=-a\text{H}+\text{K}$, hence we find $\text{K}=b$ and $\text{H}=\frac{\text{K}}{a}=\frac{b}{a}$, and thus the equation of the line is $y=\frac{b}{a}x+b$.

If α be put for the angle B which the straight line makes with AX the axis of the abscissæ, and β for the angle A contained by the axes AX, AY, then in the triangle AA′B, we have A′$=\beta-\alpha$, and since, by Trigonometry, $\frac{b}{a}=\frac{\text{Sin.}\ \alpha}{\text{Sin.}\ (\beta-\alpha)}$, the general equation of a straight line may also be expressed thus,

$$y=\frac{x\ \text{Sin.}\ \alpha}{\text{Sin.}\ (\beta-\alpha)}+b.$$

If we suppose the axes at right angles to one another, then Sin. $(\beta-\alpha)=$ Cos. α, and in this case $y=x$ Tan. $\alpha+b$. Each of these equations gives a positive value of y for every positive value whatever of x, and also for all negative values between $x=0$, and $x=-a$; but for every negative value of x beyond $-a$, we find that y is also negative; by which it appears, that the nature of a straight line, as well as the circumstance of its passing through the three *regions* YAX, YAx, xAy, are correctly indicated by its general equation.

Fig. 6.
15. To find a general equation for a circle in respect of two rectangular axes, let AB and BO, the co-ordinates of its centre, Fig. 6. (which we shall suppose situated in the angle YAX,) be denoted by a and b, and put c for its radius. From M any point in the circumference draw MF perpendicular to BO; then supposing x and y to be co-ordinates of M, we have PB$=$MF$=a-x$, and FO$=b-y$, and since MO$^2=$MF$^2+$FO^2, we have for the equation of the circle,

$$(a-x)^2+(b-y)^2=c^2,$$
$$\text{or, } x^2+y^2-2ax-2by=c^2-a^2-b^2.$$

If the origin of the co-ordinates be at the centre, then $a=0$, $b=0$, and the equation is simply $x^2+y^2=c^2$.

Plate CCXXVII. Fig. 7.
16. To find the equation of any conic section HMK referred to the rectangular axes AX, AY; let F be a focus, (Fig. 7.) OD the directrix, and AO its distance from A. Put AO$=d$, and let AC and CF, the co-ordinates of the focus, be denoted by a and b; and let α denote the angle which the axis of the conic section makes with AX the axis of the abscissæ. The lines AP$=x$ and PM$=y$ being the co-ordinates of any point M of the curve, draw PBI parallel, and MDB perpendicular to the directrix; also ME perpendicular to FC. The angles IAP, BPM, are manifestly each $=\alpha$; therefore

$$\text{AI}=\text{AP}\times\text{Cos.}\ \alpha=x\ \text{Cos.}\ \alpha,$$
$$\text{MB}=\text{MP}\times\text{Sin.}\ \alpha=y\ \text{Sin.}\ \alpha,$$

and hence MD$=y$ Sin. $\alpha+x$ Cos. $\alpha-d$. Moreover, in the right angled triangle MEF, we have

$$\text{MF}^2=\text{ME}^2+\text{EF}^2=(a-x)^2+(b-y)^2.$$

Let the determining ratio of the conic section be that of 1 to n; then because $1 : n^2 :: \text{FM}^2 : \text{MD}^2$ (See Conic Sections,) we have MD$^2=n^2\times$FM^2; in this expression substitute the values of FM^2 and MD^2, and we get

$$(y\ \text{Sin.}\ \alpha+x\ \text{Cos.}\ \alpha-d)^2=n^2\left\{(a-x)^2+(b-y)^2\right\}$$

for the equation of the conic section, and which, by putting

$\text{A}=n^2-\text{Sin.}^2\ \alpha$; $\quad \text{D}=2d\ \text{Sin.}\ \alpha-2n^2b$;
$\text{B}=-2\ \text{Sin.}\ \alpha\ \text{Cos.}\ \alpha$; $\quad \text{E}=2d\ \text{Cos.}\ \alpha-2n^2a$;
$\text{C}=n^2-\text{Cos.}^2\ \alpha$; $\quad \text{F}=a^2+b^2-d^2$;

may also be expressed thus,

$$\text{A}y^2+\text{B}xy+\text{C}x^2+\text{D}y+\text{E}x+\text{F}=0.$$

17. From the values of A, B, C, we find that

$$4\text{AC}-\text{B}^2=4n^2(n^2-1).$$

This property of the coefficients deserves attention, because it affords a criterion by which the kind of section to which the equation belongs may be immediately determined. Thus, if $4\text{AC}-\text{B}^2$ be a positive quantity, n must be greater than 1, and the section must be an ellipse. (See Conic Sections.) If, again, $4\text{AC}-\text{B}^2=0$, then $n=1$, and the section is a parabola; and lastly, if $4\text{AC}-\text{B}^2$ be negative, n must be less than 1, and the section is a hyperbola.

Fig. 8.
18. In the analysis of curve lines, it is often necessary to change the direction of the axes, as well as the origin of the co-ordinates, that is, to refer the curve to two new axes. The object of this change, in general, is to render the equation of a curve more simple in its form. Let us first suppose that the origin is to be changed, so that AX, AY (Fig. 8.) being the original position of the axes, they may have a new position A′X′, A′Y′, parallel to their former position. Let AB, BA′, the co-ordinates of A′, the new origin in respect of the original axes, be a and b; and supposing AP, PM, the co-ordinates of a point M, referred to the original axes to be x and y; let their new values A′P′, P′M be x' and y'. Then, because from the position of the lines, AP$=$AB$+$BP, PM$=$BA′$+$P′M, we have $x=x'+a$, $y=y'+b$. These values of x and y being substituted in the equation of any curve, it will be transformed into another, expressing the relation of x' to y', the new co-ordinates.

Curve Lines.

In the Figure, we have supposed the new origin A′ to be in the angle XAY, in which a and b are both to be accounted positive; if it had been in one of the other three angles, we must, in like manner, have given to a, b, the signs which belonged to that angle. Thus, in the angle XAy, a would have been positive and b negative; so that we should have had $x=x'+a$, $y=y'-b$.

Plate CCXXVII. Fig. 9.

19. Having given the relation of $AP=x$ (Fig. 9.) and $PM=y$, the co-ordinates of a point M, referred to the axes AX, AY; let it be required to find the relation of $AQ=x'$, and $QM=y'$, the co-ordinates of the same point referred to other two axes AX′, AY′, having a given position in respect of the former, the origin of the co-ordinates A being supposed in both cases the same.

Put $\beta=XAY$, the angle which the axes make in their original position, also $\alpha=X'AX$, and $\alpha'=Y'AX$, the angles which the new axes make with AX, the original axis of the abscissæ. Draw QKI parallel to AX, meeting PM in K, and QL parallel to AY; then $MKI=\beta$, $AQL=\beta-\alpha$, and $QMK=\beta-\alpha'$. In the two triangles ALQ, QKM, we have, by trigonometry,

$$\text{Sin. }\beta : \text{Sin. }(\beta-\alpha) :: x' : AL,$$
$$\text{Sin. }\beta : \text{Sin. }\alpha :: x' : LQ=PK,$$
$$\text{Sin. }\beta : \text{Sin. }(\beta-\alpha') :: y' : QK=LP,$$
$$\text{Sin. }\beta : \text{Sin. }\alpha' :: y' : KM.$$

Hence,
$$AL\times\text{Sin. }\beta=x'\text{ Sin. }(\beta-\alpha),$$
$$LP\times\text{Sin. }\beta=y'\text{ Sin. }(\beta-\alpha')$$
$$PK\times\text{Sin. }\beta=x'\text{ Sin. }\alpha,$$
$$KM\times\text{Sin. }\beta=y'\text{ Sin. }\alpha';$$

and since by the position of the lines, $AP=AL+LP$, $PM=PK+KM$, we have

$$\left.\begin{aligned} x&=\frac{x'\text{ Sin. }(\beta-\alpha)+y'\text{ Sin. }(\beta-\alpha')}{\text{Sin. }\beta}\\ y&=\frac{x'\text{ Sin. }\alpha+y'\text{ Sin. }\alpha'}{\text{Sin. }\beta}\end{aligned}\right\}\ldots.(1.)$$

These values of x and y being substituted in the equation which expresses the relation of x to y, the result will be a new equation, expressing the relation of x' to y'.

In applying these formula to any particular case, regard must be had to the position of the new axes AX′, AY′, in respect of the former. Thus, if the new axes of the abscissæ were to have the position AX″ on the other side of AX′, then, instead of $\beta-\alpha$, we would have $\beta+\alpha$; and, in this case also, Sin. α must be reckoned as negative.

20. If the original axes contain a right angle, then Sin. $\beta=1$, Sin. $(\beta-\alpha)=$ Cos. α, Sin. $(\beta-\alpha')=$ Cos. α'; and, in this case,

$$\left.\begin{aligned} x&=x'\text{ Cos. }\alpha+y'\text{ Cos. }\alpha'\\ y&=x'\text{ Sin. }\alpha+y'\text{ Sin. }\alpha'\end{aligned}\right\}\ldots.(2.)$$

Again, supposing the original axes to contain a right angle, if the new axes also contain a right angle, in this case, $\alpha'-\alpha=90^0$, or $\alpha'=90^0+\alpha$, and Sin. $\alpha'=$ Cos. α, Cos. $\alpha'=-$Sin. α. See Arithmetic of Sines.

Hence these last formulas give us

$$\left.\begin{aligned} x&=x'\text{ Cos. }\alpha-y'\text{ Sin. }\alpha\\ y&=x'\text{ Sin. }\alpha+y'\text{ Cos. }\alpha\end{aligned}\right\}\ldots.(3.)$$

Examples of the application of these formulas to the transformation of equations, may be found in the concluding section of Conic Sections.

21. Let us now consider the other mode mentioned in Art. 6. by which the position of a point, or the nature of a line described on a plane, may be indicated.

Fig. 10. Let HK (Fig. 10.) be any line whatever. Assume AX a straight line, having a determinate position in the plane of HK, and take A, a given point in AX. If now, from M, any point in HK, a straight line MA be drawn to A, and we put r for AM, and φ for the angle MAX, it is evident that the position of M will be determined, if the line r and the angle φ are both known, and therefore that the nature of the line HK will be indicated by an equation expressing the relation between r and φ.

Curve Lines.

By supposing the line AM to revolve about A as a pole, such a relation between r and φ may be assigned as shall determine its extremity M to describe any proposed curve. In this mode of generating curves, the angle φ, or the arc of a circle described on A as a centre with a radius $=1$, which serves to measure that angle, may be regarded as an *abscissa*, and the corresponding line r as the *ordinate*. The two are commonly called *polar co-ordinates* of the line HK; and the equation expressing the relation of φ to r, its *polar equation*.

22. It is easy to pass from the equation of a curve referred to two rectilineal axes, to its polar equation. For let AX, AY be rectangular axes passing through the pole A; and let $x=AP$, $y=PM$; then, by trigonometry, we have

$$x=r\text{ Cos. }\varphi,\ y=r\text{ Sin. }\varphi.$$

These values being substituted in the equation of the rectangular co-ordinates of a curve, it will immediately be transformed to its polar equation.

Thus the equation of a circle, viz.

$$x^2+y^2-2\,ax-2\,b\,y=c^2-a^2-b^2$$

gives us, for its polar equation,

$$r^2-2r\,(a\text{ Cos. }\varphi+b\text{ Sin. }\varphi)=c^2-a^2-b^2.$$

The most simple polar equations of the conic sections, are given towards the conclusion of the article Conic Sections.

The polar equation of a curve being given, we may, on the contrary, find the equation of its rectangular co-ordinates. To do this, it is only necessary to put $\frac{x}{r}$ for Cos. φ, and $\frac{y}{r}$ for Sin. φ, and afterwards to put $\sqrt{(x^2+y^2)}$ for r.

23. As there may be an endless variety of lines, in considering their relations one to another, it has been found necessary to class them. Accordingly, they have been divided, in the first place, into two kinds.

1. Such as may have their nature indicated by an equation of a finite number of terms, composed of integral powers of the indeterminate quantities x, y, (co-ordinates to two rectilineal axes,) and given quantities. Lines of this kind are called *algebraic*, also *geometrical*. Any straight line, a circle, and the conic sections, are particular examples of this kind of line.

2. Such lines as do not admit of their equations being expressed by a finite number of terms composed of integral powers of x, y, and known quantities. These are called *transcendental* curves, and sometimes, though improperly, *mechanical* curves. The cycloid is a curve of this kind; its equation may be deduced from these two,

$$x=a\,(1-\text{Cos. }\varphi),\ y=a\,(\varphi+\text{Sin. }\varphi),$$

by eliminating φ, and its functions Sin. φ, Cos. φ; but it will then necessarily consist of an infinite number of terms. Such curves also as have their equations of these forms, $y=a^{\frac{x}{n}}$, $y=x^{\frac{x}{n}}$, &c. are transcendental. They are also sometimes called *exponential* curves.

24. As algebraic curves still admit of an infinite variety, they have been divided into classes; and all lines whose equations are of the same degree in respect of the indeterminate co-ordinates x and y, constitute a class, or order, of the degree of the equation. The foundation of this mode of classification is the analytical fact, that *the degree of the equation of a curve cannot be changed by any change in the position of its axes.*

We have seen, (Art. 18.) that the origin of the co-ordinates is changed by making

$$x=a+x',\ y=b+y',$$

the new axes being supposed parallel to the former, and next that the direction of the new axes may be changed (Art. 19.) by taking

$$x'=m\,x''+n\,y'',\ y'=m'\,x''+n'\,y'',$$

a, b, m, m', n, n' being given quantities; therefore, to change both the origin and the position of the axes at once, we have only to assume

$$x=a+m\,x''+n\,y'',\ y=b+m'\,x''+n'\,y''.$$

But these values of x and y, when substituted in any equation in which x and y are the variable quantities, will always produce another equation of the very same degree, and having x'' and y'' for its variable quantities; and hence it happens, that by no transformation can the degree of the equation of a curve be changed.

25. A line of the first order, has its equation of the form

$$a+b\,x+c\,y=0;$$

this class consists of the straight line only. Lines of the second order, or curves of the first order, have their equations of the form

$$a+b\,x+c\,y+d\,x^2+e\,x\,y+f\,y^2=0.$$

This order comprehends four species, viz. the circle, the ellipse, the parabola, and hyperbola; or the two first may be considered as one species.

Lines of the third order, or curves of the second order, have for their equation

$$\left.\begin{array}{l} a+b\,x+c\,y+d\,x^2+e\,x\,y+f\,y^2 \\ +g\,x^3+k\,x^2\,y+i\,x\,y^2+k\,y^3 \end{array}\right\}=0.$$

This order may consist of more or fewer species, according to the principle of classification that is assumed. Newton, adopting one principle, subdivided them into 72 species; but to these, six have been added by Mr Stirling and Mr Stone. Euler, again, following another principle, has comprehended them in 16 general species; these, however, admit of being divided into many varieties: and Cramer, taking a different view of the subject, makes 14 classes.

Lines of the fourth order, or curves of the third order, have for their general equation

$$\left.\begin{array}{l} a+b\,x+c\,y+d\,x^2+e\,x\,y+f\,y^2 \\ \quad +g\,x^3+h\,x^2\,y+i\,x\,y^2+k\,y^3 \\ +l x^4+m x^3 y+n x^2 y^2+p x y^3+q y^4 \end{array}\right\}=0.$$

The lines expressed by this equation have been divided by Euler into 146 classes; and by Warring they have been comprehended in 12 cases of equations. The various species of curves, however, into which this order may be divided, amount to many thousands, and have never been distinguished individually. As to the fifth and higher orders, their number has precluded any attempt to arrange them in classes.

26. When the terms of an equation of any degree are put $=0$, if it represent a curve of that degree, it ought not to admit of being resolved into factors, which are rational in respect of x and y. If it does admit of such resolution, then each factor put $=0$ is the equation of a curve of any inferior degree, the co-ordinates of which satisfy the general equation.

The equation

$$a\,y-a\,x+x^2-2\,x\,y+y^2=0,$$

which is of the second degree, is the product of $x-y$ and $x-a-y$, so that it may be expressed thus,

$$(x-y)\,(x-a-y)=0.$$

This equation is satisfied either by making $y=x$, or $y=x-a$, and y can have no other values; now, these equations belong to two straight lines, therefore any co-ordinates of either of the two lines will satisfy the equation $a\,y-a\,x+x^2-2\,x\,y+y^2=0$, and consequently it does not represent a line of the second order, but two lines of the first order.

In like manner the equation

$$\left.\begin{array}{l} y^3-y^2\,x+y\,x^2-x^3 \\ +a\,y^2-2a\,x\,y+3\,a\,x^2-2\,a^2\,x \end{array}\right\}=0,$$

has the appearance of belonging to a line of the third order: but as it is the product of the two equations,

$$y-x+a=0,\ y^2-2\,a\,x+x^2=0,$$

the former of which belongs to a straight line, and the latter to a circle. The above equation of the third degree belongs at once to a straight line and a circle, and it cannot represent any other line.

27. From the connection which subsists between curve lines and equations, they may be reciprocally applied to the illustration of one another. As the nature of every curve generated according to some determinate law, may be expressed by an equation peculiar to that curve; so, on the other hand, corresponding to every equation involving two indeterminate quantities, there is a plane curve, the co-ordinates of which are the geometrical representatives of the variable quantities of the equation; so that all the circumstances regarding the latter are, as it were, graphically exhibited to the eye by the former.

28. The line, the co-ordinates of which represent the indeterminate quantities of any equation, is called the *locus* of the equation. The locus of an indeterminate equation of the first degree, is therefore a straight line; and that of an equation of the second degree is a conic section.

29. The position, the figure, and course of a curve, are known, when we can determine the points through which it passes. This may be done, by supposing one of the co-ordinates, as x, to have all possible successive known values, and by determining from these the corresponding values of y. Let the former be a, a', a'', &c. and the latter b, b', b'', &c. then the points whose equations are $x=a,\ y=b;\ x=a',\ y=b';\ x=a'',\ y=b''$, &c. will all be in the curve which is the locus of the equation, and may be readily found.

The determination of the points of a curve in this manner requires the resolution of its equation, which cannot in every case be effected; as, however, we can always find approximate values of the roots, the finding of the points of a curve is subject to no other difficulty than the labour of calculation.

30. As the co-ordinates of a curve admit of being the representatives of the roots of an equation, the properties of the latter will also belong to the former. It is upon this principle that the modern analysis has been applied with such success to the investigation of the various affections of geometrical figures; and these, in their turn, have been employed in illustrating some of the more intricate theories of pure analysis.

31. It is a fundamental proposition in analysis, that an equation of any degree may have as many real roots as there are units in the exponent of the highest power of the unknown quantity: hence it follows, that if the equation of any curve be resolved, so as to express the value of one of the co-ordinates in terms of the other; corresponding to any given value of the latter, the former may have as many values as there are units in its highest power contained in the equation; and this will be true, whatever angle the co-ordinates make with one another. This is an important proposition in the theory of curve lines; and from it we learn, that *a straight line cannot cut a line of any order in more points than there are units in the number expressing that order.* That this is true of the straight line and conic

Curve Lines.

sections, we know from geometrical principles, (see GEOMETRY and CONIC SECTIONS); for a straight line cannot cut another straight line in more than one point, nor a conic section in more than two.

32. Although, generally speaking, a straight line may cut a line of any order in as many points as there are units in the number expressing its order, yet this will not always be the case; the roots of an equation may be impossible, and then they can have no geometrical expression.

33. As the roots of an equation become always impossible in pairs, so the intersections of a curve and its ordinate must vanish in pairs, if any vanish. Let PM (Fig. 11.) cut the curve in the points M and m, if it be supposed to move parallel to itself, so as at last to touch it in the point M′, then the two points of intersection M, m go into one point of contact M′. The line being supposed to continue its motion, it falls entirely without the curve, and there is no contact.

PLATE CCXXVII. Fig. 11.

34. As all equations of an odd degree, viz. the third, fifth, seventh, &c. have at least one real root, the equations of lines of the same orders will give at least one real value of y for every value of x: Now, x may increase indefinitely in both directions from the origin of the co-ordinates; therefore, such a curve will have at least two infinite arcs.

Again, as the roots of equations of even degrees, viz. the second, fourth, &c. may be possible only within certain limits, so, in curves of these orders, the values of x, which give real values of y, may be confined within certain limits, and hence the curve may be contained within certain bounds, so as to have the figure of an oval.

35. When two values of y are equal, the ordinate either touches the curve, or meets it in what is called a *Punctum Duplex;* two of its arcs intersecting each other in that point; or else some oval belonging to that kind of curve becomes infinitely little at the top of the ordinate, forming there a *Punctum Conjugatum.*

If in the equation of the curve y be made $=0$, the roots of the equation by which x is determined will give the distances of the points where the curve meets the axis of the abscissæ from the origin. If two of these roots are equal, the axis touches the curve, or passes through a *punctum duplex* in the curve: When $y=0$, if one of the values of x then vanish, the curve in that case passes through the origin; but if two vanish, the axis either touches the curve, or the origin of the co-ordinates is a *punctum duplex.*

36. In order to illustrate these observations, we shall now shew, by particular examples, how the figure of a curve may be determined from its equation.

Let the equation of the curve be $y^2=ax+ab$. In this case $y=\pm\sqrt{(ax+ab)}$. By giving particular values to $AP=x$ (Fig. 12.) and substituting for a and b their numeral values, we may find any number of values of $PM=y$, and thence any number of points M, M′, &c. in the curve: and as for every value of x, y has two values, one positive and the other negative; corresponding to each, there will be two points M, m at equal distances from the axis AX, and on opposite sides of it. The greater x is taken, the greater is $\sqrt{(ax+ab)}=y$; if x be supposed infinitely great, y is also infinitely great, so that the curve has two infinite arcs, which go off to an infinite distance from the axis AX. If we suppose $x=0$, then $y=\pm\sqrt{ab}$; from which it appears that y does not vanish, and therefore the curve does not pass through A the origin of the co-ordinates, but meets the axis YAy in two points D, d, so that $AD=Ad=\sqrt{ab}$.

Fig. 12.

Suppose now that P moves to the other side of A, so that $x=AP'$ is to be accounted negative; then $P'M'=y=\pm\sqrt{(ab-ax)}$; here y has two values as before, as long as x is less than b; when $x=b$, then $y=\pm\sqrt{(ab-ab)}=0$, so that the curve passes through B, a point in Ax, such, that $AB=b$. If P be supposed to move beyond B, so that $x>b$, then $ab-ax$ being negative, $y=\pm\sqrt{(ab-ax)}$ becomes imaginary, that is, beyond B, there are no ordinates that meet the curve; and consequently, on that side, the curve is limited at B. All this agrees with what is known by the theory of the conic sections; for the curve is evidently a parabola, whose vertex is B, and axis BAX, and the parameter of the axis $=a$. See CONIC SECTIONS.

36. Let the equation of the curve be $xy+ay+cy=bc+bx$: In this case, $y=\frac{bc+bx}{a+c+x}$; and as y has only one value, corresponding to every value of x, the ordinate $PM=y$ (Fig. 13.) can meet the curve only in one point: When $x=0$, then $y=\frac{bc}{a+c}$, so that the curve does not pass through A, the origin: If x be supposed to increase, then y increases, but never becomes equal to b, because $y=b\frac{c+x}{a+c+x}$, and $a+c+x$ is always greater than $c+x$. If x be supposed infinite, then the quantities a and c are to be accounted as nothing in respect of x; and in this case $y=b\frac{x}{x}=b$, from which it appears, that taking $AD=b$, and drawing DG parallel to AX, it will be an *Assymptote,* and touch the curve at an infinite distance.

PLATE CCXXVII. Fig. 13.

If x be now supposed negative, and AP′ be taken on the other side of A, then shall $y=b\frac{c-x}{a+c-x}$, and if x be taken on that side, $=c$, then $y=\frac{0}{a}=0$, so that if $AB=c$, the curve must pass through B.

If x become greater than c, then will $c-x$ become negative, and the ordinate will be negative, and be on the other side of the axis, till x becomes equal to $a+c$, and then $y=b\frac{-a}{0}$, that is y is infinitely great, so that if AK be taken $=a+c$, the ordinate KL will be an assymptote to the curve.

If x be taken greater than $a+c$, or AP″ greater than AK, then $c-x$ and $a+c-x$ become both negative, and consequently $y=b\frac{x-c}{x-a-c}$ becomes positive; and since $x-c$ is always greater than $x-a-c$, it follows that y will be always greater than b or KG, and consequently the rest of the curve lies in the angle FGH; and as x increases, since the ratio of $x-c$ to $x-a-c$ approaches continually to a ratio of equality, it follows that PM approaches to an equality with PN, and the curve approaches to its assymptote GH, on that side also. This curve is the common hyperbola.

Curve Surfaces.

37. The theory of curve surfaces, and of lines of double curvature, follows next in order that of plane curves. This is a subject, however, of great extent; and to enter upon it at any considerable length would require more room than the limits of our work will allow. We shall, therefore, give a very brief sketch of some of the principles of this branch of geometry.

38. The position of any point in space is determined, when we know the directions and the lengths of three straight lines, drawn from the point parallel to three planes, and terminated by them. For greater simpli-

Curve Surfaces.

Plate CCXXVII. Fig. 14.

city, we may suppose the planes at right angles to one another; then, if they be represented by YAX, XAZ, YAZ, (Fig. 14.) and if it be known that a point M is placed at the distance MM′ from the first, MM″ from the second, and MM‴ from the third, it follows, from the property of parallel planes being every where equally distant from one another, that if three planes M‴MM″, M‴MM′, M″MM′, be drawn parallel to the former, at the given distances from them, the point M will be found at their mutual intersection.

39. The rectangular planes YAX, YAZ, XAZ, to which the points of space are referred, are called the *Co-ordinate planes.* They cut each other, two and two, in the directions of three straight lines, AX, AY, AZ, which pass through the same point A, and are perpendicular to one another.

40. From the nature of parallel planes, the distance MM′ may be measured on the line AZ, and is equal to AR; in like manner, the distance MM″ may be measured on the line AY, and is equal to AQ; and, lastly, the distance MM‴ may be measured on AX, and is equal to AP.

41. The straight lines AZ, AY, AX, upon which the distances of the point M from the planes are reckoned, are called the *axes* of the *co-ordinates*, and the point A is called the *origin.* The line AP=MM‴, the distance of M from the plane, which is perpendicular to AX, may be denoted by x; and similarly, the line AQ=MM″, the distance of M from the plane perpendicular to AY, may be expressed by y; and the line AR=MM′, the distance of M from the plane perpendicular to AZ, by z.

If, therefore, the three distances, AP, AQ, AR, are found to be a, b, c, we have to determine the position of the point M, these three equations,

$$x=a,\ y=b,\ z=c;$$

and as they suffice for that purpose, they may be called the *equations of the point* M.

The positions of the points M′, M″, M‴, which are called the *projections* of the point M on the three coordinate planes, are determined by these equations, for we have $y=b$, $x=a$, for the co-ordinates of the point M′, the projection of M upon the plane YAX; also, $x=a$, $z=c$, for the co-ordinates of M″, the projection of the point M on the plane XAZ; and $z=c$, $y=b$, for the co-ordinates of M‴, the projection of the point M on the plane ZAY. From the nature of these equations, it is evident that any two of them being known, the third is also known.

42. It follows from what has been said, that all the points of space being referred to three planes perpendicular to one another, the points of each plane may be naturally referred to two straight lines perpendicular to one another, which are the intersections of that plane with the two others. Thus, if each plane be denoted by the co-ordinates which belong to it, the plane YAX shall be that of x and y; the plane XAZ that of x and z; and the plane ZAY that of y and z.

43. Whatever has been said (Art. 9.—11.) respecting the signs of the co-ordinates of plane curves, applies equally here to the axes AX, AY, AZ; and it follows that the signs of the co-ordinates, x, y, z, shew the position of every point whatever in respect of the co-ordinate planes, it being understood that these are indefinitely extended, and that the straight lines AX, AY, AZ, are each produced indefinitely both ways from A, the common origin.

Agreeably to this conventional mode of representing the position of a point in space, according as it is in one or other of the eight angles which have their common vertex at A, the signs of its co-ordinates will be as follows:

$+x$, $+y$, $+z$, in the angle AXYZ,
$+x$, $+y$, $-z$, in the angle AXYz,
$+x$, $-y$, $+z$, in the angle AXZy,
$-x$, $+y$, $+z$, in the angle AYZx,
$+x$, $-y$, $-z$, in the angle AXyz,
$-x$, $+y$, $-z$, in the angle AYxz,
$-x$, $-y$, $+z$, in the angle AZxy,
$-x$, $-y$, $-z$, in the angle Axyz.

44. Let M be any point in a surface of a known nature, and which is referred to the three planes AM′, AM″, AM‴; We may suppose MM‴$=x$ and MM″$=y$, its distances from two of the planes, to have any magnitudes that admit of the point M being on the surface, and corresponding to these, MM′$=z$, its distance from the third plane, will have a magnitude, depending on the nature of the surface; therefore the value of z depends jointly on the values of x and y, so that these being known, z is also known.

The equation which expresses the relation of z to x and y is called the *equation* of the *surface*: so that like as the nature of a line on a plane may be expressed by an equation involving two indeterminate quantities, the nature of a surface may, in general, be expressed by an equation containing three indeterminate quantities.

45. The position of a point M being given in space by its co-ordinates x, y, z, its distance MA from A the origin is known. For we have $AM^2=AM'^2+M'M^2=AP^2+PM'^2+M'M^2=x^2+y^2+z^2$. Hence also the co-ordinates of any two points being given, their distance is known; for let x', y', z', be the co-ordinates of the second point, and let us suppose the co-ordinate planes to be transferred parallel to themselves, so that the origin may be at the first point; then the new co-ordinates will be $x'-x$, $y'-y$, $z'-z$, and the distance of the second point from the new origin, that is from the first point, will be

$$\sqrt{\left\{(x'-x)^2+(y'-y)^2+(z'-z)^2\right\}}$$

46. The equation of a plane may be readily found from the analytical expression for the distance between two points, by considering it as a surface, every point of which is equally distant from two given points. Let the co-ordinates of the two points be

$$a,\ b,\ c;\ a',\ b',\ c';$$

and let x, y, z, be the co-ordinates of any point in the plane. The general expression for the distance of any point in the plane, from the point whose co-ordinates are a, b, c, will be

$$\sqrt{\left\{(x-a)^2+(y-b)^2+(z-c)^2\right\}};$$

and its distance from the point whose co-ordinates are a', b', c', will in like manner be

$$\sqrt{\left\{(x-a')^2+(y-b')^2+(z-c')^2\right\}}.$$

By putting the squares of these distances equal to one another, we get

$$-2ax-2by-2cz+a^2+b^2+c^2$$
$$=-2a'x-2b'y-2c'z+a'^2+b'^2+c'^2.$$

Let $A=2(a'-a)$, $B=2(b'-b)$, $C=2(c'-c)$, $-D=a'^2-a^2+b'^2-b^2+c'^2-c^2$, and we get

$$Ax+By+Cz+D=0$$

for the equation of a plane, from which it appears that the equation of a plane is the most general that can be formed by three indeterminate quantities of the first degree.

If we suppose one of the points to be at the origin of the co-ordinates, so that $a'=0$, $b'=0$, $c'=0$, the equation becomes

$$2(ax+by+cz)=a^2+b^2+c^2.$$

The point whose co-ordinates are a, b, c, is now in a line drawn from the origin perpendicular to the plane, and as far distant from it on one side as the origin is on the other; but if we now put the letters a, b, c, for co-ordinates of the point in which the perpendicular meets the plane, as the new values will be the halves of their former values, we have

$$ax+by+cz=a^2+b^2+c^2$$

for the equation of a plane.

Plate CCXXVII. Fig. 14.

47. We may introduce into the equation the angles which the perpendicular from the origin upon the plane makes with the axes, instead of a, b, c. Let AM (Fig. 14.) be the perpendicular, and M the point in which it meets the plane; then $MM'''=AP=a$, $MM''=AQ=b$, $MM'=AR=c$. Put α for the angle MAX, β for MAY, and γ for MAZ; and put d for MA, the distance of the plane from A. The angles MPA, MQA, MRA, being right angles, we have $AP=MA\times \text{Cos. }\alpha$ $AQ=MA\times \text{Cos. }\beta$, $AR=MA\times \text{Cos. }\gamma$, and $AM^2=AP^2+PM^2=AP^2+PM'^2+M'M^2$, that is in symbols $a=d\text{ Cos. }\alpha$, $b=d\text{ Cos. }\beta$, $c=d\text{ Cos. }\gamma$, $d^2=a^2+b^2+c^2$. Therefore, substituting in the equation, and dividing by d, it becomes

$$x\text{ Cos. }\alpha+y\text{ Cos. }\beta+z\text{ Cos. }\gamma=d.$$

By putting $d\text{ Cos. }\alpha$, $d\text{ Cos. }\beta$, $d\text{ Cos. }\gamma$, instead of a, b, c, in the equation $a^2+b^2+c^2=d^2$, we shall find that α, β, γ, are so related to one another, that

$$\text{Cos.}^2\,\alpha+\text{Cos.}^2\,\beta+\text{Cos.}^2\,\gamma=1.$$

48. Having given the equation of a plane, its position may be determined from these formulas. Let the equation be $Ax+By+Cz+D=0$; by putting it in this form, $\frac{A}{D}x+\frac{B}{D}y+\frac{C}{D}z+1=0$, and substituting A for $\frac{A}{D}$, B for $\frac{B}{D}$, and C for $\frac{C}{D}$, it will have this form, $Ax+By+Cz+1=0$. Compare this with the expression $-x\frac{\text{Cos. }\alpha}{d}-y\frac{\text{Cos. }\beta}{d}-z\frac{\text{Cos. }\gamma}{d}+1=0$, and we get $\text{Cos. }\alpha=-dA$, $\text{Cos. }\beta=-dB$, $\text{Cos. }\gamma=-dC$; from these equations we get $d^2(A^2+B^2+C^2)=\text{Cos.}^2\,\alpha+\text{Cos.}^2\,\beta+\text{Cos.}^2\,\gamma=1$, and $d=\frac{1}{\sqrt{(A^2+B^2+C^2)}}$. As we now know d, the distance of the plane from the origin of the co-ordinates, and α, β, γ, the angles which a perpendicular from the origin upon the plane makes with the axes, its position is determined.

The position of a plane may also be determined by other *data*, particularly by its intersections with the co-ordinate planes, which are called its *traces*; but our limits do not admit of our enlarging on this subject.

49. As the intersection of two planes is a straight line, if those have given positions, the line will have a determinate position. The position of a straight line in space may therefore be expressed analytically by the equations of any two planes which pass through the line. Accordingly, the *equations* of a straight line referred to three co-ordinate planes are,

$$Ax+By+Cz+1=0 \quad \ldots\ldots \quad (1.)$$
$$A'x+B'y+C'z+1=0 \quad \ldots\ldots \quad (2.)$$

the variable co-ordinates x, y, z, being supposed the same in both. These serve to characterize the nature of the line; for by giving any particular value to one of the co-ordinates, we can, by means of them, determine the other two, and thence the point of the line corresponding to the co-ordinates.

The above equations, however, are not the only ones by which the position of the line is determined, for we may eliminate each of the three quantities x, y, z, in its turn. Let this be done, and, for the sake of brevity, let

$$AB'-A'B=C^1,\quad CA'-C'A=B^1,\quad BC'-B'C=A^1,$$
$$A-A'=A^2,\quad B-B'=B^2,\quad C-C'=C^2,$$

and we shall get

$$C^1y-B^1z+A^2=0 \quad \ldots\ldots \quad (3.)$$
$$A^1z-C^1x+B^2=0 \quad \ldots\ldots \quad (4.)$$
$$B^1x-A^1y+C^2=0 \quad \ldots\ldots \quad (5.)$$

Any two of these equations (3.), (4.), (5.), may serve instead of equations (1.), (2.), and they implicitly contain the third.

The equation (3.), which expresses the relation the co-ordinates y, z, ought to have to one another for all the points of the proposed straight line, belongs also to a straight line traced on the plane YAZ, by letting fall perpendiculars from every point in the line in question on that plane, or to the intersection of the plane YAZ, and a plane passing through the line perpendicular to YAZ. The same is true also of equation (4.), in respect of the plane XAZ, so that by chusing the system of these two equations, the straight line proposed is considered as the intersection of two planes respectively perpendicular to the planes YAZ, XAZ. These planes, which are called the *projecting planes* of the straight line, because they meet the co-ordinate planes to which they are perpendicular in the projections of that line, are characterized by equations (3.) and (4.), each considered by itself.

In general, every equation containing two variable quantities comprehended in the same co-ordinate plane, ought to be regarded as belonging to a line traced through the bottoms of an infinite number of perpendiculars erected on that plane. If all the perpendiculars stand upon a single straight line, they will lie in a plane perpendicular to the co-ordinate plane. It must also be remarked, that when only one of the co-ordinates is determined, a plane is thereby indicated parallel to that to which the ordinate is perpendicular.

50. The equations of curve surfaces come next to be considered after that of a plane. Let us take the sphere as an example; supposing the co-ordinates of any point on its surface to be x, y, z, those of its centre to be a, b, c, and its radius $=d$, the expression we found in article 45, for the distance between two points in space gives us immediately

$$(x-a)^2+(y-b)^2+(z-c)^2=d^2;$$

or, $x^2+y^2+z^2+2ax+2by+2cz=d^2-a^2-b^2-c^2$, for the equation of the surface of a sphere.

If the centre of the sphere be at the origin of the co-ordinates, then a, b, c, are each $=0$, and the equation of the surface is simply $x^2+y^2+z^2=d^2$.

If a sphere be cut by a plane, it is known that the section will be a circle; now, as the co-ordinates of every point in the circumference of this circle must satisfy at once the equations of the sphere and plane, the position of a circle in space will be expressed by these two equations, viz.

$$Ax+By+Cz+D=0;$$
$$(x-a)^2+(y-b)^2+(z-c)^2-d^2=0.$$

51. Let RKS (Fig. 15.) be a line of any kind traced on the plane XAY, the nature of which is known by an equation between its co-ordinates AH and HK; and let a straight line KM move in space, so as to be always parallel to a line given by position, and at the same time pass through the line RS; by this motion, the line KM will generate in space the surface of a solid which may be called a *cylinder*, because of its analogy to the cylinder of the elements of geometry. Plate CCXXVII. Fig. 15.

To find the equation of this kind of surface, let $AP=x$, $PM''=y$, and $MM''=z$, be the co-ordinates of any point on it: Join KM″, and draw KN parallel to AX. Because the lines KM, MM″ are parallel to lines given by position, the plane KMM″ is parallel to a plane given by position, therefore KM″, its intersection with the plane XAY, is parallel to a line given by position; thus the angles MKM″, M″KN will each have a given magnitude; and as KM″M, KNM″ are right angles, the triangles KMM″, KNM″ are given in species: Hence KN, NM″ will each have a given ratio to M″K, and consequently to MM″. We have therefore $KN=mz$, $NM''=nz$, (where m and n express given numbers,) and as $AH=AP-KN$, and $HK=PM''-M''N$, we have $AH=x-mz$, and $HK=y-nz$: Therefore these values of AH and HK being substituted in the equation expressing the nature of the curve RKS, the result will be the equation of the surface of the cylinder.

Example. Let the curve RKS, the base of the cylinder, be a circle, whose centre is at A, the origin of the co-ordinates, and its radius $=a$. In this case $AH^2+HK^2=a^2$; therefore the equation of the surface of the cylinder is $(x-mz)^2+(y-nz)^2=a^2$, or

$$x^2+y^2+2mxz+2nyz+(m^2+n^2)z^2=a^2.$$

If the line KM be perpendicular to the plane XAY, then m and n are each $=0$, and the equation of the cylinder is $x^2+y^2=a^2$. In general, the equation of the surface of a cylinder perpendicular to one of the co-ordinate planes, is the same as that of its base or section with the plane.

To find the equation of the surface of a right cone whose vertex is at A, the origin of the co-ordinates, and the axis AR coincides with AZ, the axis of the ordinate Z. Let $AP=x$, $PM''=y$, and $M''M=z$, be the co-ordinates of any point M on the surface. Draw MR perpendicular to the axis of the cone, and join M″A. Because the cone is given, the ratio of RA to RM, that is, of MM″ to M″A is given; therefore $M''A=nz$, (n being a given quantity,) and since $AM''^2=AP^2+PM''^2$, we have for the equation of the cone

$$x^2+y^2=n^2z^2.$$

It appears that the surfaces of a sphere, a cylinder, and cone, have equations of the second degree, involving three indeterminate quantities. They therefore, as well as innumerable other surfaces, may be all included in one equation of this form

$$\begin{aligned}&Az^2+By^2+Cx^2+Dyz+Exz+Fxy\\&+Gz+Hy+Kx+L=0.\end{aligned}$$

As lines are arranged in classes according to the order of their equations, a like mode of classification may be applied to surfaces. Accordingly, on this principle, a plane is called a *surface of the first order*, and all surfaces expressed by the above equation are said to be of the *second order*.

The equation of a curve surface admits of transformations perfectly analogous to those we have explained in treating of curve lines: and they are effected in the same manner, viz. by changing the origin and the direction of the co-ordinates. Thus the general equation to a surface of the second order may be changed to

$$x^2+My^2+Nz^2+P=0,$$

where x, y, z still denote co-ordinates to perpendicular planes.

As a plane curve is produced by the common section of a plane, and a curve surface of any kind, a curve of *double curvature* may be produced by the section of two curve surfaces. If a sphere and right cylinder, for example, pass through each other, so that the centre of the sphere is in the circumference of the cylinder, the common section of their surfaces will be a curve of double curvature.

Let the centre of the sphere be at the origin of the co-ordinates, and its radius $=a$, also let the axis of the cylinder be in the plane XAZ, and put b for the radius of its base; then the equation of the two surfaces will be

$$x^2+y^2+z^2=a^2;\ 2bx-x^2=y^2.$$

And these two equations express the nature of the curve under consideration.

By eliminating y^2 from the first equation, we have the nature of the curve also expressed by the equations

$$2bx+z^2=a^2,\ 2bx-x^2=y^2.$$

Of these two equations, the second is the equation of the *projection* of the curve on the plane XAY, and the first is the equation of its projection on the plane XAZ; so that instead of considering the curve as the common section of a sphere and cylinder, we may regard it as the common section of two right cylinders, one having a circle for its base, on the plane of the co-ordinates x, y, viz. that which we have supposed in the hypothesis of the problem; and another having its base on the plane of the co-ordinates x, z. The equation of the surface of this last being $2bx+z^2=a^2$, it is easy to see that its base is a parabola.

Whatever has been said in a former article respecting the straight line, which is the common section of two planes, will apply equally to curves of double curvature, considered as the sections of two curve surfaces. Thus, let $z=F(x,y)$, $z=f(x,y)$, be the equations of the surfaces, where $F(x,y)$, and $f(x,y)$ denote any *functions* or *expressions* of calculation made up of x, y, and known quantities; the co-ordinates of the curve, which is their common section, must satisfy both these equations at once. Also, by elimination, we may deduce from these, three other equations, $z=\Phi(x)$, $z=\varphi(y)$, $y=\psi(x)$. These give respectively the projections of the curve of double curvature upon the planes of x, z, of y, z, and of x, y; each equation may be considered as belonging to a cylindric surface, the base of which is upon the plane of the two ordinates which enter into the equation. It follows from thence, that there are always five curve surfaces, any two of which may form, by their intersections, one and the same curve of double curvature, so that such a line may be formed in ten different ways.

The general Properties of Curve Lines, by Emerson.

(ξ)

CUSCO, or Cuzco, the most ancient city of Peru, in South America, the capital of a corregiomento in that viceroyalty, and the head of a bishopric. This city is situated in south latitude 13° 42′ 25″, and in west longitude 71° 4′ 15″, being distant from Lima 184 leagues, and 290 from La Plata. It stands on very uneven ground at the skirts of mountains, which are watered by the little river Guatanay, which, indeed, hardly exists except in the months of January, February, and March, its waters being through the other months of the year almost dried up, though the little that remains in it may still serve, in some degree, to irrigate the neighbouring plains. Most of the houses are of stone. They are well constructed, laid out in regular proportions, and covered with tiles of a bright red colour. The apartments are spacious and finely decorated; the mouldings of the doors are gilt, and the other ornaments and furniture are in a style corresponding to the elegance of the buildings, and the good taste for which the inhabitants are so generally noted. The population of this city is estimated by Alcedo at 26,000. It suffered, however, greatly by a pestilence in 1720, and of late years it has, very obviously, been in a declining state. Three fourths of the inhabitants are stated to be Indians, who are occupied chiefly in the manufacture of baize, cotton and leather, likewise of ordinary cloth, and a kind of linen used chiefly as clothing by the poor, saddles, floor-carpets, galloons of gold, silver, and silk, parchment, and other preparations from various skins. The natives, who are of an ingenious disposition, are also said to have a taste for painting, and to excel in the arts of embroidery and engraving. They are, in general, a very diligent, industrious people. The government of the city was, after the time of the conquests made by the Spaniards, vested in a secular cabildo, composed of two ordinary alcaldes, a royal ensign, an alguazil-mayor, a provincial alcalde, a depositor-general, twelve perpetual regidors, two alcaldes of the inquisition, and a regidor nominated annually with the title of judge of the natives, who was entrusted with the causes of the Indians: these having also a protector nominated every two years by the viceroy of Lima. This cabildo derived from the grant of the emperor Charles V. the same privileges which were enjoyed by the cabildo of Burgos. The principal acting magistrates were a corregidor and two alcaldes, who, according to the prevailing custom in all the cities of South America, were chosen from among the chief nobility. The noble Spanish families which had their residence in this city, were formerly very numerous; indeed it was very full of Spaniards of all descriptions while it continued to be in a prosperous and flourishing condition. In 1784, the office of corregidor was extinguished here, when his majesty established an intendant and governor vice-patron; and in 1787, the tribunal of royal audience, composed of a president, four oidors, and a fiscal. There are three colleges in Cusco. In one of these, distinguished by the name of San Antoin Abad, there is a seminary for the service of the cathedral, in which are taught Latin, the sciences, and divinity. Another of them, that of San Bernardo, which was founded by a Vizcayan for the sons of the conquerors, was formerly under the direction of the regulars of the society of Jesuits, and young men of fortune resorted thither to be instructed by these fathers. It is at present under an ecclesiastical rector. The branches of knowledge taught here were, as at the last mentioned seminary of education, grammar, philosophy, and theology. The third, called St Francis de Borja, belonged also to the Jesuits, and was appointed for the education of the sons of caziques or Indian princes, where they were initiated in their letters; and such of them, at least, as shewed any disposition towards that science, in the rudiments of music. By the two former of these colleges, all degrees are conferred below that of doctor; and they have been erected into universities. The courts of justice established in this city are, one for the revenue which consists of two judges, a court of inquisition, and one of the croisade, together with the other offices usually found in the large cities in this quarter of the world.

Cusco is an episcopal city, and its bishop is suffragan to the archbishop of Lima. The members of the cathedral chapter, besides the bishop, are five dignitaries, viz. the dean, archdeacon, chanter, rector, and treasurer; two canons by competition; a magistral and penitentiary; three canons by presentation; and two prebendaries. The cathedral is a large, rich, and handsome edifice, built entirely of stone. It is smaller than that of Lima, but is by some preferred to it in point of the architecture. The three curacies in the chapel of the Sagrario belonging to it, are served by the same number of priests, one of whom is for the Indians and negroes of the parish, and the other two for the Spaniards. There are, besides this, eight parishes in or belonging to the city; one of them, however, situated from it at the distance of one, and another of two leagues. The parishes within the city, are those of Neustra Senora de Belen, San Christoval, Santa Ana, San Blas, Santiago, and the Hospital. The two others are those of San Geronimo and San Sebastian. There are here likewise nine convents of different religious orders. One is that of the Dominicans, the principal walls of which were formerly those of the temple of the sun, and of which the high altar afterwards came to occupy the place where once there had been a golden image of that planet. The others are two belonging to the Franciscans; one to the Augustines, and one to the Fathers of Mercy, which are severally the heads of their respective orders in the province. One of the observers, another of the recoletans, and two colleges which belonged to the regulars of the extinguished company of the Jesuits, but of which the principal in the part lying towards the east is now destined for an armoury, and the other at the back of this, in which was the house for noviciates and students, is occupied as barracks for the troops; to all which may be added, the chapel of ease to the cathedral. The convent of San Juan de Dios, and that of the Bethlemites, which are both very large, are now used as hospitals for the sick; the latter being appropriated to the Indians, who are there treated with the greatest care and tenderness. Altogether there are four hospitals in the city. The first and most ancient of these is that of the Espiritu Santo. It is into it that Indians of both sexes are received. The patronage of it is vested in the secular cabildo; and it is governed by a junta of 33 persons, the president of whom, the alcalde, has the first vote, and after him the administrator or first brother. There are two chaplains belonging to this institution, and it has very ample revenues, one of the sources of which consisted in the duties paid upon all effects passing over the neighbouring bridge on the Apuremac. Till the year 1763, these droits had belonged to the royal exchequer, at which time, at the instance of the king's ensign, Don Gabriel de Ugarte, they were conceded by the king to the hospital, together with the right and property of the bridge, in redemption of some crown grants that had been left to the hospital by Don Rodrigo de Leon in Seville. Having thus become very rich, it has now no less than 250 beds. A jubilee has been granted to its chapel by the apostolical see, which is celebrated at the octave of Pentecost with much solemnity, and by an unusually great concourse of people; this having once, indeed, been the best observed jubilee of any in America. The hospital belonging to the religious order of San Juan de Dios is for men, and has 50 beds. The third hospital, called that of Nuestra Senora de la Almudena, is for all descriptions of individuals, and has also 50 beds; and the fourth, known by the name of San Andres, has 30 beds, which are appropriated to Spanish women. The nunneries of the city are those of St Clare, St Catherine, the barefooted Carmelites, and a Nazarene sisterhood. That of St Catherine is founded where the Incas kept the virgins dedicated to the sun. There are still other religious houses in this place, the principal of which are those of Nuestra Senora del Carmen of Santiago, and of San Blas.

The city of Cusco, as it is the most ancient, so, in point of extent, it is still the second in the viceroyalty of Peru, being only inferior to Lima; and so little inferior, that as the latter may be called the maritime capital of that viceroyalty, the former may be considered as its inland metropolis. Proudly situated amongst the surrounding Andes, and boasting of an origin that reaches back to a remote antiquity, it may justly lay claim to the dignity of a capital. Its north and west sides are surrounded by the mountain of the Fortress, and others, called by the general name Sanca; on the south it borders on a plain, in which there are several beautiful walks. The fortress which gives its name to the mountain, situated towards the north and the west of the city, is still to be traced in its ruins. These occur in the heights contiguous to the northern part of the city, and are the remains of the famous fort built by the Incas for their defence. Their design when they erected this edifice, appears to have been to inclose the whole mountain with a prodigious wall of such construction, as might render the ascent of it absolutely impracticable to an enemy, at the same time that it might be easily defended from within. This wall was entirely of freestone, and, like all the other works of the Incas, was strongly built, being particularly remarkable for its dimensions, and the magnitude of the stones of which it is composed, as well as the art with which they were combined. The stones, which form the principal part of the work, are indeed of such vast size, that it is difficult to conceive how they could have been brought thither from the quarries by the bare strength of men, unassisted by the use of machines. One of them, which is still lying on the ground, and which seems not to have been applied to the use intended, is called La Cansada, or the troublesome, in allusion probably to the labour with which its removal was effected. The interstices between those enormous masses were filled with smaller stones, which are so closely joined, that a very narrow inspection is necessary for perceiving that the whole is not a single block of stone. It may well appear surprising, how materials so vast and shapeless, and of so irregular a superficies as those which enter into this building, could be knit together, and laid one upon another with such nicety, independently of the use of mortar or any other combining substance; and yet more, without the knowledge, on the part of those by whom the building was erected, even of iron or steel, or the simplest of the mechanic powers. The outward wall of this fortress is still standing, but the internal works, which consist of apartments and two other walls, are for the most part in ruins. A subterranean passage, of singular construction, led from the fortress to the palace of the Incas. In these the walls were cut very crooked, admitting for a certain space only one person to pass at a time, and this sidewise, while shortly afterwards two might pass abreast. The egress was by a rock worked in the same narrow manner on the other side; the whole being upon a plan, which, by enabling a single person to defend himself with ease against a great number, seemed well calculated to afford security against any sudden assault. The whole of these ruins, together with the fragments of a pavement of stone built also by order of the Incas, and which led to the place where Lima now stands, are certainly no mean monuments of ancient art. The baths also, of which the one is of cold and the other of warm water, are not undeserving of attention.

Cusco is, in point of antiquity, coeval with the empire of the Incas. It was founded by the first Inca, Manco Capac (*i. e.* rich in virtue,) as the seat and capital of his empire. This prince is supposed to have reigned in the 12th or 13th century. Having peopled the city with the first Indians who voluntarily submitted to him, he divided it into two parts, which he called Hanam Cozco and Hurin Cozco, or High and Low Cusco, the former having been occupied by people whom the emperor had himself assembled, and the latter by those, who had been prevailed upon to leave their wandering manner of life by his consort Mama-Oello. Himself and this lady, who was also his sister, he declared, previously to their marriage, to be the children of the sun. The first mentioned division of the city is that which forms the northern, the other is the southern part of it. The houses were at first low and small, like cottages, the principal edifice being the temple of the sun, founded by this prince, and in which he appointed virgins of the royal blood to serve that divinity. As the empire, however, increased, the buildings assumed a new appearance, the streets being proportionably large, wide, and straight, so that the Spaniards, when they landed in this quarter, were astonished at the extent and splendour of the city, particularly at the magnificence of the temple of the sun, the grandeur of the palaces of the Inca, the strength and massiness of the fortress, and at the general appearance of a pomp and richness not unworthy of the seat of so vast an empire. It was in the month of October 1534, that Don Francisco Pizarro entered this city, and took possession of it in the name of Charles V. emperor and king of Spain. This was followed by a siege on the part of Inca Manco, who laid great part of it in ashes, but, without dislodging the Spaniards, Manco Capac was crowned here with the permission of Pizarro; but having been afterwards defeated by the Spaniards, he retired to the mountains, and is supposed to have died about the year 1553.

The commerce of Cusco, consists chiefly in the very large quantity of sugar made in the neighbouring jurisdictions, the inhabitants of which have many sugar plantations. Of these, the most noted is that of San Ignacia de Pachacaca, in the boundaries of the jurisdiction of Abancay, and which formerly belonged to the regulars of the Jesuits. The mint, which was formerly established here, has for some years been abolished.

In a magnificent chapel of the cathedral, there is venerated a miraculous crucifix, which was presented by the emperor Charles V. and which is called De los Temblores, from its having been invoked here as a patron, in the tremendous earthquake which took place in the year 1590. There is also an image of Nuestra Senora de Belen, known by the name of La Lenda, (the beautiful,) the gift of the same royal hand.

The diocese comprehends 14 jurisdictions. The first of these is that which is called the jurisdiction of Cusco, and which extends to the distance of two leagues. In this district, the temperature of the air is various. In some parts, indeed, the cold is said to be intense, but generally both the heat and cold are very supportable. The very coldest parts produce good pasture for all sorts of cattle, while the vallies afford plenty of grain and fruits. In the intendancy of Cusco, as this district is now called, with its dependency of Carahuasi, the only mines which, in the Mercurio Peruano, are mentioned to have been found, are those of silver, nineteen in number, and which have been successfully wrought. The other jurisdictions of the diocese of Cusco, are those of Quispicanchi, of Avancay, of Paucartambo, of Colcaylares, of Chilques and Masques, of Colobambo, of Cances or Canches, or Tinta, of Aymaraez, of Chumbi-Vilcas, of Lampa, of Carabaya, of Asangaro and Asilo, and of Apolo-Bambu. See Ulloa's *Voyage to and History of South America*, vol. ii. &c. and Thomson's *Alcedo*, vol. i. (K)

CUSCUTA, a genus of plants of the class Tetrandria, and order Digynia. See BOTANY, p. 127.

CUSERUND, or CASEREUND, is a town of Persia in the province of Mekran. It is situated in a fertile valley about twenty-one miles broad, and is divided into two parts by a large river, which throws itself into the Indian Ocean near Gwuttar. The cultivated part of the surrounding territory is about eight miles in circumference, and has an abundant supply of water from twenty-five large springs on the north side of the valley. Wheat, rice, and dates are produced in the greatest plenty; and the county is under the dominion of an independent chief, who draws from it an annual revenue of nearly one thousand rupees. The town is defended by a mud fort, and contains 500 souls. East longitude 60° 43′, and North latitude 26° 20′. See Macdonald Kinneir's *Geographical Memoir of the Persian Empire*, p. 206. (*w*)

CUSSONIA, a genus of plants of the class Pentandria, and order Digynia. See BOTANY, p. 162.

CUSTOMS. See the statistical account of ENGLAND, in which this subject will be discussed.

CUSTRIN, or KUSTRIN, a strong and well built fortified town of Prussia, in the Newmark of Brandenburg. It is situated in the middle of a morass, at the confluence of the Warther and the Oder. The road which leads to Custrin from the circle of Lebro, is a fortified dyke or causeway about four miles long, and having no fewer than 36 bridges in that space. The road towards the Newmark is another causeway, and has only seven bridges.

Custrin is strongly defended both by art and nature. There are only about 200 houses within the walls, but the suburbs are more extensive and more handsome than the town itself. The principal public buildings are four churches, three magazines, and two hospitals. The magazines and arsenals are particularly worthy of notice. The inhabitants are much addicted to agricultural pursuits; but the sandy and marshy nature of the soil, prevent them from carrying on any trade in the productions of their territory. They obtain, however, great abundance of fish from the lakes and marshes; and after supplying their own wants, they export every year great quantities of salted fish. In the reign of Frederick II. several of the marshes were drained, and converted into rich meadows.

This town was burned by the Russians in 1739, although it was not taken. In 1758, the Russians reduced it to a heap of ruins, but they were still unable to take the town. In 1806, it surrendered by capitulation to Marshal Davoust, and the garrison, consisting of 4000 men, were made prisoners of war. It is at present (1814) besieged by the allies, and must speedily fall into their hands. (π)

CUTANEOUS DISEASES. See MEDICINE.

CUTCH GUNDAVA, a district of Persia, which will be described under the head of MEKRAN, the province in which it is situated.

CUTCH, GULF OF, is an extensive gulf of the Indian Sea, formed by the coast of Cutch to the north, and the coast of Guzzerat to the south. It extends a considerable distance to the eastward, and at the head of it is a low barren track, which the sea inundates during the monsoon. It is said to communicate with the river Ram in the Gulf of Cambay, and thus to form the province of Guzzerat into an island. This gulf contains numerous shoals, and is very imperfectly known. The capital of Cutch is Bhooj, which is about 25 miles to the north-west of Muddi. Muddi, or Musher Maundvee, or Mandivee, is the great port of Cutch, and is situated in east longitude 69° 25′, and north latitude 22° 50′. It is a large town, and well fortified, but the houses are built merely of mats and bamboos. A considerable trade is carried on between Muddi and Bombay, and also to the Persian Gulf. Cotton is the principal article of produce, but it is inferior to that which grows in Surat and the Gulf of Cambay. The following is a list of the exports and imports in 1805, from the coast of Scindy and Cutch to the British settlements in India, as given by Milburn in his Oriental Commerce.

Exports in 1805.	Sicca Rupees.
Cotton	1,585,520
Ghee	440,709
Grain	267,644
Oil	45,477
Piece goods	54,798
Seeds	59,853
Kismisses,	29,791
Indigo	12,476
Sharks' fins	8,609
Shawls	11,356
Drugs	32,655
Sundries	97,303
Total amount of exports to India in sicca rupees	2,646,191

Imports in 1805.	Sicca Rupees.
Piece goods	117,917
Pepper	119,723
Raw silk	129,395
Sugar and jaggery,	545,999
Betel nut	38,218
Copper	80,037
Cochineal	18,231
Cocoa nuts	48,355
Coir	30,099
Cardamoms	15,098
Carry forward	1,143,072

Cutting ‖ Cyanometer.

	Sicca Rupees.
Brought forward	1,143,072
Drugs	47,431
Grain	54,143
Iron	24,302
Steel	23,518
Japan wood	11,554
Tutenague	16,636
Tin	19,365
Spices	15,914
Sundries	81,640
Treasure	250,370
Total amount of imports from India in sicca rupees	1,687,945

CYANELLA, a genus of plants of the class Hexandria, and order Monogynia. See Botany, p. 189

CYANOMETER, from κυανος, *blue*, and μετρον, *a measure*, is the name of an instrument, or rather of a method invented by M. de Saussure for estimating the intensity of the blue colour of the sky. A circular band, or zone, made of thick paper or pasteboard, is divided into fifty-one parts, each of which is painted with a different shade of blue, varying by gradual tints from the deepest blue, formed by a mixture of black, to the lightest, which is formed by a mixture of white. This coloured zone is then held in the hand of the observer, who notices the particular tint which corresponds to the colour of the sky. The number of this tint, reckoned from the greatest, will mark the intensity of the blue colour of the sky at the time of observation.

Saussure's cyanometer.

This instrument has been used not only by Saussure, but also by the celebrated traveller Baron Humboldt, and by M. Depons, to whom we are indebted for the three following results:

General intensity of the blue colour of the sky in Europe	14°
Do. do. at Caraccas	18
Do. do. at Cumana	24

Various opinions have been entertained respecting the cause of the blue colour of the sky. Fromondus attributed it to a mixture of light with the black space beyond our atmosphere. Faber supposes it to arise from the reflexion of the light by particles floating in the air. Funccius, who wrote a treatise on the subject, asserted, that the blue colour was a mixture of much shade and little light. Otto Guericke maintained, that white and black, when mixed together, will form a blue like that of the sky; and the same vague notion received the support even of Wolfius and Muschenbroek. Dr Eberhard imagines, that the air has a proper colour of its own, in consequence of *refracting the blue rays more than others*. It was reserved, however, for M. Bouguer to assign the most probable reason for the blueness of the sky. The red rays being less refrangible than the blue ones, and less apt to be obstructed or thrown back in their progress through an imperfectly transparent medium, will consequently force their way through the atmosphere, while the blue rays, having less power to overcome the resistance to which they are exposed, will be reflected, and, of course, give the sky a blue colour.

This opinion, however, though rendered probable by many considerations, still required the evidence of demonstration, which we think it has lately received. "We have already seen," says Dr Brewster in his *Treatise on New Philosophical Instruments*, p. 349, "that the singular decomposition of light produced by the intervention of a plate of mica, is exhibited only where the transmitted rays have been previously polarised. This alternation of the prismatic colours, therefore, may be assumed as a decisive test, that the light by which they are formed has received, either wholly or partly, the character of polarisation; and by thus distinguishing *reflected* from *direct* light, it enables us to account for several interesting phenomena which have been only hypothetically explained.

Cyanometer.

"When we examine the light of the clouds by a prism of Iceland spar, and interpose a plate of mica, the alternation of the prismatic colours is distinctly visible, although none of the two images formed by the spar vanishes in every quadrant. It follows, therefore, that the light of the clouds has been partly polarised by reflexion

"When the *blue light* of the sky is examined in a similar manner, the play of the prismatic colours is still more brilliant than in the preceding experiment, and one of the images suffers a visible diminution of brightness at every quarter of a revolution. Hence we may conclude, *that the blue light of the sky has experienced a partial polarisation, and that it is reflected from the atmosphere with which the earth is surrounded*."

M. de Saussure found, that the intensity of the blue colour increased with the elevation above the level of the sea; and it has also been observed, that the intensity of colour is diminished as the quantity of aqueous vapour is increased. Hence the measures taken with the cyanometer are supposed to indicate the quantity of water actually dissolved in the air.

Another cyanometer, obviously more accurate than that of Saussure's, and more deserving of the name of an instrument, has been constructed by the writer of this article. It consists of two plates of glass, about twelve inches long, joined together at one end, so that their surfaces may form an angle of from 12° to 20°. These plates form two of the sides of a prismatic vessel, which is filled with a blue fluid, having such an intensity, that the blue colour near the top of the vessel, where the distance of the plates is small, is less than the minimum blue of the sky, while the intensity of the blue colour at the bottom of the vessel exceeds the deepest tinge which is ever found in the atmosphere. Between these two extremes there is a regular gradation of tints, and by a proper adjustment of the length of the plates to the angle which they form, and to the intensity of the blue fluid, a scale of convenient magnitude may be obtained. In using this instrument, a white circular spot may be made to move upon a black ground, so as to be seen through the fluid in any part of its progress from the one end to the other of the prismatic vessel. The light which illuminates the white circular space, may be either common light, or, by making the white spot move in contact with one of the glass plates, the light will first pass through the fluid to the white spot, and then be reflected back again to the eye. In this last case, the intensity of the blue colour will be very great.

New cyanometer.

By using four, six, eight, ten, or twelve glass plates, a prismatic vessel with several sides may be constructed; and by making the distance of each pair of plates different, and altering the angle which they form, a scale of any magnitude may readily be obtained. (*o*)

CYCLE. See CHRONOLOGY.

CYCLE, in Music, is a term used by Dr Robert Smith, in his *Harmonics*, for certain determinate periods, or series of pulses or vibrations, excited in the air by the consonance or sounding together of two musical sounds. These cycles he distinguishes into four kinds, (p. 56. 2d edit.) viz. 1st, *Simple* cycles, generated when the least or lowest terms of the ratios, expressing intervals, differ only by unity, as $\frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \frac{4}{5}$, &c. 2d, *Complex* cycles, when these terms differ by more than 1, as $\frac{1}{3}, \frac{2}{5}, \frac{5}{9}, \frac{27}{32}, \frac{8}{15}$, &c. 3d, *Short* cycles, formed by the pulses of perfect consonances, or those whose ratios are truly expressible, without using very large numbers, as $\frac{1}{2}, \frac{3}{5}, \frac{8}{9}, \frac{80}{81}$, &c. And, 4th, *Long* cycles, of the pulses of imperfect unisons, or other consonances, which are not expressible but by very high or large numbers, as $\frac{292\,2977, \&c.}{292\,3003, \&c.}$ to 49 places of figures, which answers to *m*, the least known interval. See our Table in Plate XXX. Vol. II.

The complex long cycles of imperfect unisons, may be ever so long, infinite, or impossible, and yet the indeterminate periods of their pulses, which excite the determinate sensation of these imperfect unisons, will have each a finite or determinate *limit*, to which they approach, p 101; and hence Dr Smith imagines, that the identity of the tone of imperfect unisons, when held out or sounded together sufficiently long upon an organ, may be accounted for, p. 102. And hence the difficulty, or uncertainty, in transferring unisons from a monochord to a piano-forte, or from a standard pipe to an organ, with the requisite accuracy. (*g*)

CYCLOID. See EPICYCLOID, MECHANICS, and PENDULUM.

CYDER is the name of a fermented liquor, which is made in England in great quantities from the expressed juice of apples. After the apples are gathered from the trees, they are ground into what is called pommage, either by means of a common pressing stone, with a circular trough, or by a cyder mill, which is either driven by the hand, or by horse-power. When the pulp is thus reduced to a great degree of fineness, it is conveyed to the cyder press, where it is formed by pressure into a kind of cake, which is called the cheese. This is effected by placing clean sweet straw, or hair-cloths, between the layers of pommage, till there is a pile of ten or twelve layers. This pile is then subjected to different degrees of pressure in succession, till all the *must*, or *juice*, is squeezed from the pommage. This juice, after being strained in a coarse hair sieve, is then put either into open vats or close casks, and the pressed pulp is either thrown away, or made to yield a weak liquor called *washings*.

After the liquor has undergone the proper fermentation in these close vessels, which may be best effected in a temperature of from 40° to 50° of Fahrenheit, and which may be known by its appearing tolerably clear, and having a vinous sharpness upon the tongue, any farther fermentation must be stopped by racking off the pure part into open vessels, exposed for a day or two in a cool situation. After this, the liquor must again be put into casks, and kept in a cool place during the winter. The proper time for racking may always be known by the brightness of the liquor, the discharge of the fixed air, and the appearance of a thick crust formed of fragments of the reduced pulp. Mr Knight is of opinion, that the liquor should always be racked off anew, as often as a hissing noise is heard.

When a favourable vinous fermentation has been obtained, nothing more is required than to fill up the vessels every two or three weeks, to supply the waste by fermentation. On the beginning of March, the liquor will be bright and pure, and fit for final racking, which should be done in fair weather. When the bottles are filled, they should be set by uncorked till the morning, when the corks must be driven in tightly, secured by wire or twine and melted rosin, or any similar substance. Such of our readers as wish for more copious details respecting the process of cyder-making, will find abundance of information in the agricultural surveys of the English counties, where cyder is made in great quantities. See particularly Vancouver's *Survey of Devonshire*; Rudge's *Agricultural Survey of Gloucestershire*; and Duncomb's *General View of the Agriculture of the County of Hereford*. (*j*)

CYPRUS, a large island in the Levant, and situated in north latitude 35°, and east longitude 33°. It is about

Cyprus.

Ancient history of Cyprus.

70 leagues in length from east to west, and about 30 in its greatest breadth from north to south; and lies nearly at an equal distance from Caramania on the north, and from Syria on the east. It was even supposed by the ancients to have once formed a part of that country, and to have been detached from it at an early period of the world, during some violent convulsions of nature, as Sicily from Italy. According to some authors, this island received its name from the abundance and beauty of the copper which it contains in its bosom, and which being found formerly in metallic masses, and being less difficult to melt than iron, was employed by the ancients for fabricating their implements of agriculture, and their weapons of war. Others again maintain, that the word Cyprus is borrowed from a shrub, called by the Greeks Kupros, and by the Hebrews Kopher. It is the *henne* or *hanna* of the Arabs, the *kanna* of the Turks, and the *Lawsonia inermis* of Linnæus. From this tall shrub, which abounded in the island, its ancient inhabitants made an oil of an exquisitely delicate flavour and taste, which was an article of great importance in their commerce, and is still in great repute among the eastern nations. Besides this, however, it had a variety of other names, a long enumeration of which is given by Pliny, (*Hist. Nat.* lib. v. cap. 31.) Among these, *Macaria*, or the Fortunate Island, appears to have been the most appropriate, as there were few places in the world that could compare with it, in fertility of soil, in mildness of climate, in the beauty of its plains, and in the richness of its productions.

Our readers need not be informed, that this island was in a peculiar manner consecrated to Venus. This goddess, the mother of the Graces, the Loves, and the Pleasures, was said to have sprung from the froth of the sea near this island, to which she was wafted by the Zephyrs, and received on the sea-shore by the Seasons, the daughters of Jupiter and Themis. She was called by the poets, not only the Cyprian but the Paphian queen, because she was worshipped by the whole island, but in particular by the inhabitants of Paphos, one of its most populous cities on its western coast, where an hundred altars daily smoked with male animals offered in sacrifice, and perfumed with the richest odours of Arabian frankincense.

Eratosthenes affirms, that the Phœnicians first discovered this island about 1045 years B.C. But to reconcile this account with what Josephus relates, we must admit, that it was then inhabited by the descendants of Cittim, the grandson of Japhet, who first peopled the island, and laid the foundation of Citium, the oldest of its cities. The aborigines, however, seem to have lived entirely upon the spontaneous productions of the earth, and by hunting, and to have made no advances towards civilization. The Phœnicians no sooner landed, than they began to level the immense forests which covered the whole country; to employ the wood in melting the copper which they knew how to manufacture, and to cultivate the grounds which they had cleared. The government which they established was monarchical, and the island was divided into four provinces, or rather dynasties; for each seems to have been independent, and to have had its own king. Salaminia, on the east; Amathusa, on the south; Papphia, on the west; and Lapytha, on the north. The Phœnicians not only introduced among them the arts, but also the sciences which they possessed; and though, in process of time, colonies from Greece and Ethiopia settled there, and no doubt blended their original manners and customs with the manners and customs which prevailed in their new habitations, yet still the strong features of their civil and religious institutions evidently prove that they were derived from the same Phœnician source.

Cyprus.

Ancient history of Cyprus.

The annals of this country are at first obscure and uninteresting. Cinyras, the son of Paphos, and grandson of Pygmalion, is the first who is said to have erected his throne at Paphos, and to have transmitted to his son Adonis, the sceptre of the Paphian state. The names of his other descendants are unknown; and from them our attention is drawn to Teucer, who, after the fall of Troy, laid the foundation of Salamis, and assumed the sovereignty of a new dynasty, which he called Salaminia, and which soon surpassed every other in the island. His immediate descendants left not the wreck of a name for many generations. About 525 years B. C. Nicocreon is mentioned only as the father of Enelthon, who succeeded him. Enelthon is said to have been the first who yielded the independence of his country to the Egyptians, and afterwards to the Persians under Cambyses. After this, Siromus, Chersis, and Gorgus, successively wielded the sceptre of Salamis, as tributaries of Persia. Onesilus, the brother of the latter, indignant at the disgrace which his country endured from this subjection, conjured Gorgus to throw off the yoke of Persia, and vindicate the dignity of his throne; and enraged, because the prudence or cowardice of his brother shrunk from the danger, he drew a number of his countrymen to enter into a conspiracy; drove his brother from his kingdom, who fled to Persia; roused the other states of Cyprus to unite against the common enemy; persuaded the Ionians to join him with their fleet; and, at the head of the confederates, met the powers of Persia on the plains of Salamis. The conduct of Onesilus on that bloody day, though it could not vindicate his usurpation, proved that he was worthy of a better cause. With his own hand, he slew the leader of the Persians; led his countrymen, with equal skill and courage, to brave and to sustain the superior power that opposed them; and when the revolt of Stesenor, King of Curium, and part of his own forces, snatched from his hand a victory which his valour had almost purchased, he fell on the field amidst heaps of his enemies. His brother again mounted the throne, and was succeeded by his son Nicrocatus; he by his brother Timarchus; and he by Evagoras I. the son of Nicocrates. In his reign, the Athenians formed the glorious design of confining the Persians to their own dominions; invited all the states subjected to their power to vindicate their independence; and sent Cimon, with a fleet of 200 vessels, to drive them from Cyprus. Cimon, worthy of the work assigned him, not only expelled the Persians from many of the Cyprian cities, but attacked Artabazus, who commanded their fleet of 300 sail; took 100 of his ships, destroyed many more, and pursued the rest to the shores of Phœnicia. On his return he landed his forces in Cilicia, defeated Megabazus, at the head of 300,000 Persians; and again embarking his hardy veterans, set sail for Cyprus, and landing there, laid siege to Citium. Evagoras, however, dead to his own glory and to the liberty of his country, joined the Persians; and endeavouring to raise the siege, was defeated with a great slaughter. Artaxerxes, however, tired of a destructive war, renounced his claims upon Greece and Cyprus; and thus, the kings of the latter, received that freedom of which they had proved themselves unworthy. A short time after this, Evagoras was driven from the throne by his nephew Protagoras; and under him and his son Nicocreon II. famous for his cruelty, the Cyprians enjoyed independence, till Artaxerxes Mnemon again subjected them to the Persian yoke. Niocles, who succeeded Nicocreon, was expelled from his country by one Abdymon, a stranger, who had been kindly received and entertained by the monarch whose throne he usurped. The son of Niocles, Evagoras II. endowed with every quality of body or of mind that could form him for sovereignty, rose up to avenge the wrongs of his father, and to vindicate to himself the crown of his ancestors. But whilst he was preparing for the attempt, one of the principal citizens struck the blow, and seized the sceptre of Abdymon, whom he had murdered. But the son of Niocles, returning from exile, roused the Cyprians, who flocked to his standard; delivered his countrymen from the usurper, under whose cruelty they groaned, and expelled the Persians who endeavoured to support him. Flushed with his success, he attempted to reduce the whole island under his subjection, and almost accomplished his ambitious design. But the Amathusians, Solians, and Citians, who only braved his arms, implored the assistance of the Persians; and the Persians, remembering former injuries, promised their aid, made peace with the Greeks, and collected their powers to expel him from his country. Evagoras saw the storm that his ambition had raised, and prepared to arrest it in its course. The Athenians, whom, after their defeat at Ægospotamos, he had protected, the Egyptians, Lybians, Arabians, Tyrians, all who were at war with Persia, he invited to his assistance; and when the fleet of the enemy threatened his shores, and poured upon the island 300,000 men, with Tiribazus at their head, to sweep the interior country, he dared to meet the overwhelming torrent, and entirely dissipated its enormous force. But when he attacked them by sea, he lost the battle, but not his fame. After performing prodigies of valour, he found himself not only blocked up and besieged in Salamis, but obliged to yield up, at the command of Persia, the conquests which he had made, though he bravely preserved the independence of his paternal dominions. Being soon after murdered by Thrasidæus, one of his eunuchs, his son Niocles II. who succeeded, performed nothing to arrest our attention: but his friendship for Isocrates, who lived during his reign, and experienced his bounty, will preserve his name from oblivion. At his death, his son Evagoras III. ascended the throne, but the government was soon wrested from him by his uncle Protagoras, who seized the sceptre, and joining the Egyptians and Phœnicians, attempted to throw off the Persian yoke. In consequence of this, Ochus espoused the cause of the exiled monarch, joined his Persians with Phocion, who commanded the Greek mercenaries, made a descent upon the island, and besieged Salamis. But the kings of Cyprus, nine in number at that time, united under Protagoras to vindicate their freedom; and the king of Persia, meeting with greater resistance than he expected, and bent upon the reduction of Egypt, granted their demands, and left Protagoras in possession of the throne. From this period, the kings of Cyprus seem to have slumbered in indolence, under the shade of Persia, till Alexander reduced the island to subjection. At his death, it composed part of the kingdom of Antigonus; but whilst that prince was engaged in war with Cassander, Ptolemy, the son of Lagus, made a descent upon the island, and forced its kings to yield to his power. At this time, Niocles, who had the chief power amongst those who retained some shadow of royalty in the island, entered into an agreement to assist Antigonus to recover it, but being discovered, he slew himself to avoid the punishment which Ptolemy had prepared for him; and his wife, Axiothea, after slaying all her daughters, imitated the example of her husband, lest she should fall into the hands of the enemy, and thus extinguished the royal race of Teucer. To wrest the island from Ptolemy, Demetrius, the son of Antigonus, at the command of his father, collected an army in Cilicia, landed upon the shores of Cyprus, stormed some of the inferior cities, advanced to form the siege of Salamis; dissipated, in a fierce battle, the forces of Menelaus, the brother of Ptolemy, who endeavoured to stop his progress; pursued the vanquished to the gates of Salamis, and invested the city. But hearing that Ptolemy, to support his brother, sailed from Egypt with 140 ships of war, 200 transports, and ten thousand soldiers, he took the command of his fleet, consisting of 108 ships; gave battle to the enemy, who had reached the coast; and after a dreadful engagement, which was long doubtful, he gained a complete victory. Upon this, the whole island submitted to the conqueror, and his father, Antigonus, assumed the title of king. At his death, the title and authority descended to Demetrius; but at the end of eleven years, whilst he was engaged in a war with the Athenians and Lacedemonians, Ptolemy landed upon the island, and took possession of the capital, before Demetrius could be informed of his design. After it had remained for some time subject to the kings of Egypt, it seems to have been wrested from them by Syria; but if this was really the case, the Egyptians soon recovered it, and kept the possession till the death of Ptolemy Lathurus. At his death, his two sons divided his dominions, and the kingdom of Cyprus fell to Ptolemy. This prince, refusing to advance money to purchase the liberty of Clodius, a Roman nobleman who had been taken by pirates, became the object of his hatred and revenge. After having acquired his liberty, Clodius was elected tribune of the people; and, prompted by resentment, he procured a decree, which the senate did not oppose, that Ptolemy, by his vices, was unworthy of his throne, and that the kingdom of Cyprus belonged to the Romans. The pretence under which the Romans veiled their injustice, was, that Alexander, late King of Egypt, had, at his death, bequeathed his dominions, including Cyprus, to the Romans. This donation, though mentioned at the time, had passed unnoticed on account of its injustice, but was now revived to gratify the vengeance of an individual, and the rapacity of the republic. Cato was commissioned to execute this disgraceful decree; and it deserves to be mentioned, that this person, who has been extolled as the most virtuous of the Romans, performed, without remorse, the iniquitous part which was assigned to him; took possession of the island without resistance; and after driving a king, who had been called the friend and ally of the Roman people, to lay violent hands upon himself, seized upon his treasures, amounting to 7000 talents, or about £1,356,250 sterling, and conveyed them to Rome. Thus, then, in the year 58 B. C. the sovereignty of Cyprus was for ever extinguished, and the island became a part of the Roman empire. The history of Cyprus, since that period, is naturally involv-

Cyprus.

ed in that of the different powers to which it became subject. It was conquered by the Saracens from the Europeans of the west; but fell under the dominion of the Venetians during the Crusades. The Venetians were in their turn driven from it by Sultan Selim in 1570, since which time it has constituted a part of the Ottoman Empire.

General description of the coast.

At a distance, Cyprus appears mountainous, rising in height towards the east; but upon approaching the shore, villages and some fertile plains are seen skirting the foot of the hills, some of which are craggy, and of considerable height. It is rounded on the south-west, and gradually narrows, until it draws out into a long point, terminated by Cape St Andrew on the east. On coasting along the southern shore from this point, the town of Famagusta appears, lying at the bottom of a large gulf of the same name. It is supposed to have been built upon the ruins of the ancient Arsinoe, and is defended by some fortifications which had been erected by the Genoese and Venetians, but which are now falling fast into decay. Its harbour is safe but small, and half choked up with sand. Proceeding west, we find the gulf of Larnica, which affords an excellent road-stead for vessels of any size, and which is the most frequented in the island. The town, (the ancient Citium), from which it takes its name, stands at some distance from the sea. It is the residence of the European consul and merchants, and is still a place of considerable trade.

Famagusta.

The situation is rather unhealthy, being surrounded by arid and barren plains, and exposed to a suffocating heat. These plains, however, were formerly covered with forests of olive trees; and, in the neighbourhood are still to be seen immense cisterns, which had been erected for the purpose of preserving the oil which they yielded. With the exception of the gardens adjoining the town, scarcely a vestige of cultivation remains. These gardens, however, are very beautiful. Every house almost has its garden, which is enclosed with lofty walls, and contains every kind of delicious fruits and flowers. About a mile south, on the coast, is the town of Salines, which takes its name from a cluster of salt lakes in its vicinity. It is the port of Larnica, where the merchants have their warehouses, and where almost all commercial transactions are carried on. The southern promontory of the island is a small peninsula, joined to the continent by a very narrow tongue of land. It was formerly named the promontory of Agrotiri, now Cape de Gatti, from the multitudes of cats which were kept by the monks who, in the 4th century, had permission to settle here, and also on Mount Olympus, upon condition of their keeping a great number of these animals for destroying the snakes which had almost entirely overrun the island. On doubling Cape de Gatti, the coast bends to the north-west, and a little more than half-way between this cape and cape St Epiphanes, the north-west part of the island, stands the small town of Baffa, (the ancient Paphos), which consists of the ruins of its former magnificence, a few mean Greek churches, some paltry houses, and a wretched fort. On the north side of the island, Cerina (formerly Ceraunia) is the only place worth mentioning, and its ruins also bear ample testimony to its past grandeur.

Salines.

Baffa.

Description of the interior.

The interior of the island is divided by a chain of mountains which runs lengthwise from west to east. The most remarkable of these is Little Olympus, so called to distinguish it from another mountain of the same name in Natolia; and also a still more famous one in Macedonia. Some of them exhibit curious forms, standing insulated, and having flat tops, resembling what are usually called table-mountains. Near the centre of the island, and in the middle of a vast and beautiful plain, stands Nicotia, the capital of Cyprus. The situation is agreeable. The soil around it is excellent, and is watered with abundant streams; and the town is surrounded by fine gardens. It is the residence of the governor, who now occupies one of the palaces of its ancient sovereigns. The palaces are remarkable for the beauty of their architecture, but are abandoned by their Turkish masters to the destructive hand of time. The fortifications of this town are still nearly entire, and although neglected, yet they surpass in beauty and magnificence those of almost every other city. The moat is half a mile wide, but is now dry, or at best but an unwholesome swamp; and a few pieces of artillery are now its only defence. The church of St Sophia, in this place, is a very superb and beautiful edifice. It is built in the Gothic style, and is said to have been erected by the Emperor Justinian, when he raised the church of the same name at Constantinople. It has three large naves; but the choir and the altars were destroyed when the city was taken by the Turks. Here the Christian kings of Cyprus were formerly crowned; and it still contains the tombs of the Lusignans, and of several ancient Cypriots and noble Venetians. It is now converted into a mosque. There is no other place in Cyprus worth our notice; and this island, which was formerly divided into nine kingdoms, and was so famous for its superb edifices, its elegant temples, and its riches, can now boast of nothing but its ruins, which will tell to distant times the greatness from which it has fallen.

Nicotia.

Climate.

The chain of mountains which intersects Cyprus, produces also a very material difference of temperature in the two divisions of the island. In the northern region, the heats of summer are tempered by the refreshing winds which blow from the high mountains of Caramania. These produce piercing colds during winter, and even preserve the snow on some of the highest spots during the greater part of the year. But on the south, the north winds are impeded by the mountain barrier; and the heats are increased by the reflection from the shelving rocks, which form the declivities of the hills, and from a soil so white that the glare is often sufficient to cause temporary blindness. The southern coast is also liable to hot winds from almost every point of the compass. These come from the parched deserts of Curdistan on the north-east, from the sands of Palmyra on the east, from the Great Desert of Arabia on the south-east, and on the south and south-west from Egypt and Lybia. During a squall from the north-east, Dr Clarke endeavoured to ascertain the temperature. "We found it so scorching," says he, "that the skin instantly peeled from our lips; a tendency to sneeze was excited, accompanied with great pain in the eyes, and chopping of the hands and face; and the mercury exposed to its full current rose 6° of Fahrenheit in two minutes, from eighty to eighty-six." The heats are sometimes so excessive, that persons going out without an umbrella are liable to suffer from a *coup-de-soleil*, or sun-stroke, a malady by no means uncommon in this island; and the inhabitants, especially of the lower class, in order to guard against it, wrap up their heads in a large turban, over which, in their journies, they place a thick shawl many times folded. They seldom, however, venture out of their houses du-

Cyprus.

ring mid-day; and all journies, even those of caravans, are performed in the night. Rains are also very rare in the summer season; and long droughts banish vegetation, and attract numberless columns of grasshoppers, which destroy the plants and fruits. Rivers are very scarce, and, indeed, the most of them are quite dry during the summer months. Sudden rain swells them into torrents; and they are supplied in the spring by the melting of the snow on the mountains.

Soil and agriculture.

The soil throughout the island is in general excellent. In some places it is a white marly clay, said to be exceedingly rich, and requires only the hand of cultivation, and the fostering care of a liberal policy, to make it yield the most abundant and luxuriant harvests. But its fertile plains are condemned to barren nakedness, by the tyranny and exactions of its government. The Greeks are so oppressed by their Turkish masters, that they dare not even cultivate the land, as the produce would instantly be taken from them; and their whole object is to collect together as much grain in the course of the year, as is barely sufficient to pay their tax to the governor, the omission of which is often punished by torture or by death. Wheat and barley were formerly principal articles of exportation from this island; but now scarcely sufficient is raised for the subsistence of the inhabitants. Its agricultural riches, however, though much neglected, and greatly reduced in quantity, are yet far from being inconsiderable.

Olive trees.

Olive trees were formerly very numerous in Cyprus, and the great quantities of oil which they produced, is attested by the immense reservoirs which still subsist in the environs of Larnica. It once formed a very important branch of commerce, but all that is now furnished is consumed in the island. The culture of the mulberry tree is also much abandoned, though still small woods of them are found in several places, and afford nourishment to a great number of silk-worms.

Bread tree.

The *careb*, or St John's bread tree, is more plentiful, and the long thick pods which it produces are exported in considerable quantities to Syria and Egypt. The succulent pulp which the pod contains, is sometimes used in these countries in place of sugar and honey, and is often employed in preserving other fruits.

Cotton.

The cotton of Cyprus is the finest, and brings a higher price than any in the Levant, or Archipelago; but the plains which were once covered with this plant, preserve only the shadow of its former culture.

Sugar canes.

The large plantations of sugar canes, which were reared with great success by the Venetians, and also the refining houses which they had erected, were burnt down or destroyed as soon as it fell into the hands of the Turks; and since that time, the culture of this plant has not been resumed. The gardens are, in general, full of all kinds of vegetables, particularly cauliflowers, which are here excellent; and abound with various sorts of flowers of the most brilliant lustre, and with aromatic plants, which diffuse their fragrance far around.

Fruits.

Apricots, plumbs, melons, cucumbers, and many different varieties of the gourd or pumpkin are produced in great plenty; and orange trees, lemon trees, pomegranate and other fruit trees, form groves around many of the habitations. Opium is cultivated at the foot of Mount Olympus; and madder, coloquintida, and soda, are gathered in several parts of the island. The forests, which are very abundant in the south-western district of the country, and likewise many places in the northern region, afford very fine wood for building and planks, and also plenty of tar and pitch; and the turpentine of Cyprus is equal to any in the world.

Forests.

Their chief attention, however, is given to the vine, which grows here in such perfection, that there is perhaps no place in the world where it yields such redundant and luscious fruit; and "the wine of this island," says Dr Clarke, "is so famous all over the Levant, that in the hyperbolical language of the Greeks, it is said to possess the power of restoring youth to age, and animation to those who are at the point of death." The best is the *Commanderia*, so named, because the district which produces it formerly constituted a part of the great commandery of the Templars and of the Knights of Malta, and is comprised between Mount Olympus and the towns of Limasol and Baffa. Limasol also produces the best Muscadine wine in Cyprus. They are both white wines, and when new have a slight violet tinge, which they lose by age, and then keep the colour of Madeira. The Commanderia is so strong, that it is preserved in casks, to which the air has constantly access, and may be kept in this way for any number of years. When it has stood a year, it is supposed to have passed the requisite proof, and then sells for about three-pence sterling the English pint. A very ancient custom prevails among the inhabitants. When a child is born, they bury large vessels filled with this kind of wine, which are not taken up but for the marriage festival of the same child. These being closely stopped, and preserved secure from the impression of the air, the wine is so improved, that it is considered as a great delicacy. All the wines intended for exportation are collected at Larnica, and kept there until they are shipped.

Cyprus.

Wines.

Mineralogy.

Though Cyprus be capable of the highest cultivation, and may be made one of the most productive islands of its size in the world, it is equally remarkable for the riches which it contains in its bosom. But these also are rendered useless by the despotism of the government, as all boring in search of mines is strictly prohibited. Gold mines were formerly wrought in this island, but they have been for ages abandoned, and the places where they were found cannot now with certainty be pointed out. Its copper was, in ancient times, the finest in the world, and its rich mines furnished the first blocks of that metal which were brought into use. The island was even distinguished by the epithet Ærosa, *Copper Island*; and the city Amathus, whose site is now occupied by Limasol, was characterised by Ovid as *gravida metallis*. These mines, however, lie neglected in the bowels of the mountains which contain them, as well as zinc, iron, tin, and other minerals, for which Cyprus was so famous. There are numerous quarries of plaster and marble in the island; and talc is very common, especially near Larnica, where it is employed for white-washing houses. The high mountains contain also emeralds, amethysts, peridots, opals, agates, &c. The Cyprian jasper was esteemed by the ancients as superior to the Egyptian, and is surpassed only by the Scythian; and fragments of very fine red jasper are frequently found in the bed of the river Pedieus, not far from Nicotia. In the rocks is found a beautiful variety of crystallized quartz, called by the natives *Baffa diamond*, because it is procured in the neighbourhood of that city. Amianthus of a very superior quality is also found near the same place. According to Dr Clarke, it is as flexible as silk, and perfectly white; finer and more delicately fibrous than that of Sicily, Corsica, or Norway; and the Cypriots call it the *cotton stone*. It was this mineral which the ancients used for making a kind of incombustible cloth, and the principal manufacture was established in Cyprus, as the materials were

Cyprus.

found here in abundance and perfection. It has been supposed, that the art of making this cloth is unknown to the moderns; but, according to the author already quoted, the inhabitants of a certain district in Siberia are in the practice of preparing thread, by mixing flax with this substance, and then spinning it. After weaving with this thread, the cloth is exposed to the action of fire, which consumes the flax, and leaves an incombustible web. But of all the mineral riches which this island contains, the inhabitants are allowed by their Turkish masters to trade only in yellow ochre, umber, *terre verte*, and salt. This last, when Cyprus was subject to the Venetians, was a very considerable article of exportation, and a great source of revenue, and annually constituted the sole cargoes of seventy large ships. A few country barks, however, are now sufficient for this branch of export trade. The great lake, or salt marsh, where the salt is formed, is in the neighbourhood of Salines, and was formerly three leagues in circumference; but the canals by which the lake communicated with the sea being now much choked up, the water scarcely covers a space of a league in circuit. The evaporation of the water is accelerated by the heat of a burning sun, and there remains a thick crust of salt, which is gathered in the month of September into pyramidical heaps. It then acquires consistence and hardness, and will even resist the winter rains. In the spring it is put on board small vessels, and conveyed to the neighbouring coast.

Animals.

Among the animals of Cyprus, those termed domestic have degenerated like their masters. They have also greatly decreased in number; while snakes, and other hurtful and hideous reptiles, have been allowed to propagate, and to cover the fields. Tarantulæ, with a black and hairy body, and yellow and brilliant eyes, are here not uncommon; and a large spider is sometimes met with, called by Sonnini the *galcode* of the Levant. According to this author, it is about an inch in length, "has a body of a livid yellow, and beset with long hairs, and even with prickly ones in several places. It runs with prodigious swiftness, and thus more easily escapes its destruction, in which mankind are interested, its bite being very dangerous, and its venom very subtle. The parts which are attacked by it swell in an instant, and occasion excessive pain, followed by certain death, if proper remedies be not speedily applied."

Manners and dress of the inhabitants.

The Cypriots are, in general, tall and well made, with an open countenance, and noble and agreeable manners; but they are said to be the most cunning and knavish of all the Greeks. They are, however, remarkable for their hospitality, which they exercise in a most generous manner; and are also very gay, and much attached to show and pleasure. "The women of Cyprus," says Dr Clarke, "are handsomer than those of any other Grecian island. They have a taller and more stately figure; and the features, particularly of the women of Nicotia, are regular and dignified, exhibiting that elevated cast of countenance so universally admired in the works of Grecian artists." They seem, however, to take very great pains to disfigure their natural beauty, by an unbecoming dress, and a profusion of ornaments. The waist is made as long as possible, and the legs consequently short; and though they are naturally corpulent, yet they use no endeavours to diminish the size of their bodies by lacing, but are rather vain of their bulk. The upper robe of the higher classes is always made of crimson, scarlet, or green silk, embroidered with gold; and they wear long scarlet pantaloons, with yellow boots, and slippers of the same colour. Their head dress is a kind of *Calathus*, which is worn by all ranks. Their hair is dyed of a fine brown colour with *henna*, and hangs down behind in long strait braids, with a few ringlets near the face; and from the head, and around the neck, are suspended a profusion of coins, chains, and other trinkets.

Diseases.

The fevers which prevail in this island are almost always malignant, while those experienced in other parts of the Mediterranean are in general intermittent. The inhabitants are consequently obliged to be very careful of their diet; and they consider it fatal to eat flesh of any kind in hot weather, unless it is boiled to a jelly. Fat meat they dare not touch, and they likewise carefully abstain at that season from eggs, cream, milk, and all sorts of pastry.

Manufactures.

The method of grinding corn between two stones, called *querns* in Scotland, is still in use here, and is also common throughout all Palestine. This employment is confined solely to the women; and the operation of grinding is frequently repeated, as they seldom prepare more at a time than what is necessary for present use. The prevalence of this ancient custom shews the rude state in which the inhabitants of these countries are with respect to the arts and refinements of life. Indeed the Cypriots have lost, along with their liberty, both the means and the power of profiting by the progress of civilization in other countries. Their only manufacture worth mentioning, is the preparation of Turkey or Morocco leather. It is carried on chiefly at Nicotia, and in the neighbouring villages; and the workmen pretend that they have a particular method of preparing it, which they keep as a secret. It is certainly both better dressed, and the colour is more durable and more brilliant, than what is made in the other parts of Turkey. They have also a manufacture for printed calicoes, and some other cloths made of silk and cotton. So far back are they in the arts, however, that such stones found in the island as are capable of being polished, must be sent to Grand Cairo for this purpose.

Commerce.

The commerce of Cyprus is now very inconsiderable; and the only place in the island where trade is carried on with any degree of activity is at Larnica. Their principal exports are about three thousand bales of cotton, but of which thirty thousand bales were annually exported by the Venetians; twenty thousand bales of silk of various colours, besides the floss, which is also exported to the ports of Turkey and Europe; the fruit of the careb tree; wine; salt; a considerable quantity of wool; Turkey leather; calicoes; and some cloths. For these, they receive in return woollen cloths, sattins, light stuffs, laces, metals, India spices, colonial produce, &c.

Present state.

Since the conquest of Cyprus by the Turks, its most valuable productions and riches have vanished, and its inhabitants have gradually fallen from the high station which they held when under the Venetians, to the most abject state of apathy and indolence. Every branch of industry and refinement is stamped with a deep impression of Turkish despotism. "The rigours of an oppressive domination," says M. Sonnini, "have shed their baneful influence over fields, arts, and men. Every day we see commerce fail, industry decay, lands dry up, and agriculture become impoverished. Vallies once shaded by useful or agreeable trees, which culture enriched with harvests of every species, or adorned with verdure and flowers, now remain uncultivated, and overrun with brambles, and other stubborn, meagre, and useless plants. One may travel whole days in plains, deserted and abandoned to that mournful and pernicious fecundity, which, on lands impatient to produce, is sterility's constant companion; in factitious wastes, the gloomy and fatal effects of the power of the evil-minded, where the traveller would think himself buried in vast solitudes, did he not here and there perceive straggling flocks and scattered habitations. Every day too, we see population, which increases and settles only where are to be found abundance of provisions, activity of trade and of manufactures, and justice on the part of government, diminish in a perceptible manner; and men quit a desolated country, and, for the most part, seek spots less disturbed, abodes less unhappy." The account which Dr Clarke has given us of the present state of this island, is equally melancholy, and affords an ample lesson of a tyrannical and selfish policy. "Instead of a fertile land," says he, "covered with groves of fruit and fine woods, once rendering it the paradise of the Levant, there is hardly upon earth a more wretched spot than it now exhibits. Few words may forcibly describe it: Agriculture neglected—inhabitants oppressed—population destroyed—pestiferous air—contagion—poverty—indolence—desolation. Its antiquities alone render it worthy of resort; and these, if any person had leisure and opportunity to search for them, would amply repay the trouble. In this pursuit, Cyprus may be considered as yet untrodden."

The frequent emigrations from this island, on account of the oppressive exactions of its rulers, has so reduced its population, that it rarely exceeds sixty thousand persons, a number scarcely sufficient to have peopled one of the ancient towns. The governor is annually appointed by the Capudan Pacha, who generally sells this office to the highest bidder. Every new master is consequently regarded as a tyrant more to be feared than his predecessor, and his short year of dominion is spent in the most unbounded rapacity, in order to recompense himself for the expenditure by which his sovereignty was obtained. CYRUS THE GREAT, the founder of the ancient Persian empire, is generally believed to have been the son of Cambyses, king of Persia, and of Mandane, daughter of Astyages, king of the Medes. He was born probably about the year 590 B. C. The biography of this mighty conqueror, however, is inextricably involved in the obscure mazes of contradictory statements and fabulous traditions. The circumstances attending his birth, his education, his expeditions, and his death, may all be regarded as historical problems for the exercise of learning and ingenuity, rather than as authentic facts to be implicitly believed upon the credit of any of the ancient annalists.

According to the recital of Herodotus and Ctesias, Cambyses, in consequence of a dream, ordered the infant Cyrus to be destroyed, and committed the execution of this order to his chief minister, Harpagus. Harpagus, being unwilling to execute this barbarous order himself, gave the infant to the king's shepherd, whose wife happened, at that very time, to be delivered of a dead male child. Being greatly taken with the appearance of the royal infant, she persuaded her husband to preserve him, and expose their own in his stead; and Cyrus was accordingly brought up as their son. Having grown up to manhood, he, after various adventures, dethroned his grandfather Astyages, conquered Crœsus, king of Lydia, overthrew the empire of the Babylonians, published the famous edict by which the captive Jews were permitted to return to Jerusalem and to rebuild the temple; then, pushing his conquests still farther, after a wonderful career of success, created an extensive empire in Asia, which was bounded on the east by the river Indus, on the north by the Caspian and Euxine seas, on the west by the Ægean Sea, and on the south by Ethiopia and the Arabian Gulf. At length, having carried his arms against the Scythians, or Massagetæ, he was defeated and slain in battle by their queen, Tomyris, who caused his head to be cut off and put into a leathern bag full of blood, with these sarcastic expressions—*Now glut thyself with blood, for which thou hast ever thirsted.*

Xenophon relates the history of Cyrus in a manner considerably different. But the *Cyropædia* was evidently written with the view of delineating, for the instruction of sovereigns and of statesmen, the model of a perfect prince, and a well-regulated monarchy; and not with the design of exhibiting a faithful record of historical facts. The narrative of Xenophon, however, has been scrupulously followed by Rollin, and most of the modern compilers of ancient history. There is, indeed, little discrepancy, among ancient authors, in regard to the grand historical features of his reign; the disagreement chiefly respects the birth, education, death, and character of the hero.

According to Xenophon, the education of children was regarded by the ancient Persians as the most important duty, and the most essential part of government. Boys were brought up publicly, in an uniform manner, and accustomed, from their infancy, to gymnastic exercises, and to the utmost temperance in eating and drinking. Cyrus himself was educated in this manner; and, according to Xenophon's account, surpassed all of his age in aptness to learn, and in courage and address in executing whatever he undertook. We cannot afford room to enter minutely into the circumstantial detail of the elegant Grecian biographer. Suffice it to mention, that, after passing through the elementary classes, to the previous discipline of which the Persian youth were subjected, Cyrus was, at length, initiated into the actual business of war; being intrusted with the command of the troops which were sent to co-operate with the forces of his uncle Cyaxares, who had succeeded Astyages on the throne of Media, and was involved in a contest against the Babylonians. In all his campaigns, Cyrus displayed uncommon address and military genius; and was no less renowned for the generous and benevolent virtues, than for courage, prudence, and warlike abilities in the field. We have already observed, that, in regard to the principal historical events of his reign, there is not any very material difference between the narrative of Xenophon and those of other ancient authors. These events will be related hereafter, in the article PERSIA. But, according to Xenophon's account, Cyrus, instead of falling in battle, died quietly in his bed, after a long and prosperous reign, full of years and of glory. Plutarch relates, in the life of Alexander the Great, that the Macedonian conqueror, when in Persia, having found the tomb of Cyrus broken open, discovered the following epitaph, in the Persian language. *O man! whosoever thou art, and whencesoever thou comest (for come I know thou wilt), I am Cyrus, the founder of the Persian empire. Envy me not the little earth that covers my body.*

It is not an easy task, at this extreme distance of time, to reconcile these contradictory statements of the ancient historians, or to separate what is true from what is false or fabulous in their various narratives. But to us, Cyrus appears to have been one of those able and enterprising men, who have frequently appeared on the theatre of Asiatic history; who, possessing talents far superior to those of any other man of his age and nation, had the address to unite the whole of the different Persian tribes under his own dominion; as, in a later age, Gengis-Khan contrived to get himself placed at the head of the Mogul hordes. The time of his appearance was fortunate; the empire of the Medes and Babylonians was already upon the decline; and that of the Lydians, under Crœsus, had not yet acquired a solid foundation. That Cyrus, as a prince and a statesman, possessed great and good qualities sufficient to entitle him to much of the praise which has been lavished upon him, there seems little reason to doubt; that he was deeply infected with the common vice of all great conquerors, an insatiable ambition, is evident enough from the history of his eventful career. That Xenophon purposely magnified the virtues, and embellished the exploits of this powerful conqueror, appears to be generally admitted; and his object in doing so has been already explained. But, at the present day, it were difficult to point out what portion of the traditionary character of Cyrus is with justice ascribed to him, and what portion is to be imputed to the lively fancy and inventive genius of his biographer. See *Rollin*, B. iv. ch. 1.; Millot, *Hist. Ancienne*, tom. i.; *Memoires de l'Acad. des Inscript.* tom. vi. & vii.; and Bayle, *Dict. Hist. et Crit.* v. CYRUS. (*z*)

CZAR, or TSAR. See RUSSIA.

CZARSKOSELO, or TSARSKOSELO, the summer residence of the Russian sovereigns, is about 22 versts from St Petersburg, between that city and Novogorod. The palace is built of brick, and has a front which extends nearly eight hundred feet. It is all plastered over, and is covered with columns, pilasters, and cariatides, all of which are gilt. The rooms are gaudy and spacious, and the walls of one of them are entirely covered with pictures, by the best of the Flemish and other masters. They are all fitted together, without frames, and without any arrangement; and it is said, that the vacant spaces were filled up with pictures cut down to suit the spaces that were left. The most interesting apartment in this palace is a room about 30 feet square, which is covered on all sides with amber, which was a present from the King of Prussia. In the apartment fitted up for Prince Potemkin, the floor was covered with different kinds of exotic wood, interlaid; and it is said to have cost an hundred roubles for every square archon.

The ball-room is an hundred and forty feet long, and fifty-two feet wide; and is two stories high. In another apartment, the walls, pilasters, and tables, were adorned with *lapis lazuli.* The cabinet of mirrors is a small room, lined with large pier glasses, and looks into a terrace, where there is a covered gallery, above two hundred and sixty feet long. The chapel is made wholly of gilt wood, and is richly decorated.

The gardens are laid out in the English style, and contain many statues in marble and bronze. A small flower garden conducts to the bath, which is adorned with agates, jasper, and marble statues and columns. The grotto is likewise ornamented with various minerals, formed into columns, vases, busts, and bas-reliefs, the most interesting of which is a vase, composed of precious stones, from Siberia. The rostral column, erected to Orlof, in memory of the naval victory gained at Tchesmé, over the Turks, is seen from this grotto, upon a lake. Among several bridges, Mr Coxe was particularly struck with one, built after the model of the Palladian bridge at Wilton, the seat of Lord Pembroke. It is of the same size, but of superior magnificence, the colonnade being of marble, and the lower part of granite. The marble was wrought in Siberia, by an Italian artist, who took nine years to finish it. There is a large court before the palace, encircled with low buildings, for the kitchens and out-houses.

On the road from St Petersburg, the versts or distances are marked by columns of marble, jasper, and granite; and when the court is at Czarskoselo, there are 1100 globular lamps lighted. This palace was built by Catherine I. but received its principal embellishments from the Empress Elizabeth. It was the principal residence of Catherine the Great, during the latter part of her life. See Storch's *Picture of St Petersburg*; Reinbeck's *Travels from St Petersburg in 1805*, Letter xi.; Coxe's *Travels in Holland, Russia, &c.* vol. ii. p. 199, 200; but principally Clarke's *Travels*, vol. i. p. 16—21. D.

Daca || Daghestan.

DACA, or DACCA, a town of Hindostan, in the eastern part of Bengal, is situated upon the eastern branch of the Ganges, about 100 miles from its embouchure, and is the capital of a province of the same name. As the Daca river communicates with the other inland navigations, and as the country is very fertile, this place has long been the emporium of a great inland commerce. It is reckoned one of the most disagreeable towns in India, being composed of a prodigious number of thatched houses built with mud, with a few brick houses in the Moorish style scattered up and down. Daca is famous for the great trade which it carries on in muslin and cotton cloths, and at one time it supplied the coasts of Delhi and Moxudabat, by means of agents resident in the town. Daca is reckoned the third city of Bengal in extent and population; and it was once the capital of Bengal. The remains of a strong fortress are still to be seen. (*w*)

DÆMIA, a genus of plants of the class Pentandria, and order Digynia. See BOTANY, p. 179.

DÆMONIACS. See DEMONIACS.

DAGELET, the name of an island in the sea of Japan, situated at the distance of 20 leagues from the coast of Corea. It was discovered by the astronomer whose name it bears, and who accompanied the unfortunate La Perouse. Excepting at seven small sandy creeks, at each of which there is a landing-place, the island is encircled with a perpendicular wall of rock. The circumference of it is about 9 miles, and the whole of its surface is covered with the finest trees, which, it is probable, the shipwrights of the Corea use for building vessels. La Perouse saw on the stocks several boats of the Chinese form. There were a few huts in the island, but no appearance of cultivation. Krusenstern, in his late voyage, passed to the east of this island. East longitude, according to solar observations, 130° 57′ 22″, North latitude 37° 22′ 18″. See La Perouse's *Voyage*. (*j*)

DAGHESTAN, or DAGESTAN, or DAUGHESTAN, is a province of the kingdom of Persia, stretching along the west coast of the Caspian Sea, and lying on the southern side of the highest ridge of Mount Caucasus. It is bounded by the province of Schirvan on the south, the Caspian Sea on the east, the province of Kumuk on the north, and Georgia on the west. As the name Daghestan implies, the province is almost wholly mountainous, the plain having a considerable breadth only towards Kumuk.

The districts which compose this province are five, Lesgestan, Schamgol, Uzmey, the khanship of Derbund, and the domain of Tabasseran. The district of Lesgestan, which consists chiefly of a range of lofty mountains, extends in a south-easterly direction, and forms the whole of the north-east boundary of Georgia. This district, which is very long and narrow, is inhabited by the Lesgi, or Lesghaes, a savage race, divided into different tribes. Their houses are perched upon the tops of the mountains, and on the most tremendous precipices. Ravines, and gulfs of unmeasurable depths, are joined by stone or wooden bridges of the greatest strength; and the most precipitous rocks are crossed by roads. Spring water is conducted every where by pipes, or by canals excavated from the solid rock, and the course of streams is turned to answer their purposes. From the poverty of the soil, and the small quantity of level ground in the district, the inhabitants form artificial terraces on the sides of the mountains, and thus raise crops on the most barren and inaccessible rocks. The Lesgaes are the scourge of the surrounding countries, whose villages they lay waste, carrying off the inhabitants as slaves. They are chiefly Mahomedans, and those who have not yet embraced the faith are sunk in the grossest idolatry. In consequence of their great bravery, the Lesgaes are hired to fight for their neighbours at the rate of 12 roubles a campaign, which lasts only three months; and it often happens, that they fall by the hand of their own brothers or relations. They dress after the Tartar fashion, and their arms are a gun, pistol, dagger, and sabre. The Lesgae women excel in beauty and symmetry all the other females of Mount Caucasus, and bring the highest prices in the market of Constantinople.

Daghestan.

The district of Schamgol, Schamchol, or Schabaal, which lies in the northern part of Daghestan, is about 100 versts long, and 55 broad. The plain is cultivated, and produces corn, being well-watered by the rivers that descend from the mountains. The houses of the inhabitants are situated on the mountains, and the sheds for their cattle are erected on the plain. The capital of the district is Tarki, which is situated in north latitude 42° 50′ on the Caspian Sea, in a narrow glen, through which runs a number of streams of salt water. It is said to contain 10,000 inhabitants, among whom are many Armenian and Georgian merchants. The town of Buinaki, or Boinak, situated in the same district, stands on a rivulet of the same name, at its exit from the mountains. The district of Uzmey is situated between two small rivers, the Urusai Bulak and the Little Darbach, and extends about 60 versts along the Caspian, and about the same distance in breadth. It is chiefly mountainous, but is well inhabited, and produces abundance of wood and corn. It is watered by three large rivers, the Chamraseni, the Great Buam, and the Great Darbach, which are divided into small canals for the purposes of navigation. The residence of the Uzmey is at Bashli, a small town upon a river of the same name, between Tarki and Derbund.

The khanship of Derbund, or Derbent, is only about 30 versts long, and 12 broad. It lies between the rivers Darbach and the Rubas, and forms a broad and partly marshy level, intersected by numerous rivulets, and adorned with many beautiful and well cultivated corn fields. Derbund, the capital of this district and of the whole province, occupies the site of the ancient Albania, and stands in north latitude 41° 52′. It is encircled with a wall and towers, and has a citadel erected on the top of a rock, but at too great a distance either to defend the town or the harbour. A portion of the famous wall of Gog and Magog, which is said to have reached to the Black Sea, is still to be seen near the citadel. It stretches to the west over precipitous mountains, and is extremely solid. The splendid aqueducts erected by the Arabians being now in ruins, water is procured very scantily from wells. Derbund

Dago
||
Dahomy.

was taken by the Arabians, and called by them Babe-ul-islam, (the gate of faith); but since 1796, it has been in the possession of the Russians. It contains about 647 houses, and its principal inhabitants are Armenians, Mahomedans, Jews, and Russians.

The district of Tabasseran is about 50 versts in extent, and reaches to the highest of the Lesghaen mountains. It lies between the Darbach and Rubas near their sources, and consequently to the west of Uzmey. The vallies are beautiful and fertile. The inhabitants speak a language of their own. According to Reinneg, they amount to 10,000, and the family of the reigning prince has held the supreme power for 600 years. The town of Tabasseran is the centre of the trade carried on between Russia and Daghestan. See Reinneg's *Historical and Topographical Description of Caucasus*, and Macdonald Kinneir's *Geographical Memoir of the Persian Empire*, p. 353—356. (π)

DAGO, or DAJEN, or DAGHO, the name of an island in Riga, belonging to Russia. It is about 34 miles long, and 24 broad. The southern and the eastern parts of the island have a good soil, consisting of a blueish clay, and produce a considerable quantity of corn. The western part of the island is very sandy. There are forests and abundance of stone in the island. The population is so great, that the estates are overburthened with vassals, many of whom go to the mainland, and employ themselves in embanking, bricklaying, &c. and it is said that whole families are frequently sold. The inhabitants are principally Esthonians, and there are whole villages inhabited by Swedish Boors. The principal places in the island are Rekki, Pegalep, Paden, and Dager-ort. The position of the lighthouse of Dager-ort, situated on a hill 130 feet high at the western point of the island, has been ascertained by astronomical observations. It lies in east longitude 22° 9′ 15″, and north latitude 58° 56′ 1″. (π)

DAHALAC. See DHALAC.

DAHLIA, a genus of plants of the class Diœcia, and order Monandria. See BOTANY, p. 353.

DAHOMY, a kingdom of Africa, often called by the inhabitants FOY, is situated on the northern side of Guinea, of which it forms a part, and extends 150 or 200 miles inland. The boundaries of the kingdom have not been exactly ascertained by travellers, but its capital Abomy lies in about 9° 50′ N. Lat. and between 3° and 4° E. Long. Of the inland kingdoms, that to the west is called Mahee, and that to the north-east Eyeo. Till the beginning of the 18th century the Dahomans were an inconsiderable nation, known by the name of Foys; and the town Dawhee, which lies betwixt Calmina and Abomey, about 90 miles from the sea-coast, was the capital of their small territory. But by conquering and annexing to their dominions the kingdoms of Whydah, Ardrah, and Jacquin, and thus extending their boundaries to the sea coast, the country became better known to modern geographers; and the English, French, and Portuguese, erected and maintained forts in it for the protection of the slave trade. As these countries now form a part of the Dahoman kingdom, they will be included in our description of it.

History.

The present name Dahomy, is said to have been derived from the following fact in the history of the country. In the beginning of the 17th century, Tacoodonou, chief of the Foy nation, basely murdered a neighbouring prince who had paid him a friendly visit. He then attacked and took Calmina, the capital of the deceased. Strengthened by that acquisition, he declared war against Da, the king of Abomey, who soon fell into his hands; put Da to death by cutting open his belly, and placed his body under the foundation of a palace, which he built in Abomy, and which he called *Dahomy;* from *Da,* the unfortunate victim, and *homy,* a belly; that is, a house built on Da's belly. After that conquest, he fixed his residence at Abomy, and assumed the title of king of Dahomy; his ancient subjects still retain in that country the name of the *Foys,* but to Europeans they are known by the name of Dahomans.

Dahomy.

In this manner Tacoodonou conquered Abomey, and founded the Dahoman empire, about the year 1625. He was succeeded by Adaunzou I. in 1650, and by Vibagee in 1680; but little of the history of the country is known till Trudo enlarged the boundaries of the kindom, by adding to it by conquest the kingdoms of Ardrah, Whydah, and Jacquin, betwixt the years 1708 and 1727. This people, like the other Africans, have no other records of history than the traditionary legends of their bards; and their kings forbid any transactions to be mentioned which might reflect disgrace upon them or their ministers. The character of Trudo is very differently drawn. By some he is represented as extremely cruel to those who opposed his arms, but mild and generous to the vanquished; remarkable for his kindness to Europeans, and exhibiting many traits of a great and generous mind. By others it is affirmed, that his policy was that of an ambitious and brutal savage, who sought to retain the territories he had gained by the horrid cruelty of burning the towns and butchering the inhabitants; and that his reign entailed lasting calamities on his country. He died in 1732, and was succeeded by his son Rossa Ahadee, who is described as tall in his person, graceful in his manners, polite to strangers, but the terror and scourge of his own subjects. During a reign of upwards of 40 years, his country was wasted by wars foreign and domestic; and the mind is filled with horror at the recital of the many sacrifices of human victims, for the purpose of *watering* (according to the expression of that country) the graves of the deceased royal family. In 1774, he was succeeded by Adaunzou II. by whose authority these, and similar barbarous customs, of which we shall take some notice, still continued to be sanctioned.

Soil and productions.

The country lying behind Whydah, rises with a gentle and gradual ascent for about 150 miles from the sea, before there is any appearance of a hill or mountain; and to the extent of 400 miles into the interior it is covered with verdure, with open plains of grass, and some woods and forests. The surface is generally a loose sandy soil; below that is a reddish earth; and what is very remarkable, there is not a stone to be found in it of the size of a walnut. The villages are pretty large and numerous. The houses are constructed of mud walls, and covered with straw; and are generally built at such a distance from each other, as to admit betwixt them patches of cultivated ground.

Of fruits and vegetables, the country yields a plentiful supply, in proportion to the care bestowed on their cultivation. Pine apples, melons, oranges, limes, guavas, and other tropical fruits, are to be found here in great variety. The soil also produces abundance of maize, millet or Guinea corn, pease, and beans. They likewise cultivate yams and potatoes, the plantain, the banana, and the cassada or *manioka;* which, in tropical climates, is the cheapest of all the substitutes for bread. A fruit of a very remarkable quality is produced in this country, as well as in some other parts of Africa. In size and shape it resembles a

Dahomy.

Soil and productions.

small olive, and is of a dusky-reddish colour. The pulp is firm, and almost insipid; the stone hard like that of the olive. After chewing the fruit, a glass of vinegar tastes like sweet wine, a lime has the flavour of a ripe orange; and the same change is produced upon other acids, the berry having the surprising quality of converting acids into sweets. Like the other inhabitants of tropical climates, the Dahomans plant twice a-year, viz. at the vernal and autumnal equinoxes, after which the periodical rains set in. They may, indeed, be said to reap four, or rather two double crops; for soon after the maize appears above ground, they plant *callavanas* betwixt the rows, which gives the fields a very beautiful appearance. Whydah is a very fertile country, but to Europeans the heat of the sun is almost insupportable.

Nor is the country destitute of various productions adapted to commerce and manufacture. Of these, the following may be accounted the chief: the *indigo* plant, which is very common, but the natives cannot prepare it for market: *tobacco*, which in several places grows spontaneously, but also requires the hand of a European to prepare it for use: *cotton*, which the natives manufacture into cloth for their own use: *pepper*, of the same species, and scarcely inferior in flavour to that of the East Indies: the small *berry* just mentioned, which serves as a substitute for sugar: *palm oil*, a very valuable production, which is exported in large quantities for the use of the British wool-combers and soap-boilers; when mixed with potash, it is manufactured into a very good soap: and *peltry*, such as tiger and leopard skins, &c. but which are not of great value. Besides these, there is an infinite variety of other valuable productions scattered over the country by the liberal hand of nature; but the natives are indifferent to the blessings that surround them.

Character and manners.

Like other Africans, indolence is the most prominent feature of their character. The men sleep and smoke, enjoying in thoughtless security the present moment, and regardless of the future; while the whole labour of agriculture devolves upon the women. Indeed, the general torpidity of this people justifies a common remark, that in Africa, in proportion as the soil is fruitful, the inhabitants are averse to industry. They are warlike, keep a secret inviolable, are much addicted to plunder, and even make a merit of robbing the white people. The Negro is very hospitable to other Negroes; is in general sober, and goes to excess only in drinking brandy; but he is vindictive, lying, and obstinate; and yet he cannot be denied the character of gentleness. They are very cleanly in their persons, and particularly so with regard to their food. Their bread is made of maize or millet, sometimes baked, and sometimes boiled into a thick pudding; and their chief dish is a soup, composed either of flesh or fish, with a variety of vegetables, enriched with palm oil, and well seasoned with pepper and salt.

Dress.

The dress of the Dahomans is light, and suited to the climate. That of the men consists of a pair of striped or white cotton drawers of the manufacture of the country, over which they wear a large square cloth of the same, or of European manufacture. The head is covered with a beaver or felt hat; the arms and upper part of the body are naked, except when travelling or performing any work; then the large cloth is thrown off, and the body covered wich a frock without sleeves. The feet are always bare, for none but the sovereign is permitted to wear sandals. In the hand is usually carried either a cutlass or a wooden club; and every person is provided with a tobacco pouch, which contains also a flint, steel, and tinder. In war they paint their faces and bodies, which gives them a most terrific appearance. The women wrap cloths and handkerchiefs round their bodies; their necks, arms, and ancles are adorned with beads and cowries, and their fingers with rings of silver or other metal. Both sexes are less addicted to the practice of cutting or *tattowing* the body than their neighbours; they make only a perpendicular incision, which leaves a mark between the eye-brows. In Whydah, they cut their foreheads and cheeks in such a manner, as to give them the appearance of being much pitted with the small-pox; and the women mark the lower part of the body with various devices.

Marriage.

When a young man wishes to marry, he makes his proposal to the young woman's father, who consults his daughter. If she consents, the marriage contract is concluded, and the bridegroom makes a present to his father-in-law of cowries and brandy. When the young woman is marriageable, the husband is informed, who, as soon as the marriage is consummated, makes a present to the bride, and another to her father. The men may divorce their wives; and the women have an equal liberty of withdrawing themselves, without any formality, and of taking another husband. In such a state of degradation are the women held, that they must bend the knee when they present any thing to their husbands, rise up only with their permission, and never eat along with them, nor in their presence. As polygamy is sanctioned both by custom and law, a man may marry as many wives as he pleases; adultery, however, is punished with death; and, indeed, every instance of gallantry, in the married state, exposes the delinquent to death or slavery. But what tends more than any thing to eradicate all the parental aud filial affections, is a principle of the state, that parents have no property in their children. They are considered as belonging entirely to the king, and are taken from their mothers at an early age, and dispersed among the villages remote from the places of their nativity, where they remain subject to the king's future destination of them, and with little prospect of ever being again seen or recognised by their parents. This arises from the king's jealousy of family connections, which might lead to associations dangerous to his unlimited power. The consequence is the almost total extinction of parental affection and filial love. Parents, instead of cherishing, endeavour to suppress those tender attachments to their offspring, which they know will be violated as soon as their children reach the age at which they can be taken from them.

Manufactures.

From the shells of the *calebash* fruit they form, in a rude manner, their domestic utensils; and, with the implements of a forge very simply constructed, they contrive to fabricate not only the necessary implements of husbandry, but also carpenters tools, cutlasses, spears, and other warlike weapons. The anvil is of stone, or an old iron cannon; and the hammer is a thick piece of rounded iron, which they hold by one end. Besides blacksmiths, they have also braziers and silversmiths, who make bracelets, rings, and various trinkets of brass or silver. They make also earthern pots, water jars, and other utensils of the same materials. Nay, with looms of a very rude construction, they manufacture neat and durable cotton cloths, which are not only very valuable among themselves, but are also purchased by Europeans at a high price. Their dyes, especially their blues, are very durable. They make very neat

Dahomy. mats, and also weave cloths of the palm-tree leaves, which they sometimes dye, but more frequently wear in the natural colour, which resembles that of nankeen.

Animals. The country abounds with deer, sheep, and goats, (whose flesh is said to be equal to mutton,) hogs both wild and domestic; a variety of poultry, particularly the Guinea hens and Muscovy ducks; and the lakes are stored with mullets, carp, and other fish. The agouti, (called by the British traders *bush-cat*,) a gregarious animal, abounds in this part of Africa, and its flesh is accounted very delicate by the natives. It is about the size of a full grown hare, but rather thicker; and when divested of its skin, the body appears incased with fat. Like the hare, the hinder legs are longer than the fore legs, but the ears are short and rounded; the mouth is shaped like that of a rat; and the feet are small. The body is covered with stiff bristles, which it has the power of erecting, but which adheres so slightly to the skin as to be easily separated. They generally go in companies of fifteen or twenty in number, following one another in the same path, and their bite is very severe; but the natives, by attacking the rear of the party with sticks, are able to destroy two or three at a time. Their flesh is very fat, and tastes greasy and strong, unless when dried and smoked; a preparation which makes it exceedingly palatable. The markets are well supplied with provisions at reasonable prices, beef excepted, which is scarce in the country. On the coast of Whydah, a turtle of 100 pounds weight has been purchased for a single flask of brandy; and, indeed, a ship's company may be furnished there with fresh provisions at a cheaper rate, and in greater abundance, than on any other part of the coast. The elephant, though his flesh be coarse, is used for food by the natives; and dogs are fed for the same purpose.

Language. Their language is what the Portuguese call *lingua-geral*, or general tongue, and is spoken, not only in Dahomy *proper*, but also in Whydah and the other dependant states.

Religion. Their religion, like that of the neighbouring kingdoms, consists of such a mass of superstition as can hardly be described. The objects of their devotion are the sun and moon, various animals and trees, and other substances. The Portuguese word *fetiço*, or, as the English pronounce it, *fetish*, signifying witchcraft, has been adopted by most of the maritime natives of Africa, as well as by the Europeans who trade thither. Of their *amulets*, or *charms*, the principal is a scrape or parchment, containing a sentence of the Koran, which the natives purchase from the Moors who visit the country, and which they hang up in their apartments, and decorate with a variety of rude images. Among the objects of their idolatrous worship, is a species of snake or serpent called *Daboa*. It is quite harmless, and suffers itself to be handled, without appearing irritated; but there is another species which resembles it, and is very dangerous. When they meet the serpent *Daboa*, they put it into a basket, and place it in the temple destined for it, where they secretly feed it with rats, but pretend that it lives upon air. The temple is served by priestesses, supported at the king's expence. Every year there is a festival in honour of this serpent, at which the grandees assist, and for which the king supplies the necessary articles. It lasts usually seven days, during which time the people abandon themselves to drinking, music, and dancing. Great faith is placed in the serpent. Those who labour under bodily pains, apply the animal to the part affected; and pregnant women offer prayers to it for a favourable delivery. The tyger is also held in veneration; and there is a temple dedicated to the Devil, or bad Dæmon. Notwithstanding these superstitions, the people have a confused idea of a Supreme Being, all-powerful and infinite, whom they endeavour to propitiate by their *fetish*; but pay him no other worship, as they are convinced that he is too good to do them any evil.

Government. The government of Dahomy is the most complete despotism that can be found on the face of the earth. All ranks are in the lowest degree of subordination to the king; and all acknowledge his right to dispose of their persons and property at pleasure. On his entrance at the palace-gate, the highest officer of state crawls on his hands and knees till he arrives in the royal presence, where he prostrates himself, rubbing his head in the dust, and uttering the most humiliating expressions. In the same abject posture he communicates his business, and receives the commands of his sovereign. Nevertheless, he receives strangers with courtesy. Ambassadors from foreign courts are permitted to salute the sovereign, according to the mode practised in their own country; European governors and masters of ships, are allowed to sit covered in his presence; and, as a peculiar mark of royal favour, he has been known to shake hands with a European. The reverence paid to him by his subjects, is a compound of love and fear, approaching to adoration. When Mr Norris asked a soldier, who was just going to battle, if he was not afraid of finding the enemy too strong, "I think of my king," said he, "and then I dare engage five of the enemy myself. My head belongs to the king, not to myself. If he pleases to send for it, I am ready to resign it; or if it is shot through in battle, it makes no difference to me; I am satisfied if I lose it by the order of my king." As the king is thus master of the lives, so is he also of the properties of his subjects. When a man is accused of a crime, he is condemned to slavery or death; his effects are then forfeited to the king; and his domestics, relations, and friends, are all seized, and either put to death, or sold for slaves; yet, whatever the king does, they are persuaded is right. A more abject submission, and a more despotic authority, are nowhere to be found.

Officers of state. The officers of state are, first, the prime minister, who is called *tamegah*, who ranks next to the king, aids him in the cares of government, and is the *only* person in his dominions whose head he cannot take off at pleasure. The next in rank is styled *mayhou*, another counsellor; is master of ceremonies; directs the public festivals; and has the care of all strangers. Upon the king's decease, these two officers have the power of setting aside the eldest son, and of nominating any of the other sons of the royal family whom they deem more worthy of the crown. They are also the judges in all criminal cases, and are constantly with the king, to inform him of every thing that passes in the kingdom. The commander of the army, which amounts to about 8000 men, is next in rank, and is styled *agaow*. And the last is the master of the horse, *jahou*, whose office is to take charge of the criminals, and see that their punishments be inflicted; to superintend the agriculture of the country; and supply the king's household with provisions.

Division into classes. The nation is divided into three classes; the merchants, the military, and the manufacturers. The merchants are the first in rank. The military, with the exception of the officers, who have a regular pay, are paid only when on duty. The soldier, in the time of peace, is employed in cultivating the ground, and in fabricating every thing he needs. Every one pays taxes, either in kind, or by composition. There are very heavy duties on every article of commerce, which are collected with great strictness by commissaries or officers stationed in every quarter of the country.

Barbarous ceremonies at the king's death.

The moment the king expires, a horrid scene commences in the palace. The wives of the deceased begin with breaking and destroying the furniture, and every thing of value that belonged either to themselves or to the late king. This destruction continues till the *tamegau* and *mahou* have announced the successor to the crown, and he has taken possession of the palace, which he does with all expedition, and that instant the desolation ceases. This barbarous custom may have originated in a laudable desire, either to accelerate the choice of a successor, in order to prevent a civil war, or to confirm the attachment of the people to a monarchical form of government, by disgusting them with the turbulence and licentiousness incident to democracy; or it may be no more than would happen in any country, where slaves are for a time released from the awe of a despotic power.

As soon as the decease of the king is made public, eight men dig a ditch, about 12 feet deep, and 7 long; then they erect a kind of couch, adorned with every thing that the deceased reckoned most valuable, which they place upon a stage enveloped with all kinds of cloths. Upon that stage they cause the eight men who have dug the grave to ascend, when their heads are instantly struck off, and their bodies thrown into the fields for food to the wolves and the birds of prey. Then appear a crowd of the king's women contending for the honour of being shut up in the tomb, to serve their late sovereign; 24 of these are selected, to the great grief and lamentation of the rest. To confirm these unhappy victims in their error, care is taken to put into the grave or tomb of the deceased king, a great variety of articles of food; and they are strictly charged to take great care of him, to sprinkle him with perfumes, to cover him with aromatic herbs, to give him drink and materials for smoking, and to burn incense every day about the body. They then contend for the honour of descending first into the tomb, which is afterwards shut, and covered with earth; and for five days guns are fired. After a certain time, they celebrate the great ceremony of the funeral, to which all the chiefs of the European factories, of the tributary princes, and of the governors of provinces, must repair, carrying with them a variety of presents. The whole concludes with the sacrifices of particular beasts, and birds, and human beings, to the manes of the deceased king; and their carcases are thrown into the fields, as food to the wild beasts.

A grand festival, which continues some weeks, is called the *annual customs*, at which the viceroy of Whydah, the governors of the forts, towns, and provinces, the Black merchants and traders, must attend with their presents, which consist of pieces of Indian damask, or other valuable silks; and, indeed, every head of a family must attend for a few days, and bring a quantity of cowries (the current money of the country), or some other present, proportioned to his circumstances. A particular account of this festival would not afford much amusement to our readers. It continues about a month, during which there is some public exhibition every fourth or market-day; the intermediate days being employed in preparations. One day is set apart for singing and dancing; and the performers are rewarded according to their merit. Another is allotted for feasting in the market-place, where tents are pitched for the king and his attendants, for the White visitors, and ambassadors from foreign states. The bards rehearse the whole history of their country, which continues for several days. The young men, prostrating themselves in the dust, beg to be favoured with wives. The females are handed out of the palace, and distributed among the petitioners; each must take the one assigned to him, and the cowries are received in return. The king informs himself particularly of the behaviour of his slaves; and, upon this occasion, the meanest have access to him, and have an opportunity of applying personally for redress. Various scenes are exhibited during this festival, which concludes with the erection of a large stage near the palace, on which are piled heaps of silesias, checks, calicoes, cotton cloths, a variety of other European and Indian goods, and a prodigious quantity of cowries. When all is ready, the king ascends the stage with his officers, and other persons of rank; and the whole of the goods are then thrown over the stage, among the surrounding multitude, for which a violent scramble ensues, to the great entertainment of all present. The whole festival itself would afford an amusing spectacle, were it not for the human sacrifices with which it is accompanied, for the purpose of *watering*, according to the country expression, the graves of the deceased royal family.

The Harmattan.

This country is frequently visited by the ***Harmattan*** wind, which indeed extends along this part of the coast of Africa, from Cape Verd at least as far south as Cape Lopez. It prevails in the months of December, January, and February, blowing from the north east; and continues one or two, sometimes five or six days at a time: it has even been known to last a whole fortnight, and there are generally three or four returns of it every season. It is always accompanied with an unusual gloominess and haziness of the atmosphere: the sun can be seen only for a few hours at noon, and assumes a red colour, which excites no painful sensation in the eye. In proportion to the distance from the sea-coast, the fog decreases; and, at four or five leagues from it, is scarcely discernible, but the wind is felt ten or twelve leagues inland. It blows with a moderate force; and, during its continuance, not the least appearance of moisture in the atmosphere is ever perceived. Salt of tartar dissolved in water, and exposed to the Harmattan, even in the night, becomes perfectly dry in a few hours. Vegetables of every kind suffer from it. The grass withers, and dries like hay; all tender plants are killed by it; the most flourishing evergreens feel its baneful influence; the branches of the trees droop, and the leaves become flaccid; and the fruits, robbed of their usual nourishment, are cramped in their growth, and become perfectly dry before they have arrived at half their usual size. In short, when it continues for some days, vegetation is completely checked, and every production of nature fades and withers. Nay, such is its penetrating quality, and so extremely dry is the atmosphere during its continuance, that the covers of books, shut up closely in a trunk, and protected by lying among clothes, have been found bent back, as if they had been exposed to a fire; the pannels of doors and window-shutters split; the sides and decks of ships become quite open and leaky; and casks containing liquor, if not frequently wetted all over, generally lose their contents. Nor are its effects on the human body less severe. The eyes, nostrils, lips, and palate, become dry and uneasy; and the mouth requires to be frequently moistened; the

Dairy.

lips and nose become chopped and sore; and though the air is cool, there is a disagreeable sensation of prickling heat upon the skin, as if it had been washed with spirits of hartshorn. If this wind continues for five or six days, the scarf skin peels off from the hands and face, and even from the rest of the body, if it continues a few days longer.

Such are the baneful effects of the Harmattan on animal and vegetable nature, and yet it is not unproductive of beneficial effects on the human system. In certain diseases it is conducive to health. It contributes to the cure of ulcers and cutaneous eruptions; of fluxes, and intermitting fevers; and, in all cases in which the frame has been relaxed, the nerves soon resume their former tone and vigour. Infection not being easily communicated in that dry state of the atmosphere, the Harmattan stops the progress of all epidemic diseases; and the small-pox, fluxes, and remittent fevers, not only disappear, but those who are labouring under these disorders, are blessed with a speedy and perfect recovery. See Dalzel's *History of Dahomy*; Norris's *Memoirs of the Reign of Bossa Ahadee*; and *Voyage à la Cote de Guinée*, par Labarthe. (A. F.)

DAIRY, a place where milk is deposited, and where it is manufactured into butter, cheese, and other articles of food. In some situations, the farmer brings his milk to market in its natural state, and then he is said to keep a milk dairy; in other situations he manufactures butter or cheese, and, in such cases, he is said to keep a butter or a cheese dairy. It is quite evident, that it must depend on circumstances, which of all these three sorts will afford the most profit. Within a few miles of a large town, where there is always a ready sale for milk and butter, and where the carriage is short, the milk and butter dairy will generally answer best; but where the distance from a market is considerable, the sale of milk in its natural state is out of the question, and the dairy farmer will probably find it necessary to engage in the manufacture of cheese.

Sir John Sinclair, in his *Account of the Systems of Husbandry adopted in the more improved Districts of Scotland*, states, that in the neighbourhood of Glasgow and Paisley, such farmers as live within two miles of these towns, sell their milk there when newly taken from the cow. Those who are from two and even to ten miles distant from town, generally churn their whole milk, and sell it and the butter in Glasgow or Paisley; and all who live at a greater distance make their milk into cheese. "The produce of these different modes," he says, "is in the proportion of 6d. per Scotch pint (that is two English quarts) for new milk, 4d. when churned, and sold in butter and butter milk, and 3d. when made into cheese." The nourishment derived from a pint of milk used fresh, is equal to that of two when made into cheese, together with the meat that is obtained from the whey when employed in feeding hogs. The dairy system is perhaps the most profitable, as well as the most pleasing, of all the parts of husbandry. It was certainly the earliest. Herbage may be converted into human food, either in the form of flesh or of milk; but it is calculated, that a much larger quantity of human food will be produced from the same quantity of herbage in the latter case than in the former. The herbage that would be sufficient to add 112 pounds to the weight of an ox, would, if employed in feeding cows, afford 450 English gallons of milk. This, if made into cheese, which is not the most advantageous way of consuming milk, would produce 430 lbs. besides the flesh that might be obtained by feeding hogs with the whey. The 112lbs. of beef, at the rate of 8s. a stone of 14lbs. would amount to L. 3, 4s.; but the 430lbs. of cheese at 12s. a stone of 24lbs. would bring more than L. 10, 10s. The trouble and expence, however, requisite to produce the cheese, would be greater than what would attend the production of the beef.

Buildings for the purposes of the dairy.

In the erection of such buildings as are necessary for dairy purposes, two things ought always to be kept carefully in view,—conveniency of situation, and the preservation of a proper temperature. If the buildings are inconveniently situated, much labour will be lost; and if the air in them be either too hot or too cold, no process will go on as it should do. Their size will be proportioned to the number of cows kept, and their interior arrangement to the business intended to be carried on, whether this be cheese-making, butter-making, or merely the preservation of milk for sale. A dairy-house for forty cows, may be twenty feet by sixteen; and for an hundred cows, forty feet by thirty. These are the usual proportions in the county of Gloucester. Ornament is sometimes studied in the erection of a dairy-house; and this, when it happens to be the case, will of course regulate in a great measure the situation of the building.

A butter dairy, when well constructed, consists of three apartments or rooms; one for depositing the milk, one for performing the operation of churning, and another for containing and cleaning the necessary utensils. A cheese dairy should consist of four rooms; a milk room as before, a room for making and pressing the cheese, another for the process of salting, and a fourth for stowing and preserving the cheeses, till they are ready to be brought to market. This last may be conveniently placed as a sort of loft over the other three. The milk dairy properly requires only two apartments, one for the milk, and the other for serving it out, scalding, and cleaning the different utensils. Temperature in a dairy is of the first importance; for, if too much heat be admitted, the milk will quickly become sour, and if too cold an atmosphere prevails, neither butter nor cheese making can be carried on with success.

Method of heating the dairy.

Different plans have been proposed for securing a proper degree of heat. Double walls and roof have been recommended by Dr Anderson; others have proposed hollow walls; and Mr Loudon, in his *Treatise on Country Residences*, thinks that, for common purposes, a vacuity of eight or ten inches left betwixt the wall and the lath and plaster, will be sufficient. A fountain, or *jet d'eau*, where such can be commanded, will always be a very agreeable and convenient acquisition in a dairy. Mr Marshall, who has paid much attention to this subject, advises that the walls shall be at least six feet thick, a foot on the inside to be of brick or stone, the outside to be constructed of sod, and the space between to be closely filled with earth. The roof, he says, should be of thatch, three feet thick at the least, and should project completely over the walls on each side. The materials of such a building being all bad conductors of heat, it would, he conceives, if provided with double doors, naturally preserve in this climate a temperature of about fifty to fifty-five degrees of Fahrenheit at all seasons of the year. But as the milk itself when brought in warm, would naturally tend in summer to raise the temperature too high, an ice-house is recommended to be attached to the dairy, of a simple and ingenious construction. A small quantity of ice placed when necessary in the milk room, would soon lower the temperature to any degree that might be wanted; and if the cold in winter should become too great, a barrel of hot water close stopped, or a few hot bricks placed on the floor or table of the milk room,

Dairy.

would readily counteract its effects. A chaffing-dish with burning coals should never be used, as it is apt to communicate a bad taste to the milk. Many other simple and cheap forms of dairy-houses are found to answer well. Mr Marshall tells us, that in Wiltshire the rooms of the dairies have commonly outer doors, which open under a penthouse or lean-to shed. This he considers as a great advantage, for it communicates, by affording shade, a beneficial degree of coolness to the whole building.

Utensils.

The utensils required in a dairy are principally the following: milk-pails, milk-strainers or sieves, milk-cowls, coolers or pans, milk-skeels or creaming dishes, lading dishes, skimming dishes, cheese ladders, cheese vats, cheese presses, and churns. The expence of all which must evidently vary in different situations, but it is believed, that a sufficient assortment of them for a dairy of twenty cows, may, in most cases, be provided for L.25 or L.30. Wood has, in general, been employed in their construction, and is probably upon the whole the most eligible material. Lead, brass, and copper, are altogether inadmissible; for the acid contained in milk (which is now known to be the acetic) combines with these metals, and forms with them poisonous compounds. The same may be said of earthen vessels glazed with lead; and it is obvious, that true porcelain, or glass, can never come into general use for dairy purposes. Cast iron itself is far from being unobjectionable, because though the acid of milk does not form with iron a compound that is poisonous, it forms with it one, which may, in a considerable degree, alter the taste and quality of dairy products. The least objectionable of all the metallic milk dishes, are probably those which have been lately invented by Mr Baird of the Shotts ironworks, in Linlithgowshire. They are made of cast iron, softened by annealing in charcoal, so as not to be liable to break by an ordinary fall, turned smooth in the inside, and laid over with a coat of tin, to prevent the iron from coming in contact with the milk. Even these, however, we do not think quite free from objection, because, though the iron comes not in contact with the milk, the tin does; and though the acetic acid acts upon tin only in a slight degree, still it acts upon it, and forms with it a compound, which when evaporated is viscid, and has a very fetid disagreeable smell. It may therefore be supposed to injure, in some degree, the products of the dairy. The Shotts milk dishes, however, are, we understand, coming very generally into use, and Sir John Sinclair pronounces their invention, "one of the greatest improvements that has lately taken place in regard to dairy management." They are much more easily kept clean than wooden dishes, and their superior power of conducting heat, cools the milk put into them so much faster, that Sir John says, "the farmers' wives, who have given them a fair trial, affirm that they throw up one third more cream from an equal quantity of milk." They are made at the Shotts foundery, from half an English quart to twenty-four in content, and their prices are from 1s. to 9s. 6d.

It has been lately found, that slate makes very good milk coolers; and in some of the midland counties of England, the common flag, or transition slate, has been employed for this purpose.

Dairy farms.

Dairy farms, in general, consist chiefly of meadow and pasture, with only a small portion of the land under tillage. But Mr Holland, in his *Survey of Cheshire*, and Mr Curwen of Workington, in the 5th vol. of *Communications to the Board of Agriculture*, have shewn, that stall-feeding with green crops, is a most important improvement in the management of cows. In this way, they can be kept in milk not only for a month longer in autumn than by the common modes, but even through the whole winter season. Mr Curwen's extensive experiments on this subject have put the matter beyond all doubt, and it is now, we believe, pretty generally if not universally practised.

The greatest dairy farms in Britain, are found in Cheshire, Gloucestershire, Buckinghamshire, Essex, Cambridgeshire, Dorset, and Suffolk, some of the midland counties, and in Ayrshire. Essex, Cambridgeshire, Suffolk, and Dorset, are chiefly famed for butter, the rest for cheese. It is more likely that a dairy farm of no very great extent, say of ten or twelve cows, will, if well managed, be profitable, than a large concern of this sort; for the farmer's wife and daughters can more readily superintend, or perhaps perform a great part of the dairy operations themselves, when the farm is of a moderate size; and this is always better done by them, than we can ever expect it to be by hired servants. Sir John Sinclair justly remarks, that no branch of husbandry requires such constant and unremitting attention. "If," says he, "a few spoonfuls of milk are left in the udder of the cow at milking; if any one of the implements used in the dairy be allowed to be tainted by neglect; if the dairy-house be kept dirty or out of order; if the milk is either too hot or too cold at coagulating; if too much or too little rennet is put into the milk; if the whey is not speedily taken off; if too much or too little salt is applied; if the butter is too slowly or too hastily churned, or if other minute attentions are neglected, the milk will be in a great measure lost. If these nice operations," continues Sir John, "occurred only once a month, or once a week, they might be easily guarded against, but as they require to be observed during every stage of the process, and almost every hour of the day, the most vigilant attention must be kept up throughout the whole season. That is not to be expected from hired servants."

Varieties of cows.

A proper choice of cows is of the greatest consequence, because certain species of this animal, as well as certain individuals of the same species, afford vastly more abundant and richer milk than others.

All the black cattle of the island have been divided into four classes. 1. The short-horned, or Dutch. 2. The long-horned, or Lancashire. 3. The polled, or Galloway. 4. The kyloes, or Highland. But in each of these classes there are many varieties.

The cows of the first class yield much milk; those of the second less, but its cream is more abundant and richer. The same quantity of the milk also yields a greater proportion of cheese. The polled or Galloway cows are excellent milkers, and their milk is rich. A sort called the Suffolk duns, said to be a variety of the Galloways, are much esteemed for the abundance of their milk, and the excellence of the butter it produces. Two-thirds of these, with one-third of the small Alderney or French cow, (mixing the milk,) are recommended by some as the best dairy stock that can be kept. Ayrshire, or Kyle cows, are much esteemed in Scotland; and in England the improved breed of the long-horned cattle, by Mr Bakewell of Dishly in Leicestershire, is highly prized in many dairy districts. The limits of this article will not permit us to mention a variety of other good breeds that might be pointed out. Every judicious selector, however, will always, in making his choice, keep in view not only the different sorts and individuals of the animal, but also the nature of the farm on which his cows are to be put, and the sort of manufactured produce he is anxious to bring to market.

Dairy.

The best age for a milk cow is betwixt four or five, and ten. When old she will give more milk, but it is of an inferior quality, and she is less easily supported.

Management of cows.

In the management of cows, two things are evidently of the greatest consequence,—to keep the animals easy, clean, and well aired; and to supply them with a sufficiency of wholesome nourishing food. It is quite certain, that if they be either over fatigued, immersed in dirt and nastiness, or deprived of the benefit of fresh air and proper food, they cannot enjoy good health; and as milk is a secretion from the animal system in its healthy state, whatever tends to impair this state must injure the secretion of the milk. When the cows are turned out to pasture, they must not be over-driven, or have so far to travel as to induce fatigue. In the house they must be carefully cleaned, and have an abundant supply of fresh air. Their food, in winter, may be of two kinds, either dry or green. Of dry food, hay and straw are almost the only kinds used; but hay is too expensive to be employed as a constant food, and even though it were not, an intermixture of green or soft food, such as turnips, cabbages, potatoes, carrots, cole and malt grains, would essentially contribute to the health of the animal; and the two most usual, and certainly the most profitable kinds of green food that can be used, are cabbage and turnips. Carrots or potatoes given once or twice a day, along with other sorts of green food, will be profitable; but no dairy cows will pay if fed solely on these. From one to two hundred pounds a day of cabbages or turnips will be consumed by a middle-sized cow; but 70 to 100 with straw, is supposed to be as much as her produce will pay for.

In summer, the best food for cows is certainly grass, and that produced by old pastures has been generally thought preferable, and often asserted to afford the richest milk. But Dr Anderson has no doubt that this is a popular error, and has often seen finer dairy products afforded by proper management, from cows fed on cut clover and rye-grass, than from such as have been kept on the finest old pastures. This part of the subject is more fully discussed under our article Butter.

Sufficient shelter from the heat of the day, and from the insects in summer, and from excessive cold or wet in winter, should of course be well attended to. Close confinement to the house, is by no means so prejudicial to the health of cows as has been often imagined. They are found to thrive equally well on stall-feeding as in the fields; but then it is essentially necessary to keep them very clean, and to comb and dress them; for if this be neglected, their legs will swell, and their health suffer.

Mr Curwen of Workington was the first who demonstrated, by actual extensive experiment, the utility of stall-feeding dairy cows. He combined steamed chaff and oil cake, with different sorts of green food, and found that, by giving a middle-sized cow two stones of green food and two of boiled chaff, with two pounds of ground oil cake and eight pounds of straw, the daily expence of her keep was only 5½d. The oil cake he found to be much more productive of milk when given with steamed chaff, than when employed without it. Varying their food from time to time, is found to be of much advantage to cows, and this may probably arise from the additional relish with which the animal eats, or from the superior excitement of a new stimulus on the different secretions.

The cows for a few weeks before calving, should have every night a little hay, or a somewhat greater allowance of green food; and on the day of calving, they should be kept in, and have warm water. For a fortnight after calving, they should have with their green food a little hay or chopped straw, with some ground or crushed oats.

The land necessary to maintain a cow may, we believe, at an average, be stated from two to three English acres, if we take into account the corn, hay, straw, and every thing else which the animal consumes. No one dairy maid can manage with propriety more than a dozen or fifteen cows.

Dairy farming in Scotland was till lately very much neglected; but there are now in that country some establishments of this sort on a very large scale. The county of Ayr was the first to set the example. But Sir John Sinclair, in his late *Account of the Scotch Systems of Husbandry*, states, that the dairy farms of Mr James Ralston, in Fineview, on the shore of Lochryan in Wigtonshire, are at present the largest concern of the kind in Scotland. He kept some time ago 120 milch cows, and is making arrangements for adding about 100 more to the number.

"They are divided," says Mr Smith, in his *Survey of Galloway*, "into lots of ten or twelve to each *byre* or cow-house, and a dairy-maid is appointed to every fifteen cows. She is allowed an assistant at milking, procured from a neighbouring village, at 1s. per week. To stimulate exertion, Mr Ralston gives a premium of two guineas to the dairy-maid who has most distinguished herself for management; and, to enable him to make a fair estimate of their comparative merits, they are appointed daily, in regular succession, to different lots of cows."

The cows are never fed out of doors till the grass has risen, to afford them a full bite. In dry and hot weather, they are housed, and fed on cut grass from six in the morning till six at night; when they are turned out to pasture for the other twelve hours. During bad weather, they are housed both night and day, and fed plentifully with turnips, potatoes, or other green food. Chaff, oats, and potatoes, are boiled for them after calving; and they are generally fed on rye-grass-hay during the latter part of the spring.

Mr Ralston says, that, about three years ago, every cow on his farm yielded annually her own weight of Dunlop cheese, which then sold at 14s. or 15s. per stone; and that he would not keep a cow that did not, in the course of the year, produce her own weight of cheese, and that would sell for the price of the cow. Sir John Sinclair states the net profit of a milk cow, in the neighbourhood of Edinburgh, at £23 per annum. Where the breeding system is followed, the profits of the dairy, in butter, cheese, and milk, are allowed to be very inconsiderable, and cannot, on an average, be estimated at more than about two guineas per cow annually, when the calves are reared. But, including the value of the calves themselves, when sold at the age of one year, the net profit of each cow may be stated at from L.8 to L.10.

The two grand dairy products are butter and cheese. Of the former we have given an account in another part of this work, under its proper title; and we now go on to observe, that

Cheese.

Cheese is a well-known article of food, prepared from milk, usually that of the cow. When allowed to stand till spontaneous acidity takes place, or when certain substances are added to milk, it coagulates and separates into two parts, a solid and a fluid. The solid is named curd, the fluid whey. When the curd is taken out of the whey, subjected to pressure, and afterwards dried for use, it constitutes cheese.

The coagulation of milk is effected by various sub-

Dairy.

stances; all the acids, several neutral salts, especially those that contain an excess of acid, alcohol, sugar, gum, the gastric juice of animals, and the juice of several vegetables. The caseous matter is also separated by mere heat, when this is applied to milk in contact with the air. For then a thin pellicle is soon formed upon the surface, which, when removed, is succeeded by another, and so on for a considerable time; till at last, when the pellicles cease any longer to be formed, the remaining fluid is thin and serous.

Parmentier and Deyeux ascertained, that the matter of these pellicles is perfectly identical with pure cheese; and that the contact of the air promotes its separation merely by some mechanical action; for it was separated equally well when the milk was heated in contact with oxygen, hydrogen, and carbonic acid gas.

Substance for coagulating milk.

But the substance usually employed in dairies to produce the coagulation of milk, is a preparation of the stomach of a young sucking calf, well cleaned, and soaked in brine. An infusion of this is called rennet, runnet, or steep. And as, in cheesemaking, it is of the utmost consequence to have rennet well prepared and good, we insert the following approved method of preparing it, as given by Mr Marshall in his *Rural Economy of Norfolk*. "Take a calf's bag, maw, or stomach; and, having taken out the curd contained therein, wash it clean, and salt it thoroughly, inside and out, leaving a white coat of salt over every part of it. Put it into an earthen jar, or other vessel, and let it stand three or four days; in which time, it will have formed the salt, and its own natural juice, into a pickle. Take it out of the jar, and hang it up for two or three days, to let the pickle drain from it; resalt it; place it again in a jar; cover it tight down with a paper, pierced with a large pin; and in this state let it remain till it be wanted for use. In this state it ought to be kept twelve months: it may, however, in case of necessity, be used a few days after it has received the second salting; but it will not be so strong as if kept a longer time. To prepare the rennet for use, take a handful of the leaves of sweet briar, the same quantity of the leaves of the dog-rose, and the like quantity of bramble leaves; boil them in a gallon of water, with three or four handfuls of salt, about a quarter of an hour; strain off the liquor, and, having let it stand until perfectly cool, put it into an earthen vessel, and add to it the maw prepared as above. To this is added a sound good lemon, stuck round with about a quarter of an ounce of cloves, which give the rennet an agreeable flavour.

Dairy. Method of making rennet.

The longer the bag remains in the liquor, the stronger of course will be the rennet. The quantity, therefore, requisite to turn a given quantity of milk, can only be ascertained by daily use and observation."

A sort of average may be something less than a wine half pint of good rennet to fifty gallons of milk. In Gloucestershire, they employ one third of a pint to coagulate the above quantity.

Marshall's experiments.

As it is well known that much depends both on the proportion of rennet and the temperature of the milk, we shall present our readers with the following tabular view of Mr Marshall's experiments on this subject.

Dates.	Gallons of Milk set.	Degrees of Heat when set.	Cups of Rennet applied.	Time of Coming.	Heat of the Whey.	Covered or Uncovered.	Quality of the Curd, &c.
1781. June 5.	23	96°	2, weak	1 hour	....	.....	Delicate and good.
6.	23	96	2	1	....	.....	Somewhat tough, probably from being burnt to the kettle in which it was heated.
7.	27	94	2	2	88°	.....	Very good.
8.	26	102	1	$2\frac{1}{2}$	88	.....	Very good.
9.	25	100	$1\frac{1}{2}$	$1\frac{1}{2}$	92	covered	Good, but somewhat tough, owing, perhaps, to its being kept too warm.
10.	25	96	2	$2\frac{1}{4}$	87	uncovered	Very tender.
11.	23	100	1+	3	87	uncovered	Uncommonly delicate.
12.	24	100	2	2	89	uncovered	Uncommonly tender.
13.	28	92	3	$1\frac{1}{2}$	86	covered with a coarse linen cloth	Very good, and of a fine colour.
14.	28	100	2	$1\frac{1}{4}$	94	uncovered	Somewhat harsh, but of a good colour.
15.	28	95	2	$1\frac{1}{2}$	89	covered after three-fourths of an hour	Very good and tender.
16.	30	103 to 96 by cold water	$2\frac{1}{2}$	1	94	close covered	Pretty good, but not sufficiently tender.
17.	28	97	$2\frac{1}{2}$	$1\frac{1}{2}$	...	covered, not close	Somewhat tough.
18.	30	95	$2\frac{1}{2}$	$1\frac{1}{2}$	92	covered	Pretty good.
19.	30	92	2	...	....	covered	Very good.
21.	30	98, lowered by cold water to 95	...	...	....	.....	Curd good, cheese spongy.
23. Even.	15, warm from the cow	92	$2\frac{1}{2}$, weak	$\frac{3}{4}$	88	closely covered	Very delicate and good.
25.	40, half skim	87	3	$\frac{3}{4}$	79	slightly covered	Remarkably good of *this* sort.

Dairy.

From the above table it appears, that curd of a good quality may be obtained from milk heated from 87 to 103 degrees of Fahrenheit, provided, as Mr Marshall observes, the rennet be so proportioned, that the time of coagulation be from three quarters of an hour to two hours and a half; and provided the milk be kept properly covered during the process of coagulation. "From these," continues he, "as well as from a variety of other observations which I made in the course of the summer, it appears to me, at present, that from 85 to 90 are the proper degrees of heat; and that from one to two hours is the proper time of coagulation; and that the milk ought to be covered, so as to lose, in the process, about five degrees of its original heat. Still, however, he confesses, that his observations and experiments have not been extensive enough to furnish a sufficient illustration of this very difficult subject. "Climate, season, weather, and pasture," he says, "may require that these bounds should sometimes be broken."

It would appear, from the experiments of the 7th, 8th, and 9th of June, that the quality of the curd arises as much, perhaps, from the heat of the milk when it *comes*, as from its heat when *set*; for the whey on the 9th was 4 degrees higher than that on the 8th, though the milk had been set to steep two degrees lower. Perhaps, too, a great deal depends on the curd being broken up at the critical minute, and not allowed to stand after it has come.

Mr Marshall, however, at a later period, viz. in 1788 (see his *Rural Economy of Gloucestershire*), tells us, that the following observations were accurately made by him; and the results, it must be confessed, vary considerably from those already stated; an additional proof that this process is still imperfectly understood, and that much is yet wanting to complete our knowledge of it.

"*Swindon*, Monday evening, (21st July 1788). Heat of the air in the dairy-room 60°; milk 87½°; uncovered; came in one hour 10 minutes; whey 85°; curd of a middle quality."

"*Deyhouse*, Tuesday evening. Air 63°; milk 88°; not covered; came in half an hour; 'too much rennet;' whey 86°; the curd not tender, but far from being of a bad quality."

"*Westleycot*, Wednesday morning. Air 60°; milk 86°; uncovered; came in three quarters of an hour; whey 84°; the curd of a good quality."

"*Shaw*, Wednesday evening. Air 62°; milk 87°; not covered; came in about an hour; whey 86° (quantity very great); the curd of a good quality."

"*Avon*, Thursday evening. Air 60°; milk 88°; closely covered with a thick woollen cloth, to make the top and the bottom come together; came in about an hour; whey 87°; the curd very good."

"*Foxham*, Friday evening. Air 60°; milk 91°; covered with a thin cloth; came in one hour; whey 89°! nevertheless, the curd delicately tender!!!"

When entire-milk has been coagulated by any of the above means, the coagulum afforded contains two substances; one of the nature of albumen, and the other of the nature of oil. The first is properly the cheese; the second, butter. But when cheese is prepared for the table, the butter is not separated, because it improves the taste of the cheese. The substances which coagulate milk have all been thought to act by means of the acid which they contain; but alcohol coagulates milk, and yet it contains no acid. Besides, Young, and more lately Parmentier and Deyeux, have shewn, that rennet retains its coagulating power, even when an excess of alkali is added to it.

Dairy.

Action of the vegetable acids upon milk.

The vegetable acids much diluted, are observed, when added to milk, to produce more curd than the mineral acids in the same state; and this is probably owing to the superior power which the latter have of redissolving the curd or cheese. For if one part of curd, newly separated, and not dried, be mixed with eight parts of water slightly acidulated by a mineral acid, and the mixture be boiled, the curd will be dissolved, though it would scarcely have been sensibly affected by a vegetable acid thus diluted. The vegetable acids, however, in their concentrated state, dissolve curd readily, and in considerable quantity; whereas the mineral acids, when concentrated, have either very little effect on it, as the sulphuric acid; or decompose it, as the nitric. By means of this last acid, a quantity of nitrogen may be obtained from curd.

The reason why neutral salts, gums, sugar, alcohol, and acids, coagulate milk, may be partly owing to the superior affinity of these bodies for water; but this subject is very little understood. If milk be diluted by ten times its weight of water, it cannot be coagulated at all; and the reason why heat alone is insufficient for its proper coagulation, is probably owing to the great dilution of the caseous matter in the serum of the milk itself. Scheele thinks the coagulation of milk, as well as of the white of eggs, and of the lymph or serum of the blood, is owing to the combination of caloric with these substances. The alkalies, in their caustic state, when aided by heat, dissolve cheese; and ammonia dissolves it more readily than potass or soda. A few drops of pure ammonia added to coagulated milk, quickly causes the curd to disappear. The fixed alkalies, in dissolving, decompose curd; for, during the solution, ammonia is disengaged; and, if the matter held in solution in the alkali be separated by an acid, it is found to be no longer curd, but a black fatty substance like oil.

Pure caseous matter is white, solid, somewhat elastic, insoluble in cold water, but, by boiling in water, its texture is destroyed. When fresh, it is nearly insipid, but becomes acrid on keeping. If left in a moist state of the air, it very soon putrefies; but if it has been thoroughly dried, it remains a long time unchanged. Good cheese melts at a moderate heat; but bad cheese, when heated, dries, curls, and exhibits all the phenomena of burning horn. Cheese must be admitted as a principle differing in some respects from all other animal matters. It seems most analogous to albumen, as it is soluble in a fluid resembling the serum of the blood, and as it is coagulated by heat. In several of its other properties, it is analogous to fibrin, and is probably intermediate betwixt these. It is the most animalized product of the milk, and is indubitably that which is most nutritious. When shaved thin, properly treated with hot water, and mixed with quicklime, it forms a very strong and durable cement.

If milk be much heated when it is put to coagulate, and if the curd be broken, and the whey suddenly and strongly pressed out, as is often the case in Scotland, the cheese is worth almost nothing, but the whey is excellent, and will afford much butter. But when the whey is separated by a slow and gentle pressure, the cheese is good, but the whey limpid and poor. Thomson's *Chemistry*.

Milk having been adopted by the human race as food at an early period of society, it could not be very long before they discovered the use of cheese: for milk, on being allowed to stand for any considerable time, spontaneously coagulates, and separates into curd and whey. This would naturally enough suggest the idea of attempting to detach, dry, and preserve the curd; and hence, not improbably, the origin of the manufacture of cheese.

Origin and history of cheese.

In the Book of Job (unquestionably the most ancient record in the world), mention is made of cheese. "Hast thou not poured me out as milk, and curdled me like cheese;" chap. x. 10. And, in the first Book of Samuel, chap. xvii. 18, when David, while yet a youth, was sent by his father Jesse to the camp in the valley of Elah, with refreshments for his brethren, "ten cheeses," we find, were thought a proper present to their commanding officer. "Carry these ten cheeses unto the captain of their thousand, and look how thy brethren fare." Cheese was also among the supplies furnished at an after period to the same David and his troops at Mahanaim, by Shobi, Machir, and Barzillai, during the war with his rebel son, Absalom; 2 Sam. chap. xvii. 29.

Cheese is mentioned by Homer, (B. C. 907.) It formed no small part, we perceive, of the ample stock of provisions found by Ulysses and his companions in the cave of the cyclops Polyphemus.

> Ἐλθόντες δ' ἔις ἄντρον ἐθηεύμεσθα ἕκαστα·
> Ταρσοὶ μὲν τυρῶν βρῖθον, στεινοντο δὲ σηκοὶ
> Ἀρνῶν ἠδ' ἐρίφων. *Odyss.* l. ix.

> Around the grot we gaze; and all we view,
> In order ranged, our admiration drew:
> The bending shelves, with loads of cheeses prest;
> The folded flocks, each separate from the rest.

Euripides (B. C. 407), Theocritus, and other early poets, also mention cheese.

Hippocrates, who lived in the fourth century before the Christian era, speaking of the ancient Scythians, tells us, that they shook the milk of their mares in wooden vessels; and that the heavy and thick part which subsides (when the fat part rises to the surface, and the thin or serous part remains in the middle), was by them kneaded and dried, and known by the name of *hippace*. It was esteemed an excellent article of food. No doubt this was cheese made of mares' milk. Probably, though Hippocrates does not mention it, they had a method of accelerating the process, by the addition of the juice of some plant, or other coagulating substance. In another place, he expressly mentions cheese (τυρος), and says, the Scythians made it of the milk of their mares, and employed it as food. Aristotle says, that milk consists of two parts, the watery and the *cheesy*, and gives us a good deal of accurate information respecting them both. But, in another place, he incidentally, as it were, mentions a fat substance also contained in milk, which, he says, in some cases resembles oil; by which, he no doubt means the butyraceous part of milk.

According to Ludolfus, excellent cheese, as well as butter, was made by the ancient Ethiopians. Cæsar, in his *Commentaries* (L. vi. c. 22), speaking of the ancient Germans, says, "*Agriculturæ non student, majorque pars victus eorum in lacte, caseo, carne consistit.*" Strabo, likewise, (L. iv.) mentions their living upon cheese; but Pliny (L. x.) says, that though they made butter, they were ignorant of the art of making cheese. Yet the oxygala, of which he speaks, was evidently a sort of cheese; and Columella has described the manner of its preparation. In making it, the milk was usually rendered sour, and the whey was pressed out. Pliny likewise says, that oxygala was prepared from the caseous parts of butter-milk, which remained behind after the butter had been separated. Strabo, speaking of the ancient Britons, tells us, that though they had abundance of milk, some of them were so ignorant, that they did not know how to make cheese. But when he says that some of them were thus ignorant, it evidently implies that he believed others of them to be possessed of the art. Tacitus (*Ger.* cap. 23.) informs us, that the food of the ancient Germans was simple, consisting of wild fruits, fresh venison, and concrete milk (*lac concretum*). But whether by *lac concretum* he means cheese or butter, or simply curdled milk, is not known. That cheese was a common species of food among the inhabitants of ancient Rome, we learn from the first Eclogue of Virgil, where the shepherd Tityrus, addressing his unfortunate neighbour Melibœus, thus expresses himself.

> Quamvis multa meis exiret victima septis
> Pinguis, et ingratæ premeretur caseus urbi,
> Non unquam gravis ære domum mihi dextra redibat.

And, in the same inimitable poem, whilst Melibœus is driving, in despair, his exiled flock from those grounds which had been long the property of his ancestors, he is told by his friend Tityrus that he might at least have spent one night more with him; and promised, if he would still do so, pressed milk (probably cheese) as part of the entertainment.

> Hic tamen hanc mecum poteras requiescere noctem
> Fronde super viridi. Sunt nobis mitia poma,
> Castaneæ molles, et pressi copia lactis.

In modern times, the use of cheese prevails, we believe, universally, wherever human society has advanced so far as to have reached the pastoral state. No traveller with whom we are acquainted states an exception to this rule. In Europe, certain countries, and certain districts of countries, are particularly noted for the manufacture of cheese. England, Holland, and Italy, are the most celebrated countries in this respect; and in England, Gloucestershire, Leicestershire, Wiltshire, and Cheshire; as in Italy, Parma, Piacenza and Lodi are famed for their cheese. In Scotland, too, Dunlop cheese has long been highly esteemed.

Different modes of manufacturing cheese.

Of the different modes of manufacturing the principal sorts of cheese, and of their comparative merits, we have now to give some account. But, first, it is to be observed, in general, that cheese varies in quality, according as it has been made of milk of one meal, of two meals, or of skimmed milk; and that the season of the year, the method of milking, the preparation of the rennet, the mode of coagulation, the breaking and gathering of the curd, the management of the cheese in the press, the method of salting, and the management of the cheese-room, are all objects of the highest importance to the cheese-manufacturer; and yet, notwithstanding this, the practice in most of these respects is still regulated by little else than mere chance and custom, without the direction of enlightened observation, or the aid of well-conducted experiment.

In Gloucestershire, where the manufacture of cheese is perhaps as well understood as in any part of the world, they make their best cheeses of a single meal of milk; and, when this is done in the best manner, the entire meal of milk is used, without any addition from

Dairy.

a former meal. But it not unfrequently happens that a portion of the milk is reserved, and set by to be skimmed for butter; and at the next milking this portion is added to the new milk, from which an equal quantity has been taken for a similar purpose. One meal cheeses are principally made here, and go by the name of *best making*, or simply *one meal* cheeses. In this county, cheeses are distinguished into *thin* and *thick*, or *single* and *double*. The last having usually four to the hundred weight, the other about twice that number.

Qualities and times of making Gloucester cheese.

Gloucester cheese is of a pleasant, mild taste, and very agreeable to almost every palate. Mr Hazard (4th vol. of the *Bath Papers*) says, that the best double Gloucester is always made from new milk, or (as it is termed by the people of this and the neighbouring counties,) "*covered milk*;" but that an inferior sort is made from what they call "half-covered milk;" and when any of these latter happen to be particularly good, they are sold by such as are not very scrupulous in their dealings, for the "best covered milk cheese;" "but honest farmers," continues he, "stamp them with a heart-shaped stamp, by which they are distinguished. The true single Gloucester cheese is thought by many to be the best in point of flavour of any we have. The season for making their thin or single cheese, is mostly from April to November; but the principal season for the thick or double, is confined to May, June, and the early part of July. This is the busy season in the dairy; for at an earlier period the milk is not rich enough; and if the cheeses be made later in the summer, they do not acquire sufficient firmness to be marketable next spring. Very good cheese, however, can be made even in winter, from cows that are well fed.

Attention requisite in milking the cows.

In this county, as well as in Wiltshire, and some others, they milk their cows in summer at a very early hour; generally by four o'clock in the morning, before the day becomes warm, and the animals restless and unruly. They are again milked in the evening about the same hour. Nothing requires greater attention than this operation, from every farmer who would profit by his dairy. It should never be confided to the management of common servants. The farmer himself, or some trusty person for him, should always superintend it. For if a cow be not properly milked, it is perfectly well known that her milk will not only be gradually diminished in quantity, but she will be in danger of going dry altogether; and moreover, become liable to diseases in consequence of the reabsorption of the milk. Besides, it has been proved, that the last drawn parts of the milk are vastly superior in quality to the first, and therefore ought not by any means to be lost.

One meal cheese.

When a one meal cheese is to be made, (and it will be for the interest of every farmer to make one if he has a sufficient number of cows,) the rennet is put to the milk in a large vessel called a cheese-tub, immediately on its being brought in warm from the cow. As soon as coagulation has taken place, the whey is carefully strained from the curd, and this is broken small and equally by the hand. It is then by little and little, (breaking it all the while,) put into a vat, a strong vessel commonly made of elm, and adapted to the size and form of the intended cheese. The vat is filled an inch or more above the brim. This is done to prevent the curd from shrinking below its sides when the whey is squeezed out; for if the curd should thus shrink, the force of the press being henceforth sustained by the brim of the vat, the cheese would be uninfluenced by it, and good for little. Previously, however, to the curds being put into the vat, a cheese-cloth or strainer is spread over it, and is so large as to be sufficient when turned up to envelope the whole cheese. A smooth round board, about an inch thick, is then laid on the vat, and the whole put into a press to remain for two hours. It is then taken out, and the cheese turned over. A clean dry cloth is substituted for the wet one, and the press is again applied for six or eight hours more. The cheese is now turned a second time, and rubbed on each side with salt. A dry cloth being again furnished as above, it is a third time put into the press, and allowed to remain for twelve or fourteen hours. At this period of the process, if any of the edges happen to project, they are paired off; and the cheese being laid upon a dry board, is regularly turned every day. To allow the escape of the whey, holes are generally made in the lower part of the vat; for it is quite necessary that every drop of the whey should be expelled.

Dairy.

Method of managing in the press.

Skewering.

When cheeses of a large size are made, iron skewers are thrust in various directions, through holes in the sides of the vat into the curd, to facilitate, when withdrawn, the escape of the whey; and this is done repeatedly during the first day of pressing.

Marshall's observations on vats and press.

Mr Marshall justly observes, that in every cheese dairy there should be vats of various sizes constantly in readiness. For if this be not the case, the dairy-maid will often be limited in her choice, and unable to adapt the vat or vats she employs to the quantity of curd she happens to have in her cheese-tub; and the addition of a little overplus curd, which has been kept from meal to meal, often spoils a whole cheese. Besides, when three or four cheeses are made at a meal, a number of vats come to be actually in use. He observes, with no less truth, that a great deal depends on the proper construction of the press and its power. "If," says he, "it does not press level, if it has too much play so as to incline or become tottering or leaning one way or another, and do not fall perpendicular upon the cheese-board, one side of a cheese will frequently be thicker than another; and what is still worse, one side will be thoroughly pressed, while the other is left soft and spongy." Its power may be given by a screw, by a lever, or by a dead weight, and ought to be proportioned to the thickness of the cheese. "I had one," says he, "constructed on the above principles, the power a dead weight of stones contained in a cubical box, moving in grooves, so as to keep its bottom horizontal, the medium weight 1 cwt. 2 qrs. but regulated by the stones agreeably to the thickness of the cheese or cheeses to be pressed."

Method of colouring cheese.

As most people have attached the idea of excellence to cheese of a high yellow or orange colour, the farmer, who would dispose of his cheese to advantage, is in a great measure necessitated to impart such to what he offers for sale. It is done by means of a preparation from the *Bixa orellana* of Linnæus, commonly called Spanish *annotto*. The red pulp, which covers the seeds, is suspended in hot water, allowed to subside, dried, and formed into cakes or balls. These are set aside to dry more completely, and become perfectly firm. An ounce of this substance, when genuine, is sufficient to colour a hundred weight of cheese; and this is the proportion usually employed in the county of Gloucester. They rub a piece of the annotto upon a smooth stone kept for the purpose, and then mix it thus levigated with the milk previously to applying the rennet. It adds nothing to the goodness of the cheese,

Dairy.

but being perfectly harmless, no bad consequences can arise from its use. The quantity employed is very generally judged of by the shade of colour to be imparted, without any very certain rule; and the degree of colour in most cases is adapted to the name under which the cheese is intended to be sold. In north Wiltshire, says Mr Marshall, a new species of prepared annotto has lately been discovered, which gives the milk and the curd a beautiful yellow hue.

Skimmed milk cheese is made only in those districts where butter is the chief object; and the milk is used after it has been two or three times skimmed.

Cheshire cheese.

In Cheshire, where they make cheeses of the largest size, (60 or 100 pounds,) they milk their cows in summer at six o'clock morning and evening; but in winter, at day-light in the morning, and just before dark in the evening. After the milk has been strained to free it from any impurities it may have caught during the milking, it is conveyed into a cooler placed upon feet like a table. This is a leaden cistern, nine inches deep, five feet long, and two and a half wide, with a cock or spigot at the bottom for drawing off the milk. This, when sufficiently cooled, is drawn off into pans, and the cooler again filled. In some cases the cooler is large enough to hold a whole meal's milk at once. The rapid cooling thus produced (which, however, is necessary only in hot weather and during the summer season,) is found to be of essential utility in retarding the process of fermentation, and thereby preventing ascescency from commencing in the milk before two meals of it can be put together. Some have thought that the cheese might be improved by cooling the evening's milk still more rapidly; and that this might be effected by repeatedly drawing it off from, and returning it into the cistern. When the milk is too cold, a portion of it is warmed over the fire and mixed with the rest.

Milking and cooling the milk.

Meals of milk to a cheese.

A cheese in this county is seldom made of one meal. And even when two cheeses are made in the day, (that is, one in the morning and another in the evening,) two meals of milk are generally put together. Nay, in the beginning and end of the season, when the cows do not afford so large a quantity, or when there are fewer of them in milk, even three, four, or sometimes five or six meals are employed in making one cheese. Now, as the goodness of cheese depends greatly on the quantity of cream left in the milk, and as cream necessarily separates from milk on being allowed to stand, it has been doubted by some, whether cream, once separated, can be again so intimately united with milk, as not to undergo decomposition in the after process of making cheese. From some idea of this sort, it has become customary to withdraw a part of the cream from the evening's milk, when a two-meal cheese is to be made in the morning. But the best farmers condemn this practice, reunite the whole cream to the milk, and believe that when thus again blended, the mixture differs in no respect from new milk, in as far as cheese-making is concerned. The test of experiment, however, is necessary to decide this point. If a cheese, made in the morning wholly of the night's milk, on which the cream had risen, be found to be as rich and good as one made of new milk, all the other circumstances being the same, we shall have a proof that milk and cream after being separated, may be again so united as to become the same as new milk. All agree, that in making a one meal cheese of the best quality, no part of the cream should be abstracted. The cheese is sometimes made in the evening, but most frequently in the morning. When two meals of milk are used, unless the weather be very hot, a portion of the creamed milk of the former meal, as a half, a third, or more frequently only three or four gallons are reserved, and being placed in a brass pan over a furnace, or in a vessel of hot water, is made scalding hot. Half of it is then poured into the cheese tub among the cold milk, and the remainder into the pan in which the cream of this same milk had been placed. The hot milk and cream being now intimately mixed, are poured into the cheese tub, and the warm milk added that had just come in from the cow. This is called *melting the cream*, and is thought to be the best method known of uniting two or more meals of milk. The rennet is now applied. In making cheeses of the inferior kind, as from skimmed milk, where, from its tendency to acidity, there is a risk that it will break or curdle while over the fire, the whole is brought to a proper temperature by the addition of hot water.

Dairy.

Colouring

The colouring matter (annotto) in Cheshire, is added by tying up as much of the substance as is thought sufficient in a linen rag, and putting it into a half pint of warm water to stand over night. The whole of this infusion is, in the morning, mixed with the milk in the cheese tub, and the rag dipped in the milk and rubbed on the palm of the hand as long as any of the colouring matter can be made to come away.

Temperature on coagulation.

The temperature of the milk when coagulating, we have already shewn to be of the greatest consequence; and yet in this point there are scarcely two dairies whose practice is the same. In those of Cheshire it is commonly estimated that the lowest degree of heat which the milk ought to have when the steep is put to it, is one half of what it has when newly drawn from the cow; and the highest about twice the natural warmth. It is thence concluded, that when a one meal cheese is to be made, no great error will be committed, if by the time a large dairy of cows has been milked, and the milk deposited in the tub for coagulation, the rennet be immediately applied. But this, it must be evident, is a very uncertain rule, seeing it is liable to be influenced by the season of the year, the state of the weather, and the time employed in milking. Universally, therefore, in all dairies where cheese of a superior quality is produced, the milk is coagulated at a fixed degree of heat; that, namely, which has been found by experience to be the best. Mr Rudge is of opinion, that the average temperature necessary to be observed, may be betwixt blood and summer heat, or 90° of Fahrenheit. But the experiments of Mr Marshall, formerly stated, seem to be the most satisfactory on this subject. It is found, however, that milk produced on poor clays requires to be coagulated at a higher temperature than that which is produced from rich pastures. Something, therefore, it would appear, does depend upon the pasture in cheese-making as well as in the making of butter, though not nearly so much, we know, as on management in both these operations.

Gathering the curd.

As soon as coagulation has taken place, the curd is broken and gathered. Various methods of doing this prevail. The following seems to be judicious. A cheese knife is employed to cut the curd in various directions, and this being allowed to subside for a short time, is again cut by the knife more freely than before, and the operation continued till the whole be reduced to small uniform particles. This business may occupy about the space of forty minutes; after which the cheese tub is again covered with a cloth, and allowed to remain for nearly the same time. When the particles have subsided, the whey is laded off, and the curd properly pressed, by the bottom of the skimming dish, the hands,

Dairy.

or a semicircular board and weight, adapted to the size of the tub. The cheese knife is now employed as before to cut or pare the curd, thereby promoting the free separation of the whey; and pressure is again applied till it be all drained off. The curd is then put into two or three separate vessels, and the dairy-maid and her assistant break it with their hands as small as possible. During this part of the process, salt is scattered over the curd, and intimately mixed with it. The proportion of salt is not well ascertained, and is regulated merely by estimation.

Breaking and vatting.

Sometimes the skimming dish and hand only are used in breaking the curd, particularly when the milk has been set to steep rather cool, and the curd is of course tender. When it has been properly broken and salted, it is collected into the cheese vat; and this is done in the same manner as formerly described. When turned in the vat previously to its being put into the press, it is rinsed with warm whey, and wrapped in a finer cloth; pains being taken to put the edges of the cloth completely within the vat, so as perfectly to inclose the whole cheese.

Binding, filleting, and managing in the press.

To prevent squeezing over the sides of the vat when the press is let down, a hoop or binder of tin or white-iron, about three inches in breadth, is put round the cheese, and the lower edge of it placed within the brim of the vat. Sometimes cheese fillets of a coarse sort of strong broad tape are used instead of the tin binders. One end of the fillet is thrust down with a wooden knife betwixt the cheese cloth and vat, and then drawn tightly several times round the cheese and fastened with strong pins. The operation of skewering commonly continues till the morning after the cheese has been put in the press, and the oftener it is turned and shifted during that interval the better. Seldom is it allowed to remain more than half an hour, never above two or three hours after its being first put to the press till it be again taken out. The cheese or cheesling is now placed without its cloth in a vessel of hot whey or water, to stand for an hour or two. This is to harden its skin and prevent blistering. It is then wiped dry, and covered with a clean dry cloth; again placed in the vat (which is also wiped dry), and put under the press. Sometimes to allow the escape of extricated air, and prevent blistering, the upper surface of the cheese at the two first turnings is pricked all over with a small bodkin an inch or two deep. It is taken out, wrapped in a clean dry cloth, and replaced in the vat twice a day at least, during two days, when it is finally removed. In the two last turnings, cloths of a finer texture are employed, that no mark of them may remain on the cheese. Some think it necessary to bare-vat the cheese, in order that every mark of the cloth may be effaced.

Salting.

The next operation is salting; and this is done, either by laying the cheese immediately after it comes out of the press on a clean fine cloth in the vat, immersed in brine, to remain for several days, turning it once every day at least; or by covering the upper surface of the cheese with salt every time it is turned, and repeating the application for three days successively, taking care to change the cloth twice during the time. In each of these methods, the cheese, after being so treated, is taken out of the vat, placed upon the *salting-bench*, and the whole surface of it carefully rubbed with salt daily for eight or ten days. If it be large, a wooden hoop or a fillet of cloth is employed to prevent renting. The cheese is then washed in warm water or whey, dried with a cloth, and laid on what is called the *drying-bench*. It remains there for about a week, and is thence removed to the keeping-house. In Cheshire, it is found that the greatest quantity of salt used for a cheese of sixty pounds is about three pounds; but the proportion of this retained in the cheese has not been determined.

Management in the store-house.

When after salting and drying, the cheeses are deposited in the cheese-room or store-house, they are smeared all over with fresh butter, and placed on shelves fitted to the purpose, or on the floor. During the first ten or fifteen days, smart rubbing is daily employed, and the smearing with butter repeated. As long, however, as they are kept, they should be every day turned; and the usual practice is to rub them three times a week in summer and twice in winter.

The cheese-rooms in Cheshire are generally placed over the cow-houses. This is done to afford them, from the heat of the cattle below, that uniform and moderate degree of temperature which is supposed to be essential to the proper ripening of the cheese. Dry coarse grass or rushes are placed as litter on the floor.

Mr Marshall's method.

Such are the most approved methods in the principal cheese districts. But others are also practised. The method detailed by Mr Marshall in his *Rural Economy of Norfolk*, as the one which he himself followed, appears to us so good, that we deem it right to lay it before our readers. "The practice," says he, "in my dairy, has been uniformly this: As soon as the curd is come at the top firm enough to discharge its whey, the dairy woman tucks up her sleeves, plunges her hands to to the bottom of the vessel, and, with a wooden dish, stirs the curd and whey briskly about; she then lets go the dish, and by a circular motion of her hands and arms, violently agitates the whole; carefully breaking every part of the curd; and at intervals, stirs it hard to the bottom with the dish, so that not a piece of curd remains unbroken larger than a hazel nut. This is done to prevent what is called *slip-curd*, (that is, lumps of curd which have slipped unbroken through the dairy woman's hands,) which, by retaining its whey, does not press uniformly with the other curd, but in a few days (if it happen to be situated toward the rind,) turns livid and jelly-like, and soon becomes faulty and rotten. This operation takes about five or ten minutes; or, if the quantity of curd be large, a quarter of an hour.

"In a few minutes the curd subsides, leaving the whey clear upon the top. The dairy woman now takes her dish, and lades off the whey into a pail, which she empties into a milk-lead to stand for cream, to be churned for whey butter; a practice peculiar to the cheese counties, and which forms no inconsiderable part of the profit of a dairy in those counties.

"Having laded off all the whey she can, without gathering up the small pieces of loose curd floating near the bottom of the vessel, she spreads a straining cloth over the cheese tongs, and strains the whey through it, returning the curd retained in the cloth into the cheese-tub. When she has got all the whey she can, by pressing the curd with her hand and the lading-dish, she takes a knife and cuts it into square pieces, about two or three inches square. This lets out more of the whey, and makes the curd handy to be taken up, in order to be broken into the vats.

"Having made choice of a vat or vats proportioned to the quantity of curd, so that the cheese when fully pressed, shall neither over nor under fill the vat, she spreads a cheese-cloth over the vat, into which she rebreaks the curd, carefully squeezing every part of it with her hands; and having filled the vat heaped up and rounded above its top, folds over the cloth, and places it in the press."

Scalding.

In autumn when the weather got cool and moist, the curd was *scalded*, "to make the cheese come quicker to hand," (that is, sooner saleable,) and to prevent a white woolly coat from rising. It is done thus: If the cheese be made from new milk, scalding water (boiling water with a small quantity of cold whey mixed with it,) is poured over the whole surface of the curd as it lies at the bottom of the cheese tub. *—If from skimmed or other inferior milk, the outsides only are scalded, after the curd is in the vat, by first pouring the scalding water on one side, and then, turning the cheesling, pouring it on the other." "Supposing," says Mr Marshall, "the cheesling to be made on Monday morning at seven o'clock, it is between eight and nine taken out of the vat, the cloth washed, and immediately placed in the press again. On Monday evening it is salted, and, if wanted, pared; put into a dry cloth, and replaced in the press. On Tuesday morning, it is bare-vatted, or the cloth changed; the cheesling in either case being turned, and again put into the press. On Tuesday evening it is again turned; and on Wednesday morning finally taken out of the vat and press."

Production of the *blue coat* in cheese.

As soon as the cheeses become firm enough to be handled with safety, he causes them to be well brushed with a hard brush frequently dipped in whey; and when nearly dry, rubbed over with a cloth on which fresh butter had been spread. He has them thus washed, scraped, rubbed, and turned once a-day for some weeks, "till they acquire a rich golden polish, and the *blue coat* begin to shew itself." This will be regulated not only by the age of the cheese, but by its quality, and the state of the weather, therefore no certain number of cleanings can be fixed; and the *blue coat* will appear perhaps before one month, perhaps not till the end of two or even three. The cheeses, however, ought to be regularly scraped and rubbed until they be perfectly smooth, and the rind mellowed with butter, whenever it gets dry and harsh. The blue coat is that desirable appearance of a cheese, which is at once a criterion of its goodness, and of the skilfulness of the dairymaid.

Method of making Parmesan cheese.

The Italian cheese called Parmesan, so highly prized, is, according to Mr Benjamin Pryce and Mr Arthur Young, who observed the operation on the spot, made entirely of skimmed milk, and the process conducted as follows. Two meals, the evening's after it had stood sixteen hours, and the morning's about six, were put together. At ten o'clock, this milk, consisting of about 264 English quarts, was suspended in a large copper, by a crane over a slow wooden fire. When an hour had nearly elapsed, the milk, having been frequently stirred, was about 82° of Fahrenheit, and the heat of the atmosphere at the time was 70°. The cazaro, or dairyman, took a ball of rennet like a large walnut, and squeezed it through a cloth into the milk, which was all the while stirred. He then removed the copper from off the fire by means of the crane, and a few minutes past twelve the rennet had operated. The coagulated milk was freely stirred up, and allowed to stand for a little till the whey should in some degree separate. At one, the cazaro ordered his sotto-cazaro to work the curd, which he did with a stick properly armed with cross wires. The curd being reduced to a small grain, and left to subside till the whey was nearly clear on the surface; part of this was taken out, and the copper again turned over the fire. It was now brought to a heat somewhat below boiling, and a quarter of an ounce of saffron added, to impart a slight degree of colour. All this while, the curd was stirred with a wooden instrument, to prevent singeing or burning; and the cazaro from time to time examined it betwixt his finger and his thumb, to mark the exact moment when it should have attained sufficient firmness and solidity. The heat was $124\frac{1}{2}$ of Fahrenheit. It is, however, often raised considerably higher.

When the small grains of curd felt as firm as the cazaro wished, (which was in about an hour and a half,) the copper was taken from the fire, and the curd allowed to subside. The cazaro then drew off about three-fourths of the whey; poured round the bottom of the copper three or four gallons of cold water, to cool it so far as that he might be able to handle the curd, and slid below this a cloth, by which he brought it up and placed it in a tub to clear. When drained, it was put into a hoop, and about half a hundred weight laid upon it for an hour. The cloth was then removed, and the cheese placed again in the hoop, and put upon a shelf.

Their practice is to allow it to remain there for two days, at the end of which period it is sprinkled all over with salt: and this is repeated every two days, for thirty days successively if it be summer, and forty if it be winter; after which no farther attention is requisite. During the process of salting, they place two cheeses on one another, in which situation they are supposed to take the salt better than when single. They are afterwards scraped clean, turned in the magazine once every day, and rubbed with linseed oil, to preserve them from insects. They are never sold till they have been kept six months.

Parmesan of ewe's milk.

After the cheese has been made as before described, the morning's butter-milk is added to the whey, a fresh coagulation produced by means of an acid, and a sort of cheese made called Maschopino. At Rochefort in Languedoc, they make Parmesan of ewe's milk; and in other places it is usual to add a certain portion of ewe's or goat's milk to that of the cow.

Stilton cheese.

Stilton cheese is made by putting the night's cream into the morning's new milk along with the rennet. When the curd is come, it is not broken as in making other cheese, but taken out whole and put into a sieve to drain gradually. Whilst this is going on, it is gently pressed; and having become firm and dry, is put into a vat, and kept on a dry board. These cheeses are exceedingly rich and valuable. They are called the Parmesan of England, and weigh from six to twelve pounds. Their most usual name is *cream cheeses*. The manufacture of them is confined almost exclusively to Leicestershire, though not entirely so.

Many persons in Huntingdonshire, Rutland, and Northamptonshire, make cheeses of the same sort, and sell them for Stilton cheeses. Stilton, every body knows, is only a place of sale, no cheeses being made within many miles of it. Some make them in a net like a cabbage-net, and give them the form of an acorn. They are not sufficiently mellowed for use, till two years of age; and will not sell unless decayed, blue, and moist. In order to hasten their maturity, it is a common trick to place them in buckets, and cover these over with horse dung. Wine added to the curd brings on a rapid advance of ripeness in cheese. As the thinner cream cheeses are named Stilton, so there is a thicker sort called Cottenham cheese. Of late, attempts have been made to follow a French fashion regarding these cheeses.

Attempts to imitate French cheeses.

* The curd will be more equally affected by the scalding fluid by throwing that when broken into the fluid, than by pouring the fluid upon the curd. Scalding is done with the fluid from 102° to 140° and 192°.

Dairy.

In France it is common to mix particular plants and herbs in their cheeses. Now we have likewise in this country cheeses *aux fines herbes, à l'Estragon, au Capucin*, &c.

Lincolnshire cheese.

In Lincolnshire, they make a rich and excellent cream cheese, by adding the cream of a former meal of milk to that which comes immediately from the cow. The cheese is gently pressed only two or three times; and when but a few days old, is sold to be eaten with radishes, sallad, and the like.

Green cheese.

Green cheese is made by steeping over night in a proper quantity of milk, two parts of sage with one of marigold leaves, and a little parsley after being bruised, and then mixing the curd of the milk thus *greened*, as it is called, with the curd of the white milk. These may be mixed irregularly or fancifully, according to the pleasure of the operator. The management in other respects is the same as for common cheese. These are mostly made in Wiltshire.

Dunlop cheese.

In Scotland, a species of cheese is produced, which has been long known and celebrated under the name of Dunlop cheese. The appellation is derived from a parish of the same name in Ayrshire, where this cheese was first made; but its manufacture is at present by no means confined to Dunlop. Many of the neighbouring parishes now make cheese equally good, and in far greater quantity. Indeed, when once the cheese from any part of the county is carried to a distance, it is called Dunlop cheese.

When introduced.

Making of cheese from unskimmed milk, or as it is termed, *sweet milk*, seems hardly to have been known in Scotland before the revolution. It was about this time, that a woman of the name of Barbara Gilmour, who had fled to Ireland from religious persecution, returned to Dunlop, and introduced the above manufacture. Her great-grandson is still living, and possesses the same farm.

Dunlop cows.

In this district, their cows are of a small rather than a large size; from 30 to 50 stone live weight. Particular attention is paid to their breed; and being fed in inclosures, they are never under a roof, except it be for milking, from May to October. Existing thus in the open air during all the mild part of the year, the animals probably enjoy the best health, and their milk is of the finest quality. They also afford it in large quantity, and are milked twice a-day, viz. at six, morning and evening. Some of them for two or three months after calving, have produced from 18 to 20 Scotch pints of milk per day, that is, from 9 to 10 English gallons; but this is rare, and the milk of such cows is usually thin and serous.

Method of making Dunlop cheese.

The best cheese is made by such as have a dozen or more cows, and consequently can make a cheese every day; one half of the milk being immediately from the cow, and the other of twelve hours standing. Their method of making it is simple, They endeavour to have the milk as near as may be to the heat of new milk when they apply the rennet, and whenever coagulation has taken place, (which is generally in ten or twelve minutes,) they stir the curd gently, and the whey beginning to separate, is taken off as it gathers, till the curd be pretty solid. When this happens, they put it into a drainer with holes, and apply a weight. As soon as this has had its proper effect, the curd is put back again into the cheese tub, and by means of a sort of knife with three or four blades, cut into very small pieces, salted, and carefully mixed by the hand. It is now placed in the vat, *chessel*, or *cheesitt*, as it is named in Scotland, and put under the press. This is commonly a large stone of a cubical shape, from half a ton to a ton in weight, fixed in a frame of wood, and raised and lowered by an iron screw. The cheese is frequently taken out, and the cloth changed; and as soon as it has been ascertained that no more whey remains, it is removed from the chessel altogether, and placed on a dry board or deal floor. It is turned and rubbed frequently with a hard coarse cloth, to prevent moulding, or breeding mites. No colouring matter is used in making Dunlop cheese, except by such as wish to imitate the English cheese.

Cheese in different parts of Scotland.

Excellent cheese, little if at all inferior to Dunlop, or even to some of the best English manufacture, has lately been made in Dumfries-shire, and some of the other southern counties of Scotland. A very good kind of plain cheese has been made on a farm near Thurso, in the north of Scotland, for a few years past; and in a particular district of Ross-shire, good cheeses are made, but not for sale. They have a singular mode of improving them, by burying the cheeses separately for some time within high-water mark. This makes them become blue, moist, and rich tasted, like Stilton.

Size of Dunlop cheeses.

The usual size of Dunlop cheeses is from 20 to 60 pounds; and a dozen good cows, well fed and managed, will produce in a season from 150 to 160 stones (provincial weight), that is, more than a ton and a half. This, when brought to market, at the rate of 10 to 12 shillings per stone, may produce from 70 to nearly 100 pounds sterling.

Defects of cheese.

Cheeses in general are liable to crack, to acquire rankness and pungency, to heave, to blister, and to run out at the sides. The first has been thought to arise from too suddenly exposing them to a current of air on their being taken out of the press. Rankness and pungency are commonly attributed to impure rennet, or to a deficiency of salt; but it is more probably owing to the imperfect separation of the whey. Heaving and running out at the sides, are properly attributed to the same cause, though some ascribe them to the rankness of certain pastures, or an improper temperature of the cheese house.

Remedies.

The usual remedy for blisters, is to cut them open and pour hot water into the incisions; then to press down the outer rind, putting on a little salt and a piece of slate loaded with a ten or twelve ounce weight. To prevent sponginess, or whey-spring in cheese, careful breaking of the curd, frequent skewering, and powerful pressing, are esteemed the best means. It is observed, however, that often from the same curd, a net cheese which has been scarcely pressed at all will be quite close, when one that has been strongly pressed will heave. This may not be easily accounted for; but certainly it appears to us, that a great error is committed in the usual method of pressing cheese. Holes, it is true, are generally made in the lower parts of the vat, to admit the escape of the whey; but as soon as the curd has been put in, the whole force of the press is applied at once; and the consequence is, that the curd is so strongly forced into the holes, that these are altogether plugged up, and might as well have never been made. The power of the press ought to be applied gradually. A screw might be the best method of effecting this; but even by means of a lever it could be very easily accomplished. We have only to suspend a weight on the lever at a proper distance from the fulcrum, so as to counteract, as far as may be thought necessary, the weight of the body employed as a press, and by moving gradually the counteracting weight nearer and nearer to the fulcrum, or point of support of the lever, the pressure would be thus slowly laid on.

Observations on pressing.

Dairy.

Cheese from the milk of different animals.

The ewe.

Though cheese be generally made from the milk of the cow, yet there are other animals from whose milk it can, and indeed frequently is procured. The Scotch make cheese from the milk of the ewe, and it is in considerable esteem for its rich, sharp, agreeable, flavour. The curd of ewe's milk has a fat viscid appearance, and is not so easily brought to assume a firm consistence as the curd of cow's milk.

It would appear that the practice of milking ewes, though still followed in many parts of Scotland, was much more prevalent there formerly than it is at present. Few customs are oftener alluded to in all the old pastoral ballads and songs of the country. The allusions to it in the "Gentle Shepherd," are well known, and in the beautiful ballads of "The Flowers of the Forest," and "Ewe bughts, Marion."

Allusions to ewe milking.

The goat.

Goats' milk, when the cream is separated, coagulates with the same facility as cows' milk, and yields a larger proportion of curd. It makes very excellent high-flavoured cheese, of a meagre appearance, but delicate relish; it resembles Parmesan. Frequently a portion of ewes' or goats' milk is added to the cows' milk, and is thought by many to improve the cheese very much. Mares' milk, when creamed, coagulates precisely as cows' milk, but the curd is not so abundant: The Tartars make cheese of it. From asses' milk, alcohol and acids separate a small proportion of curd, which has but little consistence, and could not be easily made into cheese.

The mare.

The ass.

Woman's milk.

Womans' milk cannot be coagulated by any of the methods employed in coagulating the milk of the cow; yet there can be no doubt that it contains curd; for if it be boiled, pellicles form on its surface, which have all the properties of curd; and it evidently coagulates in the stomachs of infants, as appears from what they occasionally eject by vomiting. Probably the cause of its not coagulating in the usual way, is the great quantity of water with which it is diluted.

Rein-deer.

The Laplanders make both butter and cheese of the milk of the rein-deer.

Not only does the milk of one genus of animal differ from that of another; but the milk of different varieties, and individuals of the same species, is found to be very different. The variety, or breed of the cow, therefore, which we employ on a cheese farm, is of much consequence; and every judicious farmer will take care to have that sort of cow which experience has shewn to be the best. In selecting or rearing his cow stock, he will have regard not only to the quantity and quality of the milk they afford, but to a third circumstance, namely, the fitness of the animal in point of hardiness for the situation in which it is to be placed. In this last respect the long-horned breed are much better than the short-horned, and most of the Scotch kinds are probably superior to either. The Alderney cow is highly esteemed. From the milk of this sort, Mr Marshall made cheese of a texture almost as close and firm as bees-wax, and nearly as high coloured. They were as different in quality and appearance from the produce of the long-horned cow, as if they had been a distinct species of animals. Individual cows also, of the same kind or variety, differ greatly in the quality no less than the quantity of their milk.

Varieties of milk.

Of cows.

The average quantity in the principal cheese districts may be stated at eight to twelve quarts a day; but this must obviously vary according to the mode of feeding and treatment, even in the same animal. Many cows will give twice the quantity above stated for a short period; but then they either soon go off their milk, or it has less richness than that of others.

Dairy.

Average quantity of milk from a cow.

Influence of pasture.

Pasture has also been thought to have great influence on the quality of milk, and consequently on the cheese made from it. It is commonly believed that old lands, that is, such as have been long out of tillage, produce milk which gives the best and the largest quantity of butter, and that such as have been more recently laid down in grass are the best for cheese. "The same cow," says Mr Rudge, in his *Survey of Gloucestershire*, "on two pastures, separated only by a hedge, will give milk of different qualities; from one shall be made fine rich and close cheese, while from the other shall be made rank, heaving, hollow cheese, unpleasant to the palate, and unfit for the market." He tells us, that in the parish of Haresfield, two grounds adjoining each other were used alternately for the pasture of some cows; and that while they were on the one, excellent cheese was made from them, but, on the other, it was difficult to make any that was tolerably good. The one was old pasture, and the other had been lately dressed with manure, and under tillage.

Noxious plants.

It is perfectly conceivable that there may be plants which thrive in new pastures, but disappear in the old; and we know that there are plants which, when eaten by the cows, greatly affect the nature of their milk. Wild garlic, for example, and the *brassica rapa*, or common turnip, give a disagreeable flavour to both butter and cheese; * and there may be many others, which, though not so palpable in their effects, are also noxious. White clover, (*trifolium repens*,) and almost all the species of crow-foot, (*ranunculus*,) are thought to be of this sort. But though we allow to certain pastures some effect in determining the quality as well as the quantity of the milk, still we are fully persuaded that far more depends on the management of the operator, than on this circumstance, in the production of good cheese. This is the opinion of the acute and experienced Dr Anderson, and we have had ourselves such opportunities of observing the effects of different sorts of management, that we have no doubt whatever of the justness of his sentiments. He well remarks, that mankind are always ready to lay the blame of failure on any thing rather than their own misconduct.

Cleanliness.

Of all the parts of dairy management, cleanliness is the most indispensible. "It is indeed," says Mr Donaldson, "not only necessary in dairy-husbandry, but the very foundation of it. A farmer may be in possession of the most valuable breed of cows, and these be fed in the richest pastures; but unless cleanliness prevail in the dairy, his butter or his cheese will never stand high in general estimation." Cleanliness chiefly consists in regularly scalding, scrubbing, rinsing, and drying the floors, shelves, and different implements used, so as to prevent acidity.

Quantity of cheese from a cow.

The quantity of cheese produced from a given number of cows, is differently stated in different districts. Some think $2\frac{1}{2}$ cwt. from each cow, a good average annual return. Others vary the estimate from this to 4 cwt. Mr Rudge, in his *Agricultural Report of Gloucestershire*, states the annual produce of each cow at $3\frac{1}{2}$ to $4\frac{1}{2}$ cwt. The annual produce of a dairy

* It is now we believe ascertained, and pretty generally known, that a small quantity of saltpetre, added to the milk while warm from the cow, entirely removes the disagreeable flavour arising from the use of turnip.

Dairy.

of 20 cows he calculates at L. 136, 10s. allowing 4 cwt. from each cow. He is of opinion that the profits of a well managed dairy may arise, in a considerable degree, from the feeding of hogs; but when these are not kept, the whey, he says, is valued and sold at L. 2 annually for each cow.

Quantity of cheese made in Berkley vale.

The actual quantity of cheese made in any particular district is not easily ascertained with accuracy. Marshall estimates the produce of the Vale of Berkley at about 1100 tons annually; and he says that, in 1788, at Barton fair, (the great yearly market for cheese, held on the 28th of September in Barton-street, Gloucester,) there were 40 waggon loads of cheese. The prices, however, he remarks, were almost 25 per cent. lower than they had been known to be for many years before, cheese being then a drug. The worst *two meal* cheese sold at a guinea, and the best *one meal*, at 30s. He mentions one factor, or copartnership of factors, who were said to send seven or eight hundred tons every year to the London market.

The Gloucestershire *one meal* cheese is principally bought by cheese factors, who live in and near the district, and sent to the London market; and the *two meal* cheese is consumed chiefly in the manufacturing districts of this and other counties. It sells about ten shillings a hundred weight cheaper than the other. Some of it goes to the London market, and is there probably sold under the name of Warwickshire cheese; an appellation often given to cheese which is in fact the produce of several counties. The cheese is bought by the factors from six weeks old and upwards.

Species made in Britain.

Many species of cheese are produced in this island; but our markets are filled chiefly by two sorts; the one of a dry loose texture, and of a rough austere flavour; the other of a texture close and wax-like, and milder to the taste. The former is sold under the name of Cheshire cheese, and is, we believe, chiefly the produce of that county and of Lancashire; the latter under the name of Gloucestershire cheese, provided its quality entitle it to that distinction; if not, it generally takes the name of Warwickshire cheese. Indeed the county of Gloucester could not produce one fourth part of the cheese usually sold under this name. The number of Cheshire cheeses has greatly decreased within the last ten years.

The products of Somersetshire, Wiltshire, Berkshire, Oxfordshire, Gloucestershire, Worcestershire, Warwickshire, Leicestershire, Staffordshire, Derbyshire, Durham, and Yorkshire, are very similar: all of them as different from the produce of Cheshire as if they were manufactured from a different material.

It is this milder species which is a principal article of food of various classes of working people. Gloucestershire has long had a decided superiority in the manufacture of it; but North Wiltshire is now a competitor, and bids fair to take the lead.

Chedder cheese.

The vale of Chedder, in Somersetshire, is thought by many to produce a species of cheese superior in quality to either, and to be therefore the best in England. Its quantity is very limited. It has a spongy appearance, and the *eyes* are filled with a rich limpid oil, not rancid. The true kind is nearly as thick as Cheshire, and they weigh about 30 lb. each.

The county of Durham produces many good cheeses. They are shipped at Stockton, where the cheese factors collect them as well as from Yorkshire, and are distinguished by the names of *new* and *old milk*.

Fanciful cheeses.

Almost all those little cheeses called truckles or loaves, brick-bats, hares, rabbits, pines, dolphins, &c. are made in Wiltshire, and their consumption increases every day. They were once tried on the farms of Harperland and Fairfield in Ayrshire, and succeeded very well: but being more troublesome to make than the common cheeses, and the farmer having no great anxiety to introduce a novelty, they were given up after two years successful experience.

Foreign cheeses. Swiss.

At Neufchatel in Switzerland, a very fine sort of cheese is made, greatly resembling a wash-hand ball: and in the district of Gruyere, a small town in the canton of Fribourg, the famous large cheeses are made which go by that name. Gouda cheese is famous in Holland, and was much esteemed here, while it was to be procured; but during the long interruption of our intercourse with that country was very seldom to be seen. We may now, however, hope to obtain it.

Dutch.

French.

In France, many districts are noted for the excellency of their cheese. "Roqueforte cheese," say the authors of the *Encyclopedie*, "is doubtless the best in Europe. That of Brie, Sassenage, of Marolles, yields in no respect to the best foreign cheese: and that of the mountains of Lorraine, of Franche Compte, and the neighbouring countries, imitates very perfectly the manufacture of Gruyere. Auvergne cheese is as good as the best Dutch."

We have seen and tasted a French cheese which is made with fenugreek, and has exactly the smell of a pig-stye. We know not in what part of the kingdom it is manufactured. "Cheese," says Mr Marshall, "of the first quality, or which comes as near perfection as the nature of it admits, or as art can probably approach, is of a close even contexture; of a firm but unctuous consistency: of a mild flavour while young, acquiring by age an agreeable fragrance. Cheese of this description, like wine of a good vintage, improves by age in mellowness and flavour."

The principal defects of cheese are porousness, hollowness, dryness, partial rottenness, pungency, and rancidness. The two last of which seem, by the experiments of Mr Marshall, to arise from the formation or disengagement of an *essential oil*. Probably the austere flavour of Cheshire cheese depends upon the same cause.

Imperfect state of the art of cheese making.

Though cheese-making has been now practised for more than 4000 years, it is still only in its infancy, and little else than mere empiricism. Two reasons may be assigned for so extraordinary a fact. In the first place, the difficulty of the art itself, arising from the variety of circumstances on which the quality of cheese depends; and in the next place, the manipulations of the process having been hitherto entrusted almost solely to women. We are far from intending by this to throw an imputation on the sex. In the words of Mr Marshall, "they have by a natural cleverness done much;" but having failed, after a long, and, we should think, an ample space allotted them for trial, to bring the art to that perfection of which it is certainly susceptible, they should not reject such aids as are now offered them by others. We express ourselves in this manner, because we have reason to believe that the operations of the dairy-room are considered by some women as a sort of Berecynthian mysteries, on which the uninitiated eyes of the other sex are not permitted to look, and that it requires no little address, and some degree of interest, to be admitted to the knowlege of its rites.

Importance of management.

On the importance of proper management in the process of making cheese, as well as in the making of butter and every other object connected with the dairy, no writer expresses himself more strongly than the intelli-

Dairy.

gent and experienced Dr Anderson. He is disposed to ascribe to this, at least in a great degree, even the striking difference that exists betwixt Gloucestershire and Cheshire cheese; for the milk, he says, of which these two species are made, differs very little. It is generally supposed that richness, or the proportion of oily matter contained in cheese, is the cause of its agreeable flavour; but Dr Anderson cannot admit this to be the fact; for Parmesan and the small round Dutch cheeses are both deemed by most persons to be of the best flavour, and yet they are made of skimmed milk. Dr Anderson had, in his own house, a small round Dutch cheese made of skimmed milk, which, to the palates of most people who tasted it, appeared, he says, richer and more pleasing than very excellent North Wiltshire cheese. He had likewise seen cheeses made of the same kind of milk with the Suffolk cheeses, "which had nothing of that horny hardness and indigestible quality for which they are remarkable."

Medical qualities of cheese.

As the milk of such animals as live solely on vegetables is of an intermediate quality, betwixt animal and vegetable food, we may infer, that the cheese prepared from this milk will partake of the same nature; and it is understood to constitute the strongest and most nutritive part of the milk. But when separated from the other parts, it is probably less digestible.

Pure cheese, or that which is dry, and has been prepared from skimmed milk, is very indigestible; but that which has had left in it a portion of the oily or butyraceous parts, is understood to be less so, and more nutritious.

Cheese is frequently eaten after having been toasted, by which means it is deprived of a portion of the oily matters it contains, and the other parts are made to adhere more closely together. This food can be digested pretty well by stomachs that are good; but it is certainly improper for the weak, and such as are liable to dyspeptic affections. Probably, however, the small quantities of cheese that are usually eaten at the tables of the rich, have very little effect either one way or other.

Putrefaction.

Cheese is liable to putrefaction; and as this advances, becomes acrid and more stimulant, partly from the evolution of an empyreumatic oil and other substances, and partly from the numerous insects which are generated in it while in this state. It can now scarcely be eaten in such quantity as to be esteemed an aliment, and is only used as a kind of seasoning or relish. It is thought to excite the stomach to the digestion of other food. Ewe cheese digests more easily than that which has been made from cow's milk, but is less nutritious; and goat cheese is more easily digested than either, but is also less nourishing. Physicians advise cheese to be eaten only in small quantities, and quote the following Latin verse:

"*Caseus ille bonus quem dat avara manus.*"

"That cheese is best which is given with a sparing hand." Some of them condemn the use of it altogether, and refer us to the old maxim:

"*Caseus est nequam quia concoquit omnia se quam.*"

A maxim which shews that cheese has been long thought to be a stimulant, assisting in the digestion of other food, whilst it itself remained undigested: an idea, however, which is entirely without foundation. Dair || Dalecarlia.

DAIS, a genus of plants of the class Decandria, and order Monogynia. See BOTANY, p. 214.

DAL. See DALECARLIA.

DALBERGIA, a genus of plants of the class Diadelphia, and order Decandria. See BOTANY, p. 279.

DALEA, a genus of plants of the class Diadelphia, and order Decandria. See BOTANY, p. 279.

DALECARLIA, DALLAND, THALLAND, or DALARNE, is a province in the kingdom of Sweden, which is bounded on the east and north by Norway, Helsingeland, and Gestrickland; and on the south-west and south by Wermeland and Westmannland. It stretches from a little southward of the river Dal, which is somewhat beyond the 60th degree of north latitude, nearly to the 62d degree; and if we suppose it to reach to the Gulf of Bothnia, it extends over five degrees of longitude.

Dalecarlia, as its name imports, has a great variety of hill and dale; and besides several lakes of different sizes, it is watered by two large rivers, and a great number of small streams. The principal rivers are the Dal, the Ljusne, and the Clara. The Dal, which rises among the mountains on the frontiers of Norway, runs through the southern part of the province. It is a slow running river, and is too shallow for the purposes of navigation. From the great and sudden swells to which it is liable, it has been found impracticable to build over it a stone bridge; but as the road to Fahlun crosses it twice, this defect has been ingeniously supplied by a wooden bridge of a very singular construction. A large stage formed of huge square trees, floats so that the upper part is just on a level with the surface of the river, and they are so connected with the banks that they cannot be carried away by the stream. A close row of square trees, about 12 feet long and 9 inches thick, and lying in the direction of the river, is fixed on the middle of the stage, and forms a floating bridge, across which a man may walk without wetting his feet; when it is loaded with a carriage, it sinks a few inches. It is obvious that this bridge can be crossed with the same facility whether the water be high or low. It is particularly secure, and has a wooden parapet on both sides.

Rivers.

The river Ljusne, which waters the northern part of the province, is nearly as large as the Dal, and has its origin in the same mountainous tract. The Clara has its origin among the same mountains, and after running south through Wermeland, discharges itself into the Lake Wenner.

General aspect.

The general character of Dalecarlia is that of a mountainous country, excepting the southern part of the province, near the river Dal. The highest mountain is Fjall, in the parishes of Lima and Särna, near Norway, which rises nearly 3000 feet above the level of the sea. It is a part of the great chain called the Doffrine hills. The rest are much smaller, and are in general round-backed knolls, covered with forests of pine. Two subordinate ranges of hills stretch from the great chain already mentioned, at the place where Fjall stands, and cross Sweden in a south-easterly direction, gradually decreasing both in height and size. One of them passes across the north of Dalecarlia, which it separates from Herjeodal, Helsingland, and Gestrickland. The other, which is the most southern, after running between Wermeland and Dalecarlia, takes a southerly

Mountains.

Dalecarlia.

course, crossing Nerike and part of West Gothland, and ending at the northern part of the Lake Wetter. The principal lake in Dalecarlia is Siljar, Sillian, or Sion, which is seven Swedish miles long, and about a quarter of a mile broad. The river Dal runs through this lake.

Agriculture.

According to Mr Marshall, the country in the neighbourhood of Hedmora, a considerable commercial town, is almost completely barren. The peasants cultivate and inclose small fields round their cottages, merely for the subsistence of their families. The soil is not hard, and a single ox or cow is sufficient to draw the plough. A very small quantity of wheat is reared, the principal productions being oats, barley, and beans. Their cattle are small, but strong. In the neighbourhood of Grodoeu, they often sow and reap in seven weeks, and Mr Marshall informs us that he has seen fields as beautiful as those in England. The proprietors of the forests have established agents, who employ the peasants in cutting down the wood, for the purpose of making pitch, turpentine, and charcoal; and though they are good workmen, yet they earn only about nine sols Tournois, which, with the produce of their farms, is sufficient to support them. In the vicinity of Lynna, agriculture is in a more advanced state. There are some farms that consist of about 70 English acres, and even some that contain 300.

Mines.

Dalecarlia is celebrated for its rich mines. The famous copper mines of FAHLUN will be fully described under that article. About a quarter of a mile from the town of Sather, upon the lake of Linster, is the copper mine of Boisberg. In the same part of the country is the silver mine of Silfwerberg, which was formerly celebrated; but the pits, which are very large, are now filled with water. It was worked with great success in the reign of Queen Margaret, who granted it several privileges. The ore in the eastern part of the mine contains from 28 to 30 grains of gold for every pound of silver.

Eldfal, which is celebrated for its porphyry mines, is situated on the north of the Lake Siljar, and a little to the east of the river Dal. Huge blocks of porphyry are raised, and afterward hewn and polished on the spot, and many of the finest ornaments of Stockholm are formed of it. It is also manufactured into candlesticks, vases, paint-boxes, and other utensils, which are sold in the metropolis. This manufactory, which is under the care of Mr Hjelm, is the most complete in Sweden.

For a full account of the mineralogy of Dalecarlia, we are under particular obligation to Dr Thomson, who lately (1812) visited and examined that province. The following description of the province, which we have copied literally from Dr Thomson's *Travels*, as it is unsusceptible of abridgment, is principally taken from Hisinger's *Mineral Geography of Sweden*.

Mineralogy.

"In the south aud south-east part of the province, in the parishes of Rättoiks, Mora, Venjans, and Malungo, the rocks consist of the same species which are found in other parts of Sweden at a similar height; namely, red and grey granite, (gneiss) mica slate, primitive limestone, and sometimes, though rarely, primitive trap. In the north and north-west portions of the same parishes, we find these covered by beds of rocks, which belong chiefly to the transition class. These consist of gravel, conglomerate, hard flinty alpine sandstone, over which for a considerable extent lie hälleflinta* and jasper porphyry, transition greenstone, greenstone porphyry, porphyry breccia, and transition clay slate; all lying in beds, which approach more or less to the horizontal position. A conglomerate, consisting of sandstone breccia, and breccia saxosa, lies over this alpine chain of rocks in the Svackufjäll, Elgshoghan, Salfjäll, Mossevola, &c. which lie partly in Sweden and partly in Norway. Farther down, in the parish of Särn, is found alpine sandstone. Over this, in the parish of Elfvedal, within the division of eastern Dalelf, there is an extensive tract of transition porphyry, porphyry breccia, and transition greenstone, which continues over a part of the parishes of Mora and Orssa. Round western Dalelf, in the parish of Lima, are found alpine sandstone, clay slate, trap, and trap porphyry, all belonging to the transition rocks.

In the parishes of Rättvik, Ore, Orssa, Mora, and Sophia Magdalena, there occur beds of transition rocks, consisting of sandstone, limestone, clay slate, and marl slate, interspersed with petrifactions, and of posterior formation to the preceding rocks, which they in part cover. Respecting this tract, the following observations may be made.

1. The aspect of the surface is usually uneven, some few plains excepted, as for example, the sandy plain between Rättvik and Boda chapel; that between Dalby and Furndal, in the parish of Ore; the plain of Skatunge, and the north part of Solleröns. The beds of limestone at Vika and Vomhus, in the parish of Mora, are likewise disposed into plains. Finally the surface is broken into alternate heights and vallies, the beds of which either constitute oblong or level ridges, as those about Boda and Osmundsberg; or they fill up hollows and precipices consisting of older rocks, the flanks of which, to a greater or smaller extent, consist of these beds. This is the case at Digerberg, in Orssa by Skatunge chapel, and at a height between Vikarby and the church of Rättvik, &c.

The heights round the lakes of Siljar and Orssa are very low: at Vomhus, Vika, Omon, near Sollerön, and at the foot of Digerberg, they lie almost on a level with the surface of the water, and probably constitute the bottom of the lake Orssa. On the other hand, at Glekärna in Rättvik, they occur, according to Cronstedt, nearly 200 fathoms above the surface of the lake Siljar, and at Osmundsberg they are still higher.

The boundaries and circumferences of the different beds can hardly be ascertained with accuracy, on account of the forests and alluvial earth with which they are covered. That part of the lake Siljar which is called Rättvik is surrounded with beds of limestone, which lie over rocks of granite and mica slate, from Osbäck, five-eighths of a Swedish mile south from Rättvik church, to Ick-on in the same parish. From Rättvik these beds are continued in a north-easterly direction to Boda chapel, and they may be seen still farther north in the parish of Ore. They are found likewise in Rättvik near Beäckby, Alsorby, Kyrkan, Vikarby, Oiga, Ostbjörka, and the village of Gliskärna.

Beds of limestone are found likewise in the parish of Mora, by Vomelf and Vomhus chapel, and near the village of Vika and Selbäcks. The beds found at Vika are a continuation of those at Sollerön.

Sollerön parish and that of Sophia Magdalena consist for the most part of a flat round height of red granite

* This word, used by Cronstedt, is applied in Sweden to quartz, hornstone, and compact felspar. The porphyry alluded to is felspar and clay porphyry.

Dalecarlia. Mineralogy.

(gneiss), which towards the north and north-west sinks into a level plain. Over the lower side of this height passes transversely a bed of limestone, and a little to the north of it at Utanmyra sandstone occurs.

The curvilinear extent of this bed from Rättvik near Boda, Ore, Skaturgby, and Orssa, to Vattnas in Mora, amounts to about 46⅔ English miles. Its breadth may be estimated at about 6⅔ English miles; but this breadth varies considerably in different places.

2. Sandstone and limestone, which sometimes contains posterior beds of clay slate and marl slate, intermixed and composed of the substances that have been named in the preceding table of the transition rocks.

The sandstone in this tract, as is the case with the same rock in other parts of the kingdom, constitutes always the lowest bed. Beds of it with limestone are seen at Sollerön, near the grindstone quarry in Orssa, a quarter of a mile (1⅓ English mile) from Dalby in Ore, and in a variety of other places. These beds dip to the north-north-west and north, at an angle of between 30 and 40 degrees; while the limestone dips to the west at an angle of about 49 degrees. At Styggforss in Boda, the sandstone beds lie immediately over the primitive rocks, and are accompanied by marl slate and limestone. At Sollerön, and by Vikarby, limestone beds are found lying immediately over granite.

Limestone, with intermingled beds of clay slate and marl slate, constitute the uppermost bed. The clay slate and marl slate are found only in the upright beds, surrounded by the common limestone, to which the strata are parallel, though the beds are not particularly level. Examples of this may be seen on the north-west side of the cliff of Osmundsberg, at Styggforss, at Skatungbyn, in the enclosure near the river Ore, where layers of thin slaty clay slate, running east and west, and dipping at an angle of 23 degrees to the north, are surrounded with parallel beds of limestone. By Vikarby in Rättvik, the whole height upon which the village is situated, rising gradually from Siljar, consists of beds of limestone running in an east-north-east and west-south-west direction, and dipping at an angle of 25 degrees towards the north-north-west. Near a windmill in the same place occurs a bed of grey clay slate, 22 feet thick, running in the same direction, and dipping at a similar angle with the surrounding limestone.

The rocks that lie over these beds are dissimilar both in age and materials. North-east from Siljar, Orssa lake, and Ore river, the covering rocks consist of transition porphyry and trap. About the eighth part of a Swedish mile from the limestone beds, south from the village of Vongsgjärd, on the road to Mora, at the foot of the Digerberg, there is a red conglomerate of quartz and jasper, and beside it a rock composed of quartz and hälleflinta. Farther down about one-eighth of a Swedish mile nearer the north in Mora, there is a compound rock, consisting of blackish brown heavy greenstone and yellowish, reddish, and greenish quartz, with cornelian red lines and streaks; but, in consequence of a multitude of rents and cracks, so brittle that it falls to pieces upon the smallest blow.

3. The position of the beds is very various. One half of them retain their primitive position, and are either horizontal, or elevated a few degrees by the primitive rocks on which they lie. Others are raised almost to a perpendicular position. At Utanmyra near Sollerön lie sandstone beds nearly in a horizontal position. The same thing occurs at the whetstone quarries between Kalmora and Nederberga. Horizontal beds of limestone are found at Vombus, Vika, Sollerön, Farndal, and Dalby. At Grano they dip north-north-west and north, at an angle of about 10 degrees. On the contrary, there occurs a whole tract of limestone, the beds of which are either perpendicular, or incline at an angle at least greater than 40 degrees. This tract is situated between Boda chapel and the hill of Osmund.

The hill of Osmund, half a Swedish mile from Boda, constitutes the highest point of the whole tract. The summit of it is 40 fathoms above the surface of the nearest lake. This hill is composed of the following beds: immediately under the soil, loose brown clay slate (slate clay), 12 feet—coarse grey fuller's earth, 4 feet—dark grey fine clay slate (slate clay), 1 foot—brown limestone, 1½ foot—loose brown clay slate (slate clay), ½ foot—greyish brown limestone, 1½ foot—loose clay slate (slate clay), decrepitating in the fire—compact brown limestone, 1 foot—loose brown clay slate (slate clay), with balls of limestone from an inch to a foot in length, and containing a great deal of petroleum, 2 feet—bituminous limestone, ½ foot—brown clay slate (slate clay), ½ foot—blue clay, containing some silver, 1 inch—below all these comes the common primitive limestone of the country.

4. The sandstone is composed of fine siliceous matter mixed with oxide of iron and clay, and often contains some lime. The varieties of it are as follows:

Light grey fine grained sandstone, varying in colour from white to dark grey, and differing in hardness. Found at Kallmora, Styggforss, Sollerön.

Light grey sandstone, with streaks of red iron shot clay. Kallmora.

Pale red fine grained sandstone, lighter and darker coloured. Kallmora, Galleros.

Pale red fine grained sandstone, with round white spots. Styggforss, Karfsos.

The limestone exhibits the following varieties.

Compact limestone, sometimes grey, sometimes reddish brown, in distinct beds; the former with green spots, the latter with green and yellow veins.

Limestone, with a splintery fracture, translucent, reddish, yellow, and white, with cavities filled with calcareous spar, stalactites, and petroleum. At Dalby lime quarry.

Grey and reddish limestone, mixed with sand. The hill near Rättvik's church.

Red and white lumachella with small white anomiæ and entrochi, in reddish brown limestone. At Karfsos.

Calcareous spar. At Gliskärna, Forndal, &c.

Grey and red marl slate. At Styggforss."

Inhabitants.

The inhabitants of Dalecarlia differ very much from the rest of the Swedes, both in appearance and manners, and, like the Scotch Highlanders, whom they in many respects resemble, they have always been celebrated for their integrity and courage. The porters and labourers in Stockholm are from this province, and wherever they go, they retain the original dress of their country. The men wear long coarse coats of a whitish grey colour, with buttons of horn or leather. They use a leather girdle; and their hats are like those of the Quakers of this island. Their military character stands very high, and their bravery has frequently saved Sweden. The Dalecarlian regiment enjoys the same reputation in the Swedish army as the 42d does in ours.

Language.

The language of the Dalecarlians is supposed to resemble that which is spoken in the Lowlands of Scotland; and Dr Thomson mentions, that a Dalecarlian who landed at Aberdeen was understood by the people of that town. Professor Eubergius states, that the Dalecarlian tongue is so like the Icelandic, that when the latter is

Dalechampia || Dalkeith.

pronounced in the Dalecarlian accent, it is mistaken for the Dalecarlian.

Population.

According to Peuchet, the population of this province is about 120,000. The principal towns are Fahlun, Hedmora, and Satta; and the chief villages are Lecksand, Mora, Rattwik, and Funa. Each of these parishes is supposed to contain about 9000 inhabitants. See Thomson's *Travels in Sweden during the Autumn of* 1812, chap. vi.; Coxe's *Travels*, vol. v.; and *Promenade d'un François en Swede par de la Tocnage*, 1801. (*j*)

DALECHAMPIA, a genus of plants of the class Monœcia, and order Monadelphia.

DALEBORDIA, a genus of plants of the class Icosandria, and order Polygamia. See BOTANY, p. 233.

DALKEITH, from a Gaelic word which signifies a plain between two rivers, is a town of Scotland in the county of Mid-Lothian. It is beautifully situated on a pretty high ridge of ground between the two rivers called the North and South Esk, but nearest the North Esk, from which the ridge has a rapid ascent. The principal street, which is straight and broad, stretches from east to west. At its eastern extremity is the gate which conducts to Dalkeith House, the principal seat of the Duke of Buccleugh, and nearly at its other extremity a street branches off to the South Esk, and another to the North Esk, both of which rivers are crossed by good stone bridges. The church and the jail, which are not remarkable as public buildings, stand in the principal street. Several manufactures have been established in this town, which are carried on with great activity. The following are the principal. A hat manufactory, which gives employment to about 12 men and as many women. Mr Hislop, to whom it belongs, has likewise a manufactory near Manchester, for the purpose of making coarse hats, a branch of the trade which can only be carried on with advantage in that part of the country. At the iron foundery under Mr Mushet, all sorts of cast iron goods and smith work are manufactured. The pig iron is brought from Omoa, Calder, and Shotts iron works, at the rate of twenty-one shillings per ton of land carriage. There is also at Dalkeith a tannery, a soap-work, and candle manufactories. Dalkeith is principally celebrated for its corn market, which is held every Thursday, and which is one of the largest in Scotland. A charity school on Dr Bell's plan was established in 1813, by the Duke of Buccleugh, who is at the sole expence of paying the teacher. It already contains 70 boys.

Dalkeith House, which is situated a little to the east of the town, is a large building, with wings projecting in front, and is erected on the site of the old castle of Dalkeith. The grounds, which are exceedingly beautiful by nature, and laid out with great taste and judgment, occupy the tongue of land formed by the North and South Esk, which unite about half a mile below the house. A great number of fine oaks, and trees of all kinds, adorn the park. The North Esk is crossed by a handsome stone bridge of one arch, seventy feet wide and forty-five high; and the banks of both the rivers are cut into extensive walks. The noble possessors of this princely estate have been long distinguished for all the virtues which give to rank and fortune their truest splendour. The discrimination with which their benevolence is directed, and the delicacy with which it is proferred, could not easily be concealed; but the extent of their charities will probably never be known, but to the numerous individuals of almost all ranks in society whom they have relieved and rendered happy. It is not the province of a work like this to record acts of private beneficence, however noble and affecting; but virtue sometimes appears in such a form as to command our admiration; and while our pages are constantly filled with the praise of talents and genius, we could not refuse a tribute of admiration to a system of benevolence, unexampled and almost unlimited.

Dalmatia.

About a quarter of a mile from Dalkeith, on the South bank of the South Esk, stands Newbottle House, the seat of the Earl of Ancrum.

Population of the parish of Dalkeith in 1811, 4709; number of houses 534, number of families 1131. (*w*)

Boundaries.

DALMATIA, a country in Europe, bounded by Servia on the east, Croatia on the west, Bosnia on the north, and the Gulf of Venice, or Adriatic Sea, on the south. Including the isles which lie along its coasts, it extends from 12° 10′ to 16° 40′ of longitude, and from 42° 25′ to 45° 35′ of latitude. Subject, however, to many irregularities in its outline, it does not contain such an extent of surface as this measurement appears to give. It derives its name from its ancient capital Delminium, and formed a part of ancient Illyricum, or Illyris. The other part was Liburnia; but both are now included under the common name of Dalmatia, though the Austrian government has, in modern times, thought proper to revive and employ the ancient name Illyria. This country has undergone a great variety of revolutions, of which, however, the limits of this article do not admit of any detailed account. Under all the changes of dominion to which it has been successively subjected, it does not seem to have received any improvement; for, though possessed of many advantages, it is still very far behind in every thing almost by which a country rises to eminence and respectability. Its last masters were the French, who have now (1814) retired from its territory, and abandoned it to the Austrians, Russians, or Turks, as they may happen to think their rights or their interests involved.

Dalmatia has a great deal of elevated, rugged, and barren ground, and abounds in scenery, which, for magnificence and sublimity, can scarcely be surpassed. There are also many parts of it vallies equally beautiful and fertile, tolerably well cultivated, and covered with flocks of sheep and cattle. Some of its rivers are navigable for a considerable way. The whole coast is deeply indented with creeks and bays, and bordered with a great number of islands.

Agriculture, &c.

The cultivation, upon the whole, is extremely bad, both on the continent and on the islands. The people are destitute of skill, enterprise, and stimulus. Indeed they are mostly in a barbarous or piratical state; and though they were capable of improving the country, and raising from it all that it could produce, still the insecurity which hangs over the fruits of their exertions, would prevent them from making any steady and persevering efforts. The proprietor is the slave of his tenants: what they pay in rent, is rather given to him as an alms, than demanded by him as a right; when he complains, they threaten him with their vengeance, and sometimes oblige him to supplicate them to spare his life. They are so rude, and have so many ways of escaping, that he has no hold of them, and is entirely at their mercy. Agriculture of course is much neglected, even where it might be carried on in the easiest way, and with the greatest success; and, instead of having abundance of wholesome food, the people are sometimes under the necessity of subsisting for several months of the year on wild roots. The cattle are numerous enough, but extremely small; so that, as they are employed in labouring the fields, and as the plough

Dalmatia.

must be accommodated to their strength, the ground is very superficially wrought. There are sheep to furnish the inhabitants with wool; but its quality is not good. The best is found at Bossiglina, in the district of Trau. Dalmatia produces maize, wheat, pulse, grapes, olives, figs, almonds, and various other kinds of fruit. There are no potatoes. Two sorts of manna also might be procured, one from the ash tree by incision, and the other from a species of grass; but the inhabitants know not how to appreciate such sources of subsistence and wealth. The shell fish found here are remarkable neither for variety nor beauty. Most of the mills in Dalmatia have their wheels placed horizontally, and their spokes terminating in a kind of spoon. At Zara, they manufacture the liquor called marasquin, so much celebrated in most of the cities of Europe. It is made of marasques, a species of cherry. The stone of the fruit gives the liquor its peculiar flavour. In the county of Trau, the vine and olive tree are cultivated to a great extent, and in great perfection; so that from that small district alone, there are produced annually 13,000 barrels of excellent oil, and 50,000 hogsheads of remarkably good wine. It furnishes also 300,000 lb. of dried figs, a great quantity of almonds, 400,000 lb. of cheese, and wool in proportion. The inhabitants of Morter make a kind of coarse cloth from the threads of the broom, which they are very industrious in gathering. This cloth, however, is too coarse for apparel, and is only employed for making sacks, and packing up merchandise. In all the islands, fishing is a general avocation. The fish is salted and sold, which brings to those who are engaged in the employment a very considerable revenue. The fishing, however, is neither applied to with that eagerness, nor carried on with that judgment, which are necessary to success. It was once in a flourishing state, but has latterly declined very much. In the lakes and rivers there is abundance of salmon, trout, eels, &c. The sea fish are mackarel, pilchards, mullets, congers, gold-fish, tunnies, &c. There are also dolphins and porpoises.

Rivers.

Cettina.

The principal rivers of Dalmatia, are the Cettina, the Kerka, and the Narenta. The *Cettina*, which is the Titurus of the ancients, takes its rise at the village of Zarebiza. In the opinion of M. Busching, the Abbe Fortis, and others, the four springs which constitute its sources, are ramifications of a subterraneous river. Of this, there are several presumptive proofs; the most important of which is, that in one of the springs, which is remarkably deep, excellent trout of a considerable size are caught. These, it is alleged, could only get there on the supposition that is alluded to. It is a curious fact, that, according to the observation of the country people, the sources of the Cettina rise and fall in regular proportion to the rise and fall of the Lake Buscoblato, which is situated at a distance of twenty miles, and separated by very high mountains. This circumstance has led them to conclude, that there is a direct communication between the two. The course of the Cettina is wild and romantic. It seldom runs through a plain of any length, but for leagues together dashes from rock to rock between perpendicular mountains, where it seems to have cut a passage for itself from the very surface to the very bowels of the earth. Near the fort of Duaro, it forms a very grand cascade. Its breadth is about seventy feet, and it falls vertically from an elevation of a hundred and fifty, amidst vast rocks irregularly piled upon one another, unrelieved by one vestige of vegetation, and inhabited only by screaming vultures of an enormous size. Having escaped from this horrid cataract, it pursues its way for about a quarter of a league, when it arrives at a precipice twenty feet in height, and forms another cascade. Here, however, the scene changes,—verdure and trees and flowers appear in all their beauty, the mountains decline into wooded hills, and these again into plains and meadows, through which the Cettina flows slowly and majestically, till it falls into the sea not far from the dismantled fortress of Vissach.

Kerka.

The *Kerka* was called Tatius by the ancients, and formerly separated Liburnia from Dalmatia. It originates in a grotto at the foot of the mountain Topoli—runs in a south-west direction—traverses the lake of Scardona, which is distant from its source about thirty miles—and, issuing from thence, proceeds a few miles farther on, to form a lake about two leagues in length, and empties itself into the sea through the narrow strait of St Antonio. On this river there are several very fine cascades. The most celebrated are those at Rochislap and Scardona. At Rochislap the river is of considerable width. A bridge, after the Turkish fashion, has been thrown over it, consisting of no fewer than sixty arches. And this, together with some mills, several cottages, and islands covered with trees, render the scene beautiful, independently of the fall of water, which itself is not very great, being only five-and-twenty or thirty feet, but is rendered beautiful by its being divided into twenty separate rivulets, some of which tumble rudely over the rocky precipices, while others pour gently through chasms, which have been gradually formed and polished by the friction of the currents. The cataract at Scardona is far more magnificent. It is not quite so large, but fully as grand and striking, as the falls of Niagara. M. Cassas gives a fine description of it: "At the foot," says he, "of the first three shelves, or steps, where the river divides, the united summits of a few trees, whose trunks are concealed by a variety of objects in the fore ground, intersect with a verdant line the whole width of the cascade; but as the water approaches it becomes still wider. A semicircular terrace, prolonging its colossal propulsion over the abyss which receives it, thus curbs its velocity. The immense body of water fills the noble contour of this long and heavy terrace. The land seems to tremble from a distance by the weight of its fall; the air, on being displaced by the water, seems at first to hiss or sigh; which sound at length increases, till the noise is so terrific that the ear is not able to sustain it; nor can the eye at last comprise the extent of the view, or the mind sufficiently admire the awful appearance of the whole." On approaching nearer, "all is changed, and nothing prevails but confusion, chaos, or the most horrid distraction. There are then no longer to be seen that uniformity of masses, that beauty in the groupes, that majesty in the combination; but we behold innumerable rocks, broken, steep, and dispersed, presenting frightful points, which appear to be rising from behind the water and the trees. It is no longer a river, but an ocean, roaring and rushing with fury against the shapeless masses which obstruct its course."

Narenta.

The *Narenta* is in the eastern district of Dalmatia; it rises from the swampy lake of Mostar, and after running a pretty long course, and receiving several tributary streams, empties itself by three mouths into a gulf of the same name. This river is large, but does not admit of navigation far up by any boats, but those of a small size. Its waters are brackish above twelve miles from the sea. The tide flows considerably farther. It abounds in a variety of excellent fish. The plain through which the lower part of it flows is of a rich and pro-

Dalmatia. ductive soil, but by no means in a proper state of culture. Besides the large rivers now described, there are many more of considerable size, on whose banks there is a great deal of beautiful and romantic scenery. There are also several lakes of large extent, and well stored with fish. The principal of these are Vrana, Scardona, Sebenico, Rastoc, Saschero, Desna, Sablachia, and Morino.

Towns. The principal towns of Dalmatia are Zara, Spalatro, Sebenico, and Salona. Of these places, which are on several accounts worthy of notice, some description will be given afterwards. It is remarkable, that so few of the multitude of towns which formerly existed in this country are now to be seen. Not only are their walls and monuments destroyed, but they are absolutely depopulated. This unusual fact is probably to be traced to the contests carried on by the Venetians and Turks; the former of whom were too feeble to protect their conquests, and the latter at too great a distance to retain them. In consequence of this, nothing but plunder, devastation, and carnage, followed in the train of those wars in which these two powers so long contended for the dominion of Dalmatia.

Minerals. Dalmatia abounds in marble. It is to be found both white and variegated. Generally it contains the remains of vegetable and marine productions; and sometimes it is pervaded by matter of volcanic origin. Its quality is various; some of it beautiful and excellent, but a great proportion of it false or dull in the colours, full of gravelly particles, harsh therefore under the chissel, and not susceptible of a fine polish. There are masses of gypsum near Scign, and in other places. That which is found near Scign is of a finer quality than that taken from Ancona, which is used at Venice. Many parts of the country indicate the existence of volcanoes at a remote period. This is the case particularly at Krin, which is situated in the course of the Cettina, and at Knin, which lies near the source of the Kerka. Marle of the most perfect whiteness is met with in the district of Zara. In the grottos from which the Cettina takes its rise, there is a great quantity of stalactites; and petrifactions of various kinds abound throughout the whole country. There is a mine of ironstone not far from Scign; and mines of the same substance are also found in the territory of Knin. In ancient times this country produced a vast quantity of gold. Pliny relates that in the time of Nero it furnished fifty pounds of gold per day; and Martial gives it the appellation of *terra aurifera*. Now, however, this metal is never met with; neither is there any proof of mines of silver and mercury, though that is the common opinion and report among the inhabitants. In the island of Bua there is an extensive mine of asphaltes.

Antiquities. Dalmatia is a rich, entertaining, and instructive field for the antiquarian. Of the many objects which deserve his attention, are the triumphal arch at Pola, called Porta Aurea; the amphitheatre and temple at the same place; the palace of Dioclesian, &c. at Spalatro; the walls of Asseria or Podgrage; and the ruins of Salona.

Islands. The islands on the coast of Dalmatia are extremely numerous: *Lissa*, which is about thirty miles in circumference, and has a temperate climate, some fertile vallies, and a good fishing coast; *Pelagosa*, which is composed of lava, is subject to frequent earthquakes, and has all the appearance of being recently produced by a volcano; *Lesina*, which is 44 miles long, and 8 at its greatest breadth, rocky and sterile in the heights, but covered with corn and fruit trees on its coasts, and better peopled than any other of the Dalmatian isles; *Brazza*, which is 32 miles in length, and not more than 9 in breadth, is rough and mountainous, produces wine, however, and cattle, but is liable to be parched; *Ulbo* and *Selva*, which are well inhabited, have plenty of cattle, but want good water, and produce little corn; *Uglian*, which would be productive if the inhabitants had sufficient skill, and if, like almost all the other islands in that quarter, it were not deficient in water; *Arba*, which is 30 miles in circumference, contains about 3000 inhabitants, and produces sheep, grapes, olives, and some corn; *Zuri*, &c. &c.

Inhabitants. The people of Dalmatia may be divided into three classes: those who reside in the towns on the coast; those who live wild on the mountains; and those who inhabit partly the mountains and partly the vallies. The first class are properly *Italians*. They have all the characteristics of that people. They speak the same language. Their religion, manners, and customs, are the same. They are distinguished by the same habitual politeness, the same innate servility, the same irresoluteness and timidity, the same want of every thing great and patriotic, the same love of intrigue, duplicity, cabal, and superstition. In short, they exhibit all those features of littleness and degradation, which usually mark a people, who, though originally virtuous and mighty, have first become enervated by corruption, and then being subdued by foreign powers, have added all the evils of national slavery to those of luxury and licentiousness. They are just what we have been taught to consider the Romans in the last period of their degeneracy.

Italians.

Haiducks. The second class consists of a small but growing number of miserable beings denominated *Haiducks*. These are not to be regarded as a distinct nation, according to the opinion of some writers. The word *haiduck* signifies originally the chief of a party or a family. In Dalmatia, it is employed to designate a criminal, fugitive, assassin, or highway robber; and, in fact, the Haiducks are of this very description. They live like wild beasts in the caves and forests of the mountains, exposed to all the rigours of the seasons; wandering amidst precipices that are almost inaccessible; clambering from rock to rock, that they may discover their prey at a distance; carrying off oxen and sheep, to feast upon their flesh, and make shoes of their skins; breaking into shepherd's huts, and taking by force whatever they need; and sometimes so urged by hunger and necessity, that a party of four will not only attack, but overcome and pillage a caravan of fifteen or twenty Turks. Against the Turks they have a native inveterate hostility, which they take every opportunity of gratifying. Religious zeal, inflamed by the language of their ecclesiastics, increases the hatred which, from various other causes, they bear against that people. A Haiduck thinks himself a man of great consequence, when he has succeeded in shedding the blood of an Infidel. The Haiducks, savage as they are, have some of those traits of generosity which are generally found among tribes in the same stage of society. Travellers are liable to be attacked and plundered by them; but they are faithful to every traveller who has the prudence and the courage to put himself under their protection, and trust to their fidelity. In this case they are never known to deceive. It is surprising, that the Haiducks are so forbearing to the people in the maritime parts of the country, whom they look on as the author of all their calamities and misfortunes. Another shade of ferocity added to their character, an augmentation of their numbers, which is likely enough to take place, and the appearance of some able and enterprising chief among them, might render them extremely formidable to the more inhabited and civilised parts of Dalmatia.

Morlachians. The third class of inhabitants are the *Morlachians*. According to Abbe Fortis, the name is derived from two words, *more*, sea, and *ulah*, black, and indicates, that they originally came from the Black Sea. One thing is evident, that their language, dress, customs, and character, demonstrate them to have had a different origin from the inhabitants of the maritime districts of the country. Among themselves, the Morlachians have several diversities, which seem to prove either that they were not of the same race from the beginning, or that some extraordinary revolutions have happened among them since they settled in Dalmatia. The Morlachians of the vallies of Kotar, and of the plains of Scign and Knin, are generally of a fair complexion, with blue eyes, broad face, and flat noses, and in character they are mild, honest, and docile. But the Morlachians of Douaré and of Vergoraz, a mountainous and sterile district, have an olive complexion, long countenance, and slender form; and are fierce, proud, bold, and enterprising. The Morlachians, who live at a distance from the sea and the garrison towns, are distinguished by probity and sincerity. These qualities lead them to put a degree of confidence in the goodness of others, which degenerates sometimes into good nature and simplicity. The Italians, by their tricks and impositions, have done a great deal to make them shy and suspicious, though they still show generosity and hospitality to strangers,—virtues which are practised alike by the poor and the rich. They are very punctual in fulfilling their engagements, and paying their debts. Ignorant of domestic economy, they resemble the Hottentots in some respects, and will often devour in a week as much provision as would serve them for many months. Their friendships are very durable. Indeed these are formed by religious ceremonies. In the Slavonian ritual, there is a formula for giving a public and solemn benediction to the union of two friends. This practice is not so prevalent as it was formerly. Equally strong and lasting are their resentments. A Morlachian will requite a favour, but he knows nothing about forgiving an injury. The Morlachians are naturally lively and ingenious; but the disadvantages of their situation have prevented them from making any considerable progress even in the most useful and necessary arts. With respect to religion, they are extremely superstitious, and believe firmly in ghosts, witchcraft, and enchantments. They belong partly to the Greek and partly to the Romish church. The two communions have an inveterate hatred at each other; and with regard to all ecclesiastical matters, are equally in a most wretched state. The manners of the Morlachians are simple. The female sex is treated with much contempt, and often with cruelty, especially after marriage. Their ordinary food is milk, prepared in every different way; and sometimes the flour of barley, wheat, &c. made into a sort of thin cakes. The cottages which they live in are mean, smoky, and ill furnished; and very rarely is a tolerably good house to be seen even in possession of the wealthy. They sleep on the ground wrapt in a large thick cloak. Their dress is simple and economical. When they go from home, they always carry a fusee over their shoulder. And when completely armed, they also take one or two pistols, and an enormous knife. They are much given to dancing, poetry, and music. The Abbe Fortis has given a specimen of their poetry in a funeral song, which has a great deal of simplicity and tenderness. See the *Travels of L. F. Cassas in Istria and Dalmatia*, by Jos. Lavallée; and *Voyage en Dalmatie*, par M. L'Abbé Fortis, trad. de l'Italien. (τ)

DAMASCUS, a celebrated city of Asia, and anciently the capital of Syria, may be accounted one of the most venerable places in the world for its antiquity. Origin. It is supposed to have been founded by Uz, the son of Aram; and is, at least, known to have subsisted in the time of Abraham. (Gen. xv. 2.) It was the residence of the Syrian kings, during the space of three centuries; and experienced a number of vicissitudes in every period of its history. History. Its sovereign, Hadad, whom Josephus calls the first of its kings, was conquered by David king of Israel. In the reign of Ahaz, it was taken by Tiglathpileser, who slew its last king Rezin, and added its provinces to the Assyrian empire. It was taken and plundered also by Sennacherib, Nebuchadnezzar, the generals of Alexander the Great, Judas Maccabeus, and at length by the Romans in the war conducted by Pompey against Tigranes, in the year before Christ 65. During the time of the Emperors it was one of their principal arsenals in Asia, and is celebrated by the Emperor Julian as, even in his day, "the eye of the whole East." About the year 634, it was taken by the Saracen princes, who made it the place of their residence, till Bagdad was prepared for their reception; and, after suffering a variety of revolutions, it was taken and destroyed by Tamerlane, A. D. 1400. It was repaired by the Mamelukes, when they gained possession of Syria; but was wrested from them by the Turks in 1506; and since that period, has formed the capital of one of their pashalics. Situation. The modern city, called Damas, Domeschk, Scham Sherif, is delightfully situated, about 50 miles from the sea, in a fertile and extensive plain, watered by a river which the Greeks called Chrysorrhoas, or golden river, but which is now known by the name of Barrady, and of which the ancient Abana and Pharphar are supposed to have been branches. Description. The city is nearly two miles in length from its north-east to its north-west extremity, but of very inconsiderable breadth, especially near the middle of its extent, where its width is much contracted. It is surrounded by a circular wall, which is strong though not lofty; but its suburbs are extensive and irregular. Its streets are narrow, and one of them called Straight, mentioned in Acts, ix. 11. still runs through the city about half a mile in length. The houses, especially those which front the streets, are very indifferently built, chiefly of mud formed into the shape of bricks and dried in the sun; but those towards the gardens, and in the squares, present a more handsome appearance. In these mud walls, however, the gates and doors are often adorned with marble portals, carved and inlaid with great beauty and variety; and the inside of the habitation, which is generally a large square court, is ornamented with fragrant trees and marble fountains, and surrounded with splendid apartments, furnished and painted in the highest style of luxury. The market places are well constructed, and adorned with a rich colonnade of variegated marble. Public buildings. The principal public buildings are: the castle, which is about 340 paces in length; the hospital, a charitable establishment for the reception of strangers, composing a large quadrangle, lined with a colonnade, and roofed in small domes covered with lead; and the mosque, the entrance of which is supported by four large columns of red granite, the apartments are numerous and magnificent, and the top is covered with a cupola ornamented with two minarets. There is shewn

Damascus. also the church of John the Baptist, now converted into a mosque; the house of Ananias, which is a small cellar or grotto; the house of Judas, with whom Paul lodged; the gate, where the apostle was let down in a basket; and, about half a mile beyond the east gate, the scene of his vision, which is marked only by a heap of gravel.

Population. The city is divided into 23 districts, each under a separate magistrate. The number of inhabitants is estimated by Volney at 80,000, by Browne at 200,000, and by others at 180,000. Of these, about 15,000 are Christians, and the greater part of the remainder Arabs and Turks. The people are generally described by the inhabitants of the surrounding countries as peculiarly mischievous and wicked. They are particularly intolerant towards Christians; and it is scarcely possible to appear in the streets in an European dress. But Dr Browne observes, that their pride in this respect is considerably abated, and that he found little difference between them and other Oriental citizens.

Trade. Damascus is the centre of the commerce of Syria; and its trade is rendered still more considerable, by its forming the rendezvous to all the pilgrims from the north of Asia to Mecca. Their number amounts every year to thirty or forty thousand; and many of them arrive in Damascus several months before the departure of the caravan. The city then presents the appearance of an immense fair, and every place is full of camels, horses, mules, and merchandize. Even in the year 1432, Brocquiere describes this assemblage of traders and devotees as remarkably numerous. "On the morrow of my arrival, I saw the caravan return from Mecca. It was said to be composed of three thousand camels; and in fact it was two days and as many nights before they had all entered the town." Caravans proceed from Damascus also to Bagdad and Grand Cairo; and the principal imports by these various channels are broad cloths and the different metals, which come from the coasts of the Mediterranean, and shawls, muslins, and other Indian stuffs, which are brought by the way of Bagdad.

Manufactures. Its own manufactures consist chiefly of silk and cotton fabrics; and of an excellent soap made of olive oil, kale, and chalk. Great quantities also of dried fruits and sweet meats, of their own produce, are exported to Constantinople, to the annual value of £40,000. Damascus was formerly celebrated for the manufacture of sabres, of such superior excellence, that they would bend to the hilt without breaking, while the edge was so keen as to divide the firmest coat of mail, and which are supposed to have been constructed, by a process now lost, of alternate layers of iron and steel. Tamerlane, when he took the city in 1400, is said to have carried into Persia their best artists in steel; but Brocquiere speaks of the inhabitants of Damascus in 1432 as still excelling in these manufactures. "The Damascus blades are the handsomest and best of all Syria; and it is curious to observe their manner of burnishing them. They have for this purpose a small piece of wood, in which is fixed an iron, which they rub up and down the blade, and thus clean off all inequalities, as a plane does to wood; they then temper and polish it. This polish is so highly finished, that, when any one wants to arrange his turban, he uses his sword for a looking-glass." "There are made at Damascus," he adds, "and in the adjoining country, mirrors of steel that magnify objects like burning glasses. I have seen some, that, when exposed to the sun, have reflected the heat so strongly, as to set fire to a plank fifteen or sixteen feet distant."

Gardens. Damascus is surrounded by a fruitful and delightful country, forming a plain nearly 80 miles in circumference; and the lands, most adjacent to the city, are formed into gardens of great extent, which are stored with fruit trees of every description. Besides the mosques and minarets, which are the usual ornaments of Turkish cities, the gardens are filled with pleasure-houses, turrets, and similar structures; a circumstance which altogether gives to the place the appearance of a noble city in the midst of an extensive forest, and fully justifies the appellation commonly given to it by Orientals, of goutah Demesk, orchard of Damascus. The pleasantness and fertility of these grounds are chiefly to be ascribed to the waters of the Barrady, which are distributed by numberless streams and rivulets in such a manner, that every garden has a fine run of water passing through it, at once fertilizing the soil, and supplying a variety of artificial fountains and ornamental water-works. So numerous are the fruit trees in the vicinity of the city, that those which are decayed supply the inhabitants with fire-wood; and, together with the walnut and Lombardy poplar, furnish also the principal materials for building. In these orchards the air is most salubrious, the soil remarkably productive, and the fruits, especially the apricots and grapes, as much distinguished by their superior flavour as by their extraordinary abundance. "No place in the world," says Mr Maundrel, "can promise to the beholder at a distance a greater voluptuousness;" and he mentions a tradition of the Turks, that their prophet, when approaching Damascus, took his station upon a certain precipice, in order to view the city; and, after considering its ravishing beauty and delightful aspect, was unwilling to tempt his frailty by going farther, but instantly took his departure with this remark, that there was but one paradise designed for man, and that for his part, he was resolved not to take his in this world.

Climate. The air or water of Damascus, or both, are supposed to have a powerful effect in curing the leprosy, or at least in arresting its progress, while the patient remains in the place. But, with all those advantages, the climate is represented by Volney as deficient in point of salubrity. The white waters of the Barrady are found to be cold and hard; the natives are subject to frequent obstructions; their fair complexions are considered as rather a sickly paleness, than the natural colour of health; and the excessive use of fruit, is productive, during the summer and autumn seasons, of intermittent fevers and dysenteries. Damascus is 23 leagues east of Sidon, 45 north of Jerusalem, and 65 south of Antioch. See Volney's *Travels in Syria and Egypt*, vol. ii.; Brown's *Travels in Africa;* Niebuhr's *Travels in Arabia;* La Brocquiere's *Travels in Palestine;* and Maundrel's *Journey from Aleppo to Jerusalem.* (q)

DAMASCUS, Pashalic of, is the first in Asia, and is one of the five into which Syria is divided. It comprehends the whole eastern part of that country, being bounded on the north and west by Tarabolos, on the south-west by Palestine, and on the east by the desert of Arabia. It extends from Marra on the road to Aleppo, as far as Hebron, in the south-east corner of Palestine; is bounded on the west by the mountains of the Ansares, Libanus, and the upper part of Judea; crosses the Jordan, including Jerusalem, Nablous, and Hebron; enters the Arabian desert towards the East, as far as the country is capable of cultivation; and, in the district of Tadmor or Palmyra, stretches fully five days journey in that direction. In this vast extent of country, the soil and its productions are extremely various. The plains of the Hauzan and the banks of the Orontes are the most fertile; and produce wheat, barley, dowra, sesamum, and cotton. The countries around Damascus and the Upper Bekaa, are of a reddish gravelly soil, better adapted for fruits and tobacco, than for the production of grain. The mountainous districts are appropriated to olives, mulberry, and fruit-trees, and in some places to vines, from which the Greeks make wine, and the Mahometans dried raisins. The office of the pasha of Damascus since the decline of the Turkish empire, is in a great measure hereditary; and the person, who holds that office, is invested with absolute power, from which there is no appeal. His public revenue is calculated by Mr Browne to amount to ten thousand purses, or half a million sterling; and arises chiefly from a duty upon lands, and the capitation tax paid by Christians. He possesses, indeed, other sources of emolument, particularly fines and arbitrary exactions; profits upon money lent to merchants and farmers, frequently at fifteen or twenty per cent.; and his privilege of heir to all the pilgrims who die on their journey to Mecca. His military establishment consists of six or seven hundred Janissaries, the same number of Barbary Arabs, who are little better than naked banditti, and eight or nine hundred Dellibashas or horsemen. These troops are employed, in the first instance, in collecting the *miri*, or land-tax; and every year, three months before the departure of the caravan to Mecca, he makes what is called his circuit, travelling through his territories, raising contributions from the towns and villages. These exactions, which are not always confined to the legal assessment, are seldom made without resistance on the part of the subjects; and particularly in the district of Nablous or La Maria, where the inhabitants are wealthy and powerful, the oppressions of the government are frequently withstood. But the most honourable office of the pasha of Damascus, and the regular occupation of his soldiery, is to protect the sacred caravan of Mecca from the plundering Arabs of the desert. He enjoys the distinguished title of Emir-el-Hadjé, or chief of the caravan, by office; and so important is this charge reckoned by every Mahometan, that when a pasha has acquitted himself well as conductor of the pilgrims, his person becomes inviolable even by the Sultan, and it is not permitted, on any account, to shed his blood. It is said, however, that, without departing from the letter of the law, the Divan sometimes extends its vengeance to those who are protected by this privilege, by ordering them to be smothered in a sack, or pounded in a mortar. The pasha of Damascus is not only charged with the duty of conducting the caravan, but also with the burden of its expences, which are calculated at five or six thousand purses, besides one thousand required for its own use on the journey. The advances for the caravan consist in the hire of camels for the pilgrims, the purchase of provisions in barley, corn, rice, &c. and the payment of certain sums to the Arab tribes, who dwell near the route, in order to secure a safe passage; though some of the more enterprising pashas have been known to conduct the caravan, sabre in hand, without paying a piastre to these plunderers. When the caravan sets out, the pasha receives from the governor of the castle the Sonjiak Sherifi, or ensign of the prophet, for which he gives a receipt in writing before witnesses, and which he solemnly pledges himself to bring back in safety. As soon as he arrives near the city, on his return, a messenger is dispatched to Constantinople, who is obliged to perform the journey in twenty-five days, and who carries with him water from the well Zem-zem near Mecca, and some dates from Medina to be presented to the Emperor on his visit to the Mosque. The following account from Mr Browne, of the pasha's entrance into Damascus, after the return of the caravan, will furnish the best idea of the power and attendance of this provincial despot. "First appeared three hundred dellis or cavalry, mounted on Arabian horses, variously armed and clothed, but on the whole, forming no mean display. These were succeeded by fifteen men on dromedaries, with musquetoons or large carbines, placed before them, and turning on a swivel in every direction. Some of the great officers of the city followed, well mounted and decently attired. Then came part of the pasha of Tripolis' Janissaries, well clothed and armed; that pasha himself with his officers and the remainder of his guard. Next was the tattarawan belonging to the pasha of Damascus, another body of four hundred dellis, a company of thirty musquetooners, a hundred and fifty Albanians in uniform, and marching two and two, like our troops. Before the latter was borne the standard of the prophet Sonjiak Sherifi, of green silk, with sentences of the Koran embroidered in gold, and the magnificent canopy brought from Mecca, guarded by a strong body of Muggrebins, or western Arabs, on foot. Then passed the pasha's three tails (generally of white horses) borne by three men on horseback; twelve horses richly caparisoned, and each bearing a silver target and a sabre; six led dromedaries, in beautiful housings; numbers of the chief persons of the city followed, among whom was the aga of the Janissaries, the governor of the castle, and the mohassel. Last came the pasha himself in a habit of green cloth, adorned with fur of the black fox, preceded by his two sons, all mounted on the most spirited steeds of Arabia, and followed by his household troops to the number of four hundred well armed and mounted. More than a hundred camels had preceded the rest, bearing the tents and baggage of the pasha." See Volney's *Travels in Syria and Egypt*; Browne's *Travels in Africa, Egypt, and Syria*; and La Brocquiere's *Travels in Palestine*. (*q*)

DAMASK, in the manufacture of cloth, is a variegated texture, richly ornamented with figures of flowers, fruits, landscapes, animals, &c. woven in the loom, and is by far the most rich, elegant, and expensive, species of ornamental weaving, tapestry alone excepted. The name is said to be derived from Damascus, which is thence inferred to be the original seat of this manufacture; but it is highly probable that this etymology rests more upon conjecture derived from affinity of sound, than upon any precise or respectable authority.

Damask belongs to that species of texture which is distinguished by practical men by the name of tweeling, or tweeled cloth, (French *touaille*,) of which it is the richest species. The tweel of damask is usually half that of full *sattin*, and consequently consists of eight leaves moved either in regular succession or by regular intervals, eight leaves being the smallest number which will admit of alternate tweeling at equal intervals.

In the article Cloth Manufacture, a representation has been given of the damask draw-loom, and some explanation of its principle and mode of operation. To these shall be added, in the present article, such further remarks on this curious manufacture as seem most important; and a few practical observations on the nature, operation, and use of the draw loom, the most extensive, complicated, and ingenious apparatus used in the fabrication of cloth.

The principle upon which the fabrication of ornamen[ts]

Damask.

tal figures, interwoven with tweeled cloth, is the combination of two lines at right angles to each other. That portion of yarn which is stretched in the loom, and which weavers distinguish by the name of *warp*, forms a superficies consisting of a very great number of parallel straight lines, contiguous to, or in contact with, each other, but until bound together by the intersection of the *weft* or *woof*, without any cohesion either chemical or mechanical. The intersection of the woof at right angles with the warp, forms the bond of cohesion, and gives the tenacity required tô form the flat substance called cloth. In the common texture the intersection is uniformly betwixt every individual thread, and the superficies of the cloth, when woven, presents a complete uniformity of appearance, all the intersections being uniform and equidistant betwixt every alternate thread.

The generic difference of tweeling, when compared with common cloth, consists in the intersections, although uniform and equidistant, being at determinate intervals, and not between the alternate threads. Hence we have specimens of tweeled cloth, where the intersections take place at the third, fourth, fifth, sixth, seventh, eighth, or sixteenth interval only. The threads thus deflecting only from a straight line at intervals, preserve more of their original direction, and a much greater quantity of materials can be combined in an equal space, than in the alternate intersection, where the tortuous deflection at every interval keeps them more asunder. On this principle tweeled cloths of three and four leaves are woven for facility of combination alone. The coarser species of ornamented cloths, known by the names of dornock and diaper, usually intersect at the fifth, or half satin interval. The sixth and seventh are rarely used, and the intersection at the eighth is distinguished by the name of satin in common, and of damask in ornamental tweeling. It will further be very obvious, that where the warp and woof cross only at every eighth interval, the two sides of the cloth will present a diversity of appearance; for on one side the longitudinal, or warp threads, will run parallel from one end of a web to the other, and on the other the threads of woof will run also parallel, but in a transverse direction across the cloth, or at right angles to the former. The points of intersection being only at every eighth interval, appear only like points; and in regular tweeling these form the appearance of diagonal lines, inclined at an angle of 45° (or nearly so) to each of the former.

The appearance therefore of a piece of common tweeled cloth is very similar to that of two thin boards glued together, with the grain of the upper piece at right angles to that of the under one. That of an ornamented piece of damask may, in the same manner, be very properly assimilated to a piece of veneering, where all the wood is of the same substance and colour, and where the figures assume a diversity of appearance from the ground, merely by the grain of the one being disposed perpendicularly to that of the other.

From this statement of the principle, it results that the most unlimited variety of figures will be produced, by constructing a loom by which every individual thread of warp may be placed either above or below the woof at every intersection; and to effect this in boundless variety, is the object of the draw loom.

Besides what has been already stated under the article Cloth Manufacture, the reader will find some details respecting the draw loom, as modified to produce ornamental figures upon double cloths, by referring to the article Carpet, where he will also find a plan and description of a draw-loom capable of being wrought by mechanical power, and adapted to those peculiarities which distinguish carpet, or double-cloth weaving, from damask or satin tweeling. In order to complete the plans for applying power to ornamental texture, he will now find in Plate CCXXVII. a perspective representation of a draw-loom adapted for damask tweeling, and which, although in some respects similar in principle to the other, possesses many distinguishing properties necessary to fit it for its immediate object. By comparing the three, he will thus be able to form a comprehensive estimate of their respective uses, and the distinctions of their construction.

Plate CCXXVII.

Fig. 1.

Fig. 1. is an oblique perspective representation of the loom, of which the following are the chief constituent parts upon which the peculiarity of construction depends. The posts and cross-sails which constitute the framing are respectively at AAAA and at *aaaa*. The yarn, or warp beam, is at B. The perforated board, or frame which regulates the harness, is at C; the frame of directing pullies is above at D; the tail of the harness is at M, and the board, or table, as weavers call it, to which its extremity is attached, is at E; the simples, or descending cords, are at L, their extremities being fixed to the floor at O. In these parts there is little difference from any ordinary draw-loom, excepting in the obliquity of the simples at L, which keeps them closely in contact with the cylinder or barrel G, by which they are moved. The heddles, which consist of eight leaves, with the long eyes common in every species of harness-work, as there is nothing peculiar in their construction, and as they must be almost entirely concealed by the harness, are entirely omitted, as are also the lay and cloth beam for the same reasons. The eight treddles, or levers, which give motion to the heddles, appear below at I, and these are moved by the revolution of the shaft S, which takes the motion from the power by a pulley and belt in the common way, and which, as it communicates the motion, either directly or indirectly, to every other part, may be regarded as the *primum mobile* of the whole engine. On the shaft S is a succession of eight wipers, or traverse wheels, which successively move all the treddles, so that woof is eight times inserted by every revolution of the shaft, the motion of which must, of course, be very slow, not exceeding at the utmost eight revolutions per minute; and if the loom be wide, even this will be found too much. The wipers are all similar, and are shaped to effect uniform reciprocating motion.

The barrel, or cylinder G, receives its motion from the shaft below, by means of the catch H, and the upright spindle L, which are moved by pins in the shaft as often as the harness is to be shifted, instead of the catch, which is drawn aside and returned by the operation of the cord K, acting by a weight at its opposite extremity. Here it may be proper to remark, that this motion may be very conveniently, simply, and cheaply effected, merely by a straight lever moving on or near its centre, one extremity of the lever being jointed to the vertical rod L, and the other projecting over a wiper fixed on the shaft S. The extremity over the shaft, whenever elevated by a protuberance on the wiper, would depress L, and move the barrel, after which it would return by its own weight to its former position, until again set in motion. The latter plan is most simple, and avoids all difficulty in fitting and disengaging the catch.

Every operation of the most complicated damask draw-loom will thus be performed without either weaver or draw-boy; and as the yarn employed in the damask manufactory, as practised at Dunfermline and other places in the east of Scotland, is very strong, little further labour would be required than that of dressing the warp, and occasional superintendance. It would be proper, indeed, to employ a boy or girl to watch the progress of every loom, as is the case in other kinds of power weaving.

It remains only to make some general remarks upon the construction of the barrel; the range of pattern which it is capable of producing in its most simple form; the means of extending that range to the most complicated designs; and to add such other miscellaneous remarks as the nature of the machinery and operation may suggest.

When the range of a draw loom pattern is very extensive, covering many designs, the number of simples must be increased proportionally, as has been shown under the article Cloth Manufacture, where no less than *three* distinct sets of *simples* and *lashes* are supposed necessary, and that these must be used successively before the whole range of an extensive pattern can be completed. Under similar circumstances, some such expedient must also be adopted in this loom, and it is not very difficult to devise one; for different sets of simples may be used in the same way; and if the pattern be too comprehensive to be included in one revolution of the barrel, without increasing its diameter to an inconvenient size, two, or even three or four, may be successively used, until the design is completed. The barrel being constructed to revolve on centres, a very few minutes only will be lost in changing a set of simples and a barrel, and as the former operation is necessary in all extensive draw looms, the other may be done at the same time by an additional person, without a moment being lost. If we suppose the barrel 2 feet diameter, as in the scale, and four feet long, it will present a circumference of 6 feet, which, allowing $\frac{1}{8}$ of an inch to each simple, will move 384 of these as required. Again, if the harness is to be lifted three inches, and we reduce the range of the barrel to one inch, by the means suggested in the description of the carpet power draw-loom, or any other which may appear preferable, we shall have 864 changes by one revolution. Perhaps one of the best and most simple ways of reducing the range of the barrel, would be to substitute levers, bent at right angles, for the pullies in the frame. If the horizontal part of the lever, to which the harness cords are attached, were, for instance, six inches, and the vertical part, which is connected with the tail cord, 2 inches, the range of the harness would be to that of the barrel in the ratio of 3 to 1, and were the perpendicular part but one inch, of 6 to 1; but we are to recollect, that, from the way in which the simples are attached to the tail, so much range is lost, that a further allowance must be made for this. There is another contrivance used for raising the harnesses of draw-looms, which is known by the name of the patent draw-loom. These have been for many years in actual practice at Dunfermline, and their principle may be very easily applied to a barrel draw-loom, worked by power. The limits of this article will not admit of a detailed description, which indeed could not be rendered intelligible without a plate. The principle consists in the use of a lever, the end of which resembles a common garden rake, or coarse comb. The harness has neither pullies, tail-cords, nor simples, but hangs vertically from the roof. The lashes pull all the cords required to be lifted into the intervals between the teeth of the comb; and every cord being furnished with a knot, immediately above the teeth, the whole are lifted at once by the operation of the lever.

Such an apparatus might possibly be found advantageous, in some instances, in the power draw-loom, and it might be very easily applied. The simples at L, and box at D, might be removed as unnecessary; the barrel placed before the table R, and the comb immediately under; the knots would be pulled between the teeth by the operation of the barrel, and the comb-lever might be worked by a wiper on the shaft S below. (J. D.)

DAMASONUM, a genus of plants of the class Hexandria, and order Hexagynia. See Botany, p. 193.

DAMIETTA, or Damiatt, is a town of Egypt, situated on the eastern bank of the Nile, and about 5 miles from its mouth. It stands upon a tongue of land, stretching about 6 miles from east to west, and bounded on one side by the river, and on the other by the western extremity of the Lake Menzale. The town, which is very large, is rounded in a semicircle, and from one end of the crescent the whole extent of it may be seen. The houses, particularly those on the banks of the river, are very high, and have commonly handsome saloons built on the tops of their terraces. The principal ornaments of the town are the squares, the chief of which has retained the name of Menchie (the original name of the town); the mosques, which are adorned with lofty minarets; the public baths, which resemble those of Cairo, and are lined with marble; the bazars, and the khans or okals, which are filled with great varieties of merchandise.

Damietta was formerly celebrated for its fine gardens, which abounded with orange groves, and produced every kind of fruit; and where the finest rice was raised in the greatest abundance. Owing, however, to the stream of the Nile having been taken to the canal of Menouf, instead of passing by Damietta, its gardens have disappeared, its rice fields are sown with wheat, and not even fresh water can be obtained. This evil, however, has been in a great measure removed by Achmet Aga, who has constructed a large vessel for bringing water to the town. It is conveyed in vast cisterns from above Fareskour, where the river has sufficient force to drive back the salt water.

In descending the river from Damietta to Lesbe, the houses on its banks have a very picturesque appearance. Stages are generally stretched across the river, on which vines are planted, and seats erected under their shade. The village of Lesbe, which is distant only a mile from the sea, was destroyed by the French, who left upon its site an unfinished fort. It has a high brick wall, without any fosse or glacis, and there are in the interior three excellent barracks; but the remains of the old houses were not carried away. Lord Valentia could not discover any of the ruins mentioned by Savary as existing in his time, and which he imagined to have been part of the ancient Damietta. He could find neither vestiges of walls, nor heaps of pottery, nor any appearance of lime and brick mingled with the soil; and even in the places through which the canal has been cut, no remains were to be seen. Achmet Aga, the governor, has erected a thriving village below

Lesbe, in which he obliges all the fishermen to reside, that they may give assistance to vessels in distress, or when wrecked on the shore. Here Lord Valentia observed a round tower of ancient masonry, which forms the extremity of a building that reaches to the river; and he is of opinion that the great iron chain which was formerly stretched across the river was fastened to this edifice.

In order to prevent a hostile fleet from entering the river, the mouth of it is choked up with a bar called Boyaz, which is not so impassable as the bar at Rosetta. It admits ships of much larger burthen than the Scherms or Jerms, which are employed in loading and unloading the ships in the road. The vessels which are able to get over the bar anchor close to the town in fourteen feet of water.

Damietta carries on a very considerable commerce with Syria, Cyprus, and Marseilles. Its principal exports are rice, of which six millions worth is annually exported, linens, sal ammoniac, and corn, the last of which is sent off under the name of rice, as its exportation is prohibited.

In the numerous villages which encircle Damietta, are fabricated the most beautiful linens, and particularly a kind of napkins fringed with silk.

There are few remains of antiquity in this town. Lord Valentia saw the ruins of an ancient granite obelisk, which is nearly worn away, and which is mentioned by Andreossi as forming the door sill of the barracks. He also found near the door of a merchant, two pedestals, one of which contained the following Latin inscription.

LICINIAE LF SECUNDAE
DOMITI CATULLI.

The other, which was partly concealed by a step, exhibited when removed the following Greak inscription.

Η ΒΟΥΛΗ ΚΑΙ Ο ΔΗΜΟΣ
ΛΟΥΚΙΟΝ ΠΟΠΙΛΛΙΟΝ ΒΑΛΒΟΝ
ΠΡΗΣΒΕΥΤΗΝ ΤΙΒΕΡΙΟΥ
ΚΛΑΥΔΙΟΥ ΚΑΙΣΑΡΟΣ
ΣΕΒΑΣΤΟΥ ΓΕΡΜΑΝΙΚΟΥ
ΤΟΝ ΠΑΤΡΟΝΑ ΤΗΣ ΠΟΛΕΟΣ.

The owner of these pedestals informed Lord Valentia, that they were brought in a vessel from Syria. Andreossi mentions a Greek inscription on a column in a mosque, which Lord Valentia copied, and of which he has given an engraving. He considers it as cabalistic. At Menchie, a suburb nearer the sea, he found an Arab inscription, which places its erection in the 1117th year of the Hegira. It contained several beautiful marble columns greatly injured, and near it was a marabout, having its dome sustained by four columns of jasper, which had preserved their polish in a remarkable manner. A fifth jasper column was placed at the entrance.

The greater number of authors who have written upon Egypt, such as Sicard, Pocock, Prospero Alpini, Shaw, Maillet, and Niebuhr, have supposed that the modern Damietta was built upon the site of the ancient town. Savary, however, is of opinion, that ancient Damietta occupied the spot on which the village of Lesbe now stands, and in proof of this, he mentions the ruins which Lord Valentia could not discover. "The mosque which Savary mentions," says Lord Valentia, "could not be the one left when the Sultan of Egypt destroyed the town, as it is of a modern date. Certainly if Savary have faithfully translated the quotations he has given from Macrizi and Abulfeda, there can be no doubt that the ancient Damietta was destroyed, in order to prevent its being taken from the Christians, and a new town of the same name was built higher up the river; yet it is difficult to comprehend what advantage would arise from removing it only a few miles to the site of the present town, or indeed for its removal at all, since the walls and fortifications alone were of importance, and their complete destruction would have precluded the possibility of its again becoming an asylum to a vanquished enemy." Population of the town 80,000. Distance from Cairo, 84 miles N. N. E. East Long. from Greenwich observatory 31° 57′, and North Lat. 31° 25′ 40″. See Savary's *Letters on Egypt,* vol. i.; Niebuhr's *Travels in Arabia,* vol. i.; and Lord Valentia's *Voyages and Travels to India, Egypt, &c.* vol. iii. p. 416—421. (π)

DANNEMORA, the name of the most celebrated iron mine in Sweden, is situated in the province of Upland, about one English mile from Osterby, and 30 English miles north of Upsal. This mine was discovered in the year 1448, and though it has been now wrought for nearly 366 years, it still yields abundance of the best iron in Europe. It was originally wrought as a silver mine, the silver being found in the galena; but when this became unproductive, the attention of the proprietors was directed exclusively to its iron ore. At first it belonged to the King of Sweden, but that monarch consigned it to the Archbishop of Upsala as a part of his revenues; and it now belongs to a number of private individuals, each of whom works it separately on his own account.

The iron mine is on a hill, which has scarcely the appearance of being elevated above the surrounding country. It is about two English miles long, and nearly half a mile broad, and is encircled by lakes, those of Dannemora, Films, and Grufve being quite close to it. On the side where there are no lakes, there is a turf moss. The ore forms a large vein in this hill, which stretches in a north-west and south-east direction. The mine was some years ago inundated by the water from the adjacent lakes. A strong wall, however, has been built to keep off the water. It is drained by means of two steam-engines, kept going by means of wood for fuel.

At the side of the mine is a large opening, about 50 fathoms deep and 50 wide, and at the lower part of this is the entrance to the mine, which is wrought about 30 fathoms deeper than this opening. The ore is blasted by gunpowder. The part of the vein at the mouth of the mine is called *stor rymning*; the next portion, called *jord grufva,* earth mine, yields the finest ore; and the portion farthest south, called *sodra grufva,* or southern mine, yields the worst ore, probably from being mixed with galena and blende. The rock through which the vein runs is said to be quartz. The substance immediately contiguous to the vein appeared to Dr Thomson to be hornstone, and to contain hornblende. The ore itself contains limestone, quartz, and actinolite, and affords from 25 to 75 per cent. of cast iron. In the worst kind of ore, Dr Thomson also perceived blende, fluor spar, galena, and amethyst, but in small quantities.

Dante. Carbonate of lime, crystallized in dodecahedrons, also occurs in this vein; and likewise sulphate of barytes, mountain cork, and the aplome of Hauy.

After the ore is broken into small pieces and roasted, it is put into conical-shaped furnaces constructed of the slag from cast iron. In these furnaces it is mixed with the proper quantity of charcoal, and then melted and separated from the slag. The cast iron obtained in that manner is as white as silver, completely crystallized, and very brittle. This cast iron is reduced to malleable iron, by heating it in a bed of charcoal, and hammering it out into bars. In this state it is whiter than common iron, is less liable to rust, is distinctly fibrous in its texture, and much stouter than any other iron.

The quantity of iron yielded by this mine every year, amounts to above 4000 tons; it is all sent to England, the greater part of it being purchased by a merchant in Hull. It is all converted into steel, and may be known by a mark of three balls.

Some chemists ascribe the superiority of the Dannemora iron to the presence of manganese. Berzelius attributes it to the presence of the metal of silica, while others, with more reason, suppose it to arise from the nature of the process employed. In the neighbourhood of the mines are establishments for forging the iron, and for the accommodation of more than 300 workmen with their families. Each of the little villages has three or four regular streets, often planted with trees, a church, a school, and an hospital. See Coxe's *Travels*. Catteau, *Voyage en Allemagne et en Suede*, tom. ii. p. 292; but particularly Dr Thomson's *Travels in Sweden during the Autumn* of 1812, chap. x. p. 186—192, to which we have been indebted for the greater part of the preceding information. (π)

DANTE, Alighieri, one of the earliest and most celebrated poets of modern Italy, was born of an illustrious family at Florence, in the year 1265. At a very early age he displayed genius of a superior order, and applied himself successfully to the study of philosophy and literature, under the tuition of Brunetto Latini. When grown up to manhood, he eagerly engaged in the business of public life, and raised himself by his abilities, to an eminent rank amongst his fellow citizens of the republic of Florence. He appears to have commenced his public career in the military profession; in which he acquired considerable reputation; having distinguished himself, by his bravery, in the battle of Campaldino, or Arezzo, where the Florentines obtained a signal victory. In the year 1291, he espoused Gemma, the daughter of Manetto de Donati, a lady whose disposition was by no means calculated to contribute to his domestic happiness and comfort; and from whom he separated after she had brought him several children.

The superior talents and acquirements of Dante soon paved the way for his advancement to the highest honours of the state. In the year 1300, he was appointed one of the chief magistrates of the Florentine republic; a situation, however, which, at that troublesome period, exposed him to many dangers, and eventually proved the occasion of his ruin. Italy was, at that time, kept in a state of continual agitation by the opposite factions of the *Guelphs* and *Ghibellines*, which were the cause of so much animosity and bloodshed; and the city of Florence was, moreover, distracted by the turbulent parties of the *Neri* and *Bianchi*, or Blacks and Whites; a distinction originating from a private quarrel between the two noble families of the *Cherchi* and *Donati*. Dante unfortunately embraced the cause of the White faction, and his party having been ultimately overpowered, sentence of banishment was pronounced against him, his possessions were confiscated, and his house razed to the foundation. Dante.

At the time these proceedings took place, Dante was absent from Florence. But the news of the sentence reached him at Sienna, on his return; and seeing himself there surrounded by a numerous and illustrious band of exiles, he associated with them, and, under the conduct of Alessandro di Romena, this army made repeated attempts, during a period of four years, to regain possession of their native city. All these attempts, however, proved unsuccessful; and the band of exiles, at length, seeing their hopes frustrated, dispersed. Dante repaired to the court of Verona, where he found a patron in the great *Cane de la Scala*, Prince of Verona, whom the poet has celebrated in the first Canto of the *Inferno*. But his residence there was short; the treatment which he experienced at the Veronese court did not accord with his talents and temperament; and he found it necessary to seek his fortune elsewhere. From Verona, therefore, he retired to France; where he endeavoured to attract the notice of the learned; and, as Boccacio informs us, disputed with great reputation in the theological schools of Paris.

In the year 1308, Henry, Count of Luxemburgh, was elevated to the imperial dignity; and Dante seems to have conceived the hope of being restored to his native city, through the influence and exertions of that prince. Accordingly he attached himself to the interests of the new emperor, and endeavoured to conciliate his favour, it is supposed, by the composition of his Latin work *De Monarchia*, in which he asserted the rights of the empire against the encroachments of the papacy. In the year 1311, the emperor laid siege to Florence, but was baffled in his attempt to take the city; and his death, which happened in 1313, deprived Dante of all hopes of re-establishment in his native country.

For some time after this period, we have no certain accounts of the circumstances of his life; but he is supposed to have wandered about Italy, for several years, in a state of poverty and dependence; until at length, through the friendship and patronage of Guido Novello de Polenta, he procured an honourable establishment at Ravenna; where he continued to reside during the few remaining years of his life. In the service of this new patron, he was employed, as ambassador, to negociate a peace with the Venetians, who were making preparations for hostilities against Ravenna. On his arrival at Venice, however, he was unable to procure a public audience; and the fatigue of the journey, together with the mortification he experienced from the ill success of his mission, threw him into a fever, which terminated in his death, on the 14th of September 1321, in the 57th year of his age. His remains were magnificently interred by Guido; who also took upon himself the office of pronouncing the funeral oration, and, at the same time, expressed his intention of erecting a splendid monument to the deceased; an intention which his own subsequent misfortunes deprived him of the power of executing. This honourable task was afterwards performed by Bernard Bembo, the father of the celebrated cardinal, who raised a handsome monument, with a suitable inscription, over the neglected ashes of the poet.

The Florentines, as if to expiate their resentment against the illustrious poet, whom they had so unrelentingly persecuted when alive, made repeated fruitless attempts to recover his bones from the city of Ravenna. In the age of Leo X they made a solemn application to the Pope for that purpose; and the celebrated Michael

Angelo, an enthusiastic admirer of Dante, generously offered to execute a magnificent monument to the memory of the poet. But this application was likewise unsuccessful. To evince, however, the very high estimation in which his talents were held in his native city, the republic of Florence, in the year 1373, assigned a public stipend to a person appointed to read lectures on the *Divina Commedia;* and the first individual engaged in this office was the celebrated Boccacio. A sumptuous monument was raised to the memory of Dante, in 1780, by the legate Cardinal Gonzaga, bearing the inscription: "*Danti Aligherio, poetæ sui temporis primo, Restitutori politioris humanitatis.*" A few years ago, we were informed by some of the literary journals, that a subscription had been opened at Florence, for defraying the expence of a public monument proposed to be erected in honour of their great native poet; and that a drawing of the intended structure had been submitted to the Florentine Academy of the Fine Arts, which met with general approbation. We are ignorant whether the intended monument has been since executed.

Boccacio describes Dante as a man of middle stature; his demeanour was solemn, and his walk slow; his dress suitable to his rank and age; his visage long, his nose aquiline, his eyes full, his cheek bones large, and his upper lip projecting over the under one. His complexion was olive; his hair and beard thick and curled. His manners were grave and sedate; his deportment, in public and private life, was regular and exemplary; and he was extremely temperate in his way of living.

Dante is the author of several works, both in prose and in verse; but his fame now rests entirely on his great poem, the *Divina Commedia.* At what period, and in what place, he composed this singular poem, has not been precisely ascertained by any of his numerous commentators. Boccacio affirms that he began it in his thirty-eighth year, and had finished seven cantos of the *Inferno* previous to his exile from Florence. The beginning of the poem is said to have been fortunately preserved from the wreck of his effects; and being afterwards restored to the poet, he was induced to continue it, amidst all the embarrassments of an unfortunate and agitated life. At what time he completed it is equally uncertain; but it was probably finished during his residence at Verona, as he dedicated the *Paradiso* to his Veronese patron.

When we take into consideration the various disadvantages under which this poem was composed,—whether resulting from the private circumstances of the poet, or from the general complexion of the times in which he flourished; we shall find sufficient reason to admire the genius that was capable of producing such a work, at an æra by no means favourable to the developement of poetical talents. Before Dante appeared, very little progress had been made in the cultivation of the vulgar dialect of Italy, as a learned or poetical language. At that period, the studies of literary men were almost exclusively devoted to the dialectics of the peripatetic philosophy, and the sophisms of polemical science. The ancient models of polite literature had scarcely yet exerted their influence in purifying corrupted taste, restraining the license of ungoverned imagination, and conducting the efforts of genius to the more cultivated regions of poetical fancy. On the accession of Charles of Anjou to the throne of Naples, that restless prince made some small compensation for the animosities, which he introduced or fostered among his subjects and neighbours, by transporting the *Provençal* poetry from France to Italy. Upon the wild, but often spirited compositions of the French *Troubadours,* the genius of the first Italian poets appears to have been formed; and it is not improbable that from these productions Dante may have caught some of the earliest sparks of that poetical flame, which afterwards shone forth with such lustre, in the *Divina Commedia.*

In this extraordinary production, the author is conducted in a vision, through hell, purgatory, and paradise; which gives occasion to the tripartite division of the poem. Although Dante is generally classed among the epic poets, the *Divina Commedia* displays more of the didactic, than of the epic character. Hell, purgatory, and paradise, are employed by the poet as so many theatres for the exhibition of a variety of characters of all ages and conditions; the poem, in the midst of much occasional extravagance, abounds in the most sublime images and sentiments; and there are few works of genius which display a more intimate knowledge of the human soul, or contain a more ample store of the most useful precepts and practical maxims for the conduct of life. The works of Dante have been accused of obscurity and harshness. These scrictures must be meant to apply either to the matter, or to the style, or to both. With regard to the first, great allowance ought to be made for the prepossession of the age in favour of scholastic learning, to which every author, who aspired to reputation, was, in some measure, forced to accommodate himself; and, in the second place, it must be remembered, that many forms of expression had, through the influence of time, and the neglect of succeeding writers, become obsolete, which, in the age of Dante, were in current use. The lyrical poems of Dante are, in the opinion of Muratori, no less worthy of estimation than his larger work.

There are numerous editions of the *Divina Commedia;* that which was published at Venice, 1757, in three vols. 4to, is esteemed the best. Dante had three sons, each of whom wrote a commentary on their father's poem. The *Divina Commedia* has been translated into English verse by the Rev. Henry Boyd, with notes and illustrations, London, 1802, in three vols. 8vo. See the Life prefixed to Mr Boyd's translation of Dante; also *Gen. Biog.* Muratori *Storia della ling. Ital.* The reader will likewise find some particulars relative to Dante in the Notes to Hayley's *Essay on Epic Poetry.* (*z*)

DANTHONIA, a genus of plants of the class Triandria, and order Digynia. See BOTANY, p. 114.

DANTZIC, GDANTZK, or DANTZIG, the *Gedanum* of the ancients, is a large city of Polish Prussia, in the palatinate of Pomerellia, or Little Pomerania. It is situated about four miles from the embouchure of the Vistula, and on one of the branches of that river, which form the island called the Dantziger Werder.

Dantzic is divided into three towns, the Fore Town or Vorstadt; the Old Town or Altstadt; and the Rechtstadt. The suburbs, the greater part of which were burnt during the siege in 1806, had the names of Old and New Scotland, Stoltzenberg, Hagelberg, Bischofsberg, Schidlitz, and Langefuhr. The suburbs of Old and New Scotland were formerly inhabited by Scotch families, who had settled in the town, on account of particular privileges having been granted to them, in consequence of services rendered to the city by a Scotch family of the name of Douglas. The suburb of Stoltzenberg stands on a sandy hill, and commands a fine prospect of the town and harbour. The Radaune and the Motlau, two small rivers, run through the city. The houses in Dantzic are built of brick and stone, and are commonly three or four stories high. On the outside of the ground floor there is a kind of gallery called *Beyschlag*, which projects into the street, and in the middle of which is the chief entrance. The principal public buildings are the cathedral; the building which was formerly the college of the Jesuits; the Lutheran college; the Hotel de Ville; the Court of the Nobles; the Junker-Hof, or the Court of Artus; the church of St Catherine and the tomb of Hevelius; the mill upon the Radaune; the gate of the Lang-gasse, and the green gate. The chief curiosities in the cathedral, which is one of the finest churches in Europe, are the organ, the baptistery, and the picture of the last judgment: The hotel de ville is a handsome building, and has a library and a cabinet of painting, in which are the original manuscripts of the *Selenographie,* and the *Machina Celestis* of Hevelius. The arsenal contains the marble monument which Sigismond had carried to be sculptured in Italy in honour of his father the king of Sweden; and the Junkerhof, which is the place of exchange, contains a marble statue of Augustus III.

The principal literary establishments are the Gymnasium, the Physical Society, and the Society for the promotion of Commerce. The library of the Gymnasium possesses about 30,000 volumes. The Physical Society has an excellent zoological and mineralogical collection. The Cabinet of Curiosities belonging to Scheffler, contains more than 4000 masses of yellow amber. The library of the church of St John is also worthy of notice. Besides the public buildings which have been mentioned, Dantzic contains seven Lutheran churches, two belonging to Calvinists, and one Roman Catholic chapel.

The public granaries, which consist of a great many buildings four or five stories high, form a separate town, called Speicher Island, encompassed by water, and communicating with the city by a draw-bridge. A number of fierce mastiffs are kept for the defence of the granaries, and are let loose at 10 or 11 o'clock at night.

The harbour of Dantzic is very large, and there is a good canal which communicates with the Motlau, and is very convenient for the transportation of merchandize. It is defended by a fortress at Weichselmunde, and there is a lofty tower which serves for a light-house. Ships which draw more than eight feet of water cannot enter the canal which leads from the Vistula to the city; but their cargoes are conveyed in barks called *bordings*.

Dantzic has long been regarded as one of the principal granaries of Europe. The corn received from Poland, which is annually exported from Dantzic, is computed at 730,000 tons, or 365,000 lasts. It is brought from Poland in sloops of from 30 to 60 tons, which bring also the other productions of Poland, namely, potash, flax, wax, masts, wood for shipbuilding, staves, superior to those of Hamburgh. Poland in return draws from Dantzic about 2000 tons of Swedish iron annually; articles of Indian manufacture, linen cloth, silks, brandy, and wines. The principal exports from Dantzic are the masts of ships, cork wood, hemp and flax, potash (called the alkali of Dantzic), honey, wax, tallow, steel, iron, copper, lead, saltpetre, tar, amber, skins, furs, wool, and salt from Poland. In the year 1788, the following estimate was made of its commerce. The 60,000 lasts of corn which came from Poland amounted, at 18 ducats per last, to about 2,080,000 ducats. The other articles, as wood, potash, linens, skins, honey, &c. which came from Poland, amounted to nearly the same sum; so that there was an annual capital of 6,000,000 rix-dollars vested in commerce. The profit upon this sum amounted to about 1,200,000 rix-dollars, from which deducting 150,000 for taxes, custom-house dues, and the interest of money, there is left 900,000 rix-dollars for the annual profit upon their commerce.

In some particular years the trade of this city was so great that the barks and vessels which came down the Vistula from Poland and Prussia, amounted to 1288, and the ships which arrived and cleared out of its harbour were 1054. In 1802, 1674 ships entered Dantzic, and 1916 cleared out. The following is a list of them.

	Arrived.	Cleared out.		Arrived.	Cleared out.

In 1806, however, the number of ships that arrived was only 377, and those that cleared out 408.

The following are the principal articles which were manufactured in Dantzic, woollen stuffs, cloths, gold and silver stuffs, lace, ribbands, white and black soap, starch, gunpowder, paper, cutlery goods, tobacco, saltpetre, Morocco leather of all colours, shoes and slippers; red and yellow boots for children; tanned leather; varnish made of amber, gum sandarach and oil; musical instruments; furs which are dyed in a very superior manner; different liqueurs, and a kind of spruce beer known in England by the name of black beer. The total amount of the manufactures of Dantzic in 1804, was 774,569 German crowns, one of which is equal to 3 francs.

Among the objects which are deserving of notice in the environs of Dantzic, we may mention the Abbey of Oliva, celebrated by the peace which was concluded there in 1660. The apartment and the table where the act was signed are still to be seen; and this great event is recorded on a tablet of marble. The chapel of the Virgin, and that of the Abbé Rybinsky, in the form of an ancient round temple, are greatly admired.

Although more than 40,000 of the inhabitants of Dantzic were carried off by the plague in 1709, yet in 1730, the population was reckoned to be 200,000. In 1752 the number of deaths are stated at 1846 by Busching, which calculating at 1 in 50, gives a population of 92,300. In 1774, the population was estimated at 50,000. In 1783, the number of births was 1118, and the deaths 1683, which gives a population of 84,150, reckoning at the rate of 1 in 50. In 1802, the population was 47,000, exclusive of the garrison. In 1804, it was reckoned at 60,097, including the garrison.

The various political revolutions which this city has sustained will be related in another part of our work. In 1806, when it was besieged by the French under Marshal Lefebvre, the whole of the suburbs were burned down, and 3000 buildings considerably damaged. The loss on this occasion was estimated at one million and a half sterling. During the siege which it underwent during the last year (1813) from the allied army, it has also received very considerable injury; and even if the independence of Europe and the freedom of commerce are completely established, a series of years must elapse before Dantzic recovers from the severe losses which have been so cruelly inflicted upon her. East Long. by astronomical observations, 18° 38′ 30″, North Lat. 54° 20′ 48″. (π)

DANUBE, or DONAU, is the greatest river in Germany, whether we consider its length, its depth, or its width, and is the largest of all the rivers in Europe except the Wolga. Without counting its windings, the length of its course has been calculated at 1620 miles. The Danube has its origin near the small town of Doneschingen, or Donaueschingen, in Suabia, in the court-yard of the palace of the princes of Furstenberg. Some small rills of water spring from the ground, and form a basin of water about 30 feet square, from which issues a brook, that afterwards falls into the united rivers of Bribach and Brege.* After passing by the towns of Ulm, Newburg, Ratisbon, Straubing, Passau, Linz, Crems, Vienna, Presburg, Buda, Belgrade, and Widdin, the Danube discharges itself, by several mouths, into the Black Sea, in the province of Bessarabia.

From several towns on the Danube, but particularly from Ulm and Ratisbon, there set out, every Sunday, a number of boats, which convey goods and passengers to Vienna. At Ratisbon, there are 16 or 17 licensed proprietors of boats, who perform this duty in rotation.

From its source, till it reaches Ratisbon, the Danube runs in a north-easterly direction. After having quitted the vineyard and fields of Ratisbon, and the beautiful ruins of Donaustauff, the boat generally casts anchor near Pforter, opposite to Worth. The next morning it passes the bridge of Straubing, which is reckoned the most dangerous part of the voyage. The church near Poyen seems as if it were about to fall upon the heads of the passengers, and the small islands which here occur, and the gloomy forests of pine, give a new character to the landscape. The banks of the river rise like an amphitheatre, till the ruins of the castle of Natternberg come in sight. At Deckendorff the Danube receives the waters of the Iser, and at Vilshofen it is crossed by a wooden bridge of 16 arches, and is joined by the Vils, famous for its trouts and salmon. The Danube now assumes a melancholy and picturesque character, which continues till it reaches Passau. The windings of its course are constantly interrupted by rocks, both above and below the surface, which occasion a great noise, and require all the skill of the pilot to avoid them. Passau is situated upon an isthmus, formed by the Danube and the Inn, which now discharges its water into the former. The Inn is about 100 feet broader than the Danube at their confluence,† and from this cause the Swiss writers have contended that the Inn is the finest river, and consequently that the Danube has its origin in Switzerland. Here is a splendid view from the citadel of Passau, and the town is celebrated for having afforded to Salvator Rosa some of the finest subjects for his pencil. The Danube now becomes more rapid, and, for a considerable distance below Passau, its banks are high hills and rocks covered with box-wood and spruce fir.

Behind Passau, the Danube forms some delightful little islands. The small villa of Krempenstein has a picturesque situation upon the summit of a mountain; and, in turning from the north to the south, a sudden view is obtained of the chateau of Furstenstein, on a height upon the right bank. The boat now passes at the foot of a rock adorned with a small chapel, which forms the frontier between the territory of Passau and that of Austria. Hafnerzell, as its name imports, is inhabited only by potters, who supply several countries with crucibles of black lead, and even export them to the Indies. At a considerable distance on the left is seen a fine old tower, not far from Engelhardzell or Ingelhartzeil. At this town is the first Austrian custom-house, where a rigorous examination of the boats takes place. The two remarkable chateaus of Reinach and Marsbach are deserving of notice, and on the left is an insulated dungeon, celebrated in the romances of Mrs Radcliffe. The situation of Neuhaus and Aschau are greatly admired. Towards Linz, the Danube runs almost due east, through a flat country, with high mountains in the distance, clothed with wood. The beautiful situation of Linz; its fine bridge of 20 wide arches; the magnificent church of Bostelfeld, the appearance of Ufer-Linz; the vineyards; the cultivated fields; the alps of Salzbourg, in the distance, covered with snow, form a spectacle which is reckoned one of the finest in Europe. The beautiful town of Ens now appears on the right hand, and the rivers Trauen and Ens throw themselves into the Danube. The course of the river is now very irregular, and sometimes winds to the south, and at other times to the north-east. Sometimes it resembles a sea, with scarcely any land in sight, and at other times it is broken into small streams by numerous islands. The ruins of Speilberg attract the traveller's notice, and after having passed the beautiful chateau of Waldsee, that of Greyn next appears, wildly situated upon rugged rocks. The noise of the breakers at its foot has procured for it the name of Greynes-Schwall. A dreadful noise, like that of thunder, soon announces the famous waterfall and whirlpool of Stroudel. It has frequently proved fatal to boats drawn into its vortex; but if the boatmen are not intoxicated, and the water is not too low, there is no risk of any accident. This whirlpool is produced by a rugged island of rock, which rises in the middle of the river. The boats pass to the left of this island, above a rocky bottom, and where the rocks and heaps of stones raise themselves out of the water. The Empress Maria Theresa expended considerable sums of money in improving the navigation of this part of the Danube. About a quarter of a league farther is the whirlpool of Wirbel, still more dangerous. The impetuous waves of the Danube, which here dash against an inclined promontory of rock, are driven back in rapid circles across the narrow strait confined between two lofty banks. Before they enter, and after they quit these two whirlpools, the boatmen regularly say their prayers.

The small village of Ins, the chateau of Besenberg, and another chateau in ruins, form a picturesque triangle. Maria Taferl, who drew more than 10,000 foreign pilgrims annually, crowns the summit of an insulated rock. The Abbey of Melk has a grand appearance, with its towers and walls; and beyond this place, the country grows more and more wild. A natural wall of rocks, called the *Devil's Wall,* prevents the sun from being seen; and above this wall are situated Spietz, and its rich vineyards, one of which, under the name of Spitzam Platz, produces annually a thousand muids of wine. The traveller now approaches the superb and romantic ruins of the chateau of Thierstein, the prison of Richard Cœur de Lion, the brave king of England. At the sight of this the boatmen cry out *O Richard! O mon Roi!* and bless the memory of his faithful servant. Above the chateau there is a large convent. At Stein, which is on the left of the river, there is a wooden bridge of 25 wide arches. Behind the town of Mautern appears, upon a high mountain, the vast abbey of Gottwich, celebrated for its fine buildings, its ancient manuscripts, and the learning and hospitality of its monks. Kloster-Neuburg next appears, and

* M. Nicolai maintains that the Danube has its origin at Saint-Georgen, a convent and manufacturing town in the Black Forest.

† The breadth of the Inn is here 890 feet, and that of the Danube only 780.

Daphne ‖ Dar-fur.

the mountain of Leopoldsperg, from which there is a splendid view of Vienna in all its extent. The passengers land at Nussdorff, where there is a custom-house.

After passing Vienna, the Danube flows to the south-east, forming an immense number of islands, one of which, the island of Lobau, is famous for the scene of the bloody battles which terminated the coalition of 1809. The Danube then passes Presburg, and enters Hungary below the town of Haimburg. Its course is a little to the south-east from Presburg to Comorn; but it afterwards runs almost due east to Waitxen, beyond which it runs directly south nearly to its junction with the Drave. It then moves in a south-east direction towards Belgrade, Semendria, and Widdin. After resuming its easterly course, it forms the limits between Wallachia and Bulgaria, and at last discharges itself by several channels into the Black Sea. Between Buda and Belgrade it is so deep, that it could be navigated by men of war; but on account of the cataracts, it is not navigable to the Black Sea.

The water of the Danube is generally of a yellow and clayey colour, and is impregnated with argillaceous particles. It contains a great number of different species of fish, which become very fat and delicate, from the quantity of plants and seeds which are brought down by the mountain torrents.

For fuller details respecting the subject of the Danube, the reader may consult the following books: *L'Antiquaire du Danube*, an old work; Hess *Voyages en Allemagne*, tom. iii.; Arndt *Beuchstücke aus einer Reiss nach Wien*, vol. i. Leipzig, 1801; but particularly *Donau-Reise von Regensburg bis Wien, mit Angabe aller Ortschaften und ihrer Merkwurdigkeiten.* Ratisbon, 1802. (π)

DAPHNE, a genus of plants of the class Monandria, and order Monogynia. See Botany, p. 203.

DARDANA, or the town of the Dardanelles, is a town of Turkey, in the province of Romelia, situated at the foot of the castle of the Dardanelles. It is about a mile and a half in circuit. Cotton stuffs are manufactured here, and also sail-cloth. A kind of earthen ware is made in great quantities, to the amount of 16,000 crowns annually. Small vessels are built here, and wax, oil, cotton and wine are exported. Dr Clarke informs us, that in the recess of a small bay, before reaching the town, is the best situation for viewing the part of the strait, where Xerxes is supposed to have passed with his armies; and from this place the two castles have a very striking appearance. The wine of the Dardanelles, which is of a red colour like that of Tenedos, is preferable to the latter, and keeps to a great age; and after being kept 20 or 30 years, it loses its colour but not its strength. It is called the *Vino della Lege*, and is made chiefly by Jews. It is sent to Constantinople, Smyrna, Aleppo, and even to England. Its price is about two-pence a bottle. In 1766, this town received great injury from an earthquake. The number of houses is 1200, among which 200 are Greek, 100 Armenian, and 50 Jewish. East Long. of the old castle 26° 19′ 30″, N. Lat. 40° 9′. See Clarke's *Travels*, vol. ii. p. 64. (*w*)

DAR-FUR,* a country in the interior of Africa, and situated toward the east of what is generally called the central division of that quarter of the globe, extends from 11° to 15° 0′ N. Lat. and from 25° 40′ to 29° 20′ E. Long. The people of this country possess no written documents; and little dependence can be placed upon what they relate of their early history. The people of Dageou, a country more towards the west, and who are said to have come from the vicinity of Tunis, conquered the country now called Fûr, but were at length exhausted by intestine wars. The present race of kings then succeeded, supposed to have been of Moorish origin, and to have been driven from the north by the Arabs. Some of the earlier princes are still spoken of by the names Solyman, Mohammed, &c.; but very contradictory accounts are given of the genealogy and succession of the different monarchs. The reign of Solyman is commonly mentioned as the æra, when Islamism was introduced into the country; and Mr Browne is inclined to place the reign of that prince between the years 1650 and 1680.

Government.

The monarch is completely despotic; and has no council to controul or assist him in his office. He considers the soil and its productions as his personal property, and the people as his slaves. He has no restraint but the Koran, though, in cases of extreme oppression, the Fûkkara, or ecclesiastics, express their disapprobation sometimes with considerable boldness, but they possess no regular authority, and the prince fears nothing so much as any alienation in the minds of the soldiery. In the provinces, his power is delegated to officers generally called Meleks, who possess an authority equally arbitrary. If a province has been recently conquered, or annexed to the kingdom, the chief is permitted to retain the title of Sultan, but owes his appointment and renders tribute to the Sultan of Fûr. The crown is properly hereditary, descending to the oldest son, or in default of heirs male, to the oldest brother of the deceased monarch; but this received rule of succession is frequently set aside, and the strongest claimant becomes the sovereign. In this manner Abd-el-rachman had gained possession of the supreme power in the year 1787; but in 1795, when Mr Browne penetrated into his dominions, his severe regulations and personal avarice had excited the discontent of his subjects, and particularly of the soldiery, to such a degree, as threatened a speedy termination to his reign. When the sovereign appears in public, all the spectators, as he passes, are obliged to be barefooted, to fall on their knees, and if they are his subjects, to bow themselves to the earth. Even the Meleks, when they approach the throne, are required to creep on their hands and knees. On a great day of public audience, described by Mr Browne, the king was seated on his throne under a lofty canopy composed of various Syrian and Indian stuffs of different patterns, hung loosely on a light frame of wood. The Meleks were seated at some distance on the right and left, and behind them a line of guards, with a small piece of copper, and a black ostrich feather in the front of their caps, a spear in the right hand, and a target of the hide of the hippopotamus on the opposite arm, while their dress consisted only of a cotton shirt of the manufacture of the country. Behind the throne were 14 or 15 eunuchs, splendidly but clumsily clothed in habiliments of cloth or silk; and the space in front was filled with petitioners and spectators to the number of more than fifteen hundred. A band of hired encomiasts stood on the monarch's left hand, crying out, as loud as possible, during the whole ceremony; "See the buffalo, the offspring of a buffalo, a bull of bulls, the elephant of superior strength, the powerful Sultan Abd-el-rachmân-el-rashed! May God prolong thy life! O! Master—may God assist thee and render thee victorious!"

Religion.

The religion of the country is that of Mahomet, and,

* *Dar*, signifies a kingdom or district and *Fûr*, a deer, a name supposed to have been given to the natives by the Mahomedan conquerors, indicating the rapidity of their flight.

Dar-fur.

next in rank to those who fill the offices of government, are the Faquis or learned men, that is, the priests. Some of them have been educated at Cairo, but the great part, in the schools of their own country, and are ignorant of every thing except the Koran. The whole nation, like most of the people in the north of Africa, except the Egyptians, is of the sect of the Imam Malek, and are remarkably intolerant towards the Franks. Many idols are still worshipped by the women in the Sultan's haram; and the mountaineers offer sacrifices to the deities of the mountains when they are in want of rain. At the great annual festival, they are said to practise many superstitions, and even to put to death a boy and girl as a sacrifice.

Revenues.

The revenues of the sovereign of Dar-fûr are derived from a variety of sources, which altogether produce a very great amount. On all merchandise imported, he receives a duty of nearly one-tenth; upon the slaves exported, there is demanded a kind of tax, or rather douceur, as the price of exemption from scrutiny, generally at the rate of more than L. 100 for every thousand of slaves. He receives also one-tenth of all the slaves which are procured by predatory excursions from the neighbouring districts by his own subjects. Every village pays annually a certain sum in corn; and he is entitled to the tenth of the sheep, goats, oxen, and camels, and to all the male horses, which are reared by his tributary Arab subjects. All fines for misdemeanours, which the prince himself has the power of imposing, go to the royal treasury; and every person who engages in a judicial proceeding before him, must offer a present according to his rank and property. A considerable income arises from the presents daily received from all the great personages of the kingdom, from the merchants who come to the country for purposes of traffic, and from those who solicit offices under government; and particularly at the great festival called *the leathering of the kettle drum*, there is a general offering of presents to the sovereign from all the principal people, and almost every householder in every town and village of the kingdom, on which occasion a Melek has been known to give to the value of L. 200 sterling. In addition to all these sources of wealth, the sovereign possesses lands of his own, cultivated by his slaves, for the supply of his household; and is also the chief merchant in the country, sending quantities of his own goods with every caravan to Egypt, and employing his slaves to trade in the adjacent countries with the merchandise brought from that country.

Commerce.

The principal trade of Dar-fûr is carried on with the country of Egypt, by means of a caravan to Grand Cairo. The motions of this caravan are extremely uncertain; sometimes two or more of them arriving in Egypt in the course of the same year, and sometimes none appearing for the space of two or three years. This irregularity is owing to the changes in the governments of the two countries, the caprices of their sovereigns, and the power of the Arabs who infest the roads. Hence the departure of a caravan from Dar-fûr forms a very important event; engages the attention of the whole country for a considerable time, and becomes even a kind of chronological epocha. Two thousand camels, and a thousand head of slaves, are accounted a large caravan, from Dar-fûr to Egypt; but on their return they seldom amount to five hundred camels. The principal articles transported in these caravans are slaves, camels, ivory, ostrich feathers, gum, pimento, tamarinds, leather sacks, parroquets, guinea fowls, and white copper. The principal commodities brought back from Egypt are cotton cloths made in that country, Indian muslins and cottons, light French cloths, red caps of Barbary manufacture, silks, carpets, shoes of red leather, firearms, strait sword blades, copper, tin, brass and iron wire, writing-paper, soap of Syria, small looking-glasses, beads of various kinds, coffee, spices, and perfumes.

Agriculture.

During seven or eight months of the year, the face of the country is dry and sterile; but the rainy season, which prevails from the middle of June to the middle of September, suddenly invests the fields with a delightful verdure; and in general, the produce of the year depends upon the abundance of rain which falls during this period. The south-east wind brings the greatest quantity; the north and north-west breezes are cool and refreshing; the thick, hot, and sultry air comes from the south. A custom similar to what Herodotus relates of the ancient Egyptian kings, and to what is to this day practised in the empire of China, is observed by the Sultan of Darfûr, in honour of the labours of agriculture. As soon as the wet season commences, he goes out with his Meleks and attendants, and begins the labours of the field, by planting a few grains with his own hand. Few instruments are required in the operations of their husbandry. When the soil has been sufficiently softened by the rains, the cultivator and his assistants go out to the field with a kind of hoe; and, having made small holes with this instrument over all the ground, about two feet distant from each other, throw in the grain, and cover it with the foot. The general crop consists of millet, with a small quantity of wheat, sesamum, and a particular species of bean. In two months the millet, and in three the wheat is ready for the reaper. The process in harvest is equally simple with that of the seed-time. The women and slaves break off the ears with their hands, (leaving the straw to be afterwards removed,) and carry them away in baskets upon their heads. When these have been thrashed, (which is very awkwardly and incompletely done,) the grain is exposed to the sun till it become quite dry; and is then deposited in a hole made in the earth by way of granary, and covered over with chaff and earth. In the gardens are cultivated lentils, kidney beans, onions, garlick, melons, and cucumbers. Gourds and water melons grow wild in considerable abundance. There are few trees in the country, and those, which prevail most, are characterised by sharp thorns, and a solid imperishable fibre. The plane and sycamore sometimes appear; but they are both supposed to have been brought from Egypt. The tamarind grows to a considerable size, and bears large crops of fruit. The date trees are very rare, and their fruit dry and diminutive. There are several small shrubs, some of which yield fruit scarcely worth gathering. Rice grows wild in some of the districts, but is of a very inferior quality, and is little used or esteemed. Tobacco is produced in abundance, and appears to be of native growth. Hemp is regularly cultivated, but is chiefly used as a narcotic and an aphrodisiac; and for this purpose is smoked or chewed in its crude state. Cayenne pepper is extremely common in one part of the country, and is generally used in the food of the natives.

Animals.

There are few *horses* in the country, and the natives pay little attention to the breed. Their best horses are bred in the country of Dongola, and by the Arabs to the east of the Nile. These are larger than the Egyptian breed, well formed, full of spirit, yet extremely tractable. The *asses* are similar to those of Great Britain, and are much used for riding, as few persons but the military, and those who are in immediate attendance at court, make use of horses. The only good asses are those which the merchants bring from Egypt; and one of these will sell at the value of one, two, or three slaves, according to the weight which he is able to bear. Numbers of *horned cattle* are reared in the vicinity of the rivers, and the beef, which is a constant article of food with the natives, is of good quality. Cows are numerous, but their milk is not palatable. The *camels* are of a very mixed breed, and are found of all colours and sizes. Those which are reared in the country of Dar-fur are remarkable for enduring thirst, but not capable of bearing great burthens. They are particularly subject to the mange, especially in winter; and their chief remedy is a kind of tar, procured from the seeds of the water melon. The milk of the camel is much esteemed, and the flesh, especially of the female, which is fattened for the purpose, is much used for food. There are two or three distinct breeds of *sheep*, but not materially differing from each other. Their wool is coarse, similar to hair, and apparently unfit for any manufacture. Their flesh is inferior to that of the Egyptian breed. The *goats* are more numerous than the sheep; their flesh is cheaper; and they grow to a larger size than those of Egypt. The *dogs* resemble those of Egypt. The common house *cat* is scarce, and is chiefly brought from the country. The beasts of prey are principally the lion, the leopard, the hyena, the wolf, the jackal, and the wild buffalo; but, excepting the hyena and jackal, they are not commonly seen within the cultivated parts of the empire. The latter are harmless, but their uncouth howlings are heard to a great distance. The former enter the villages at night in companies of six or eight, kill dogs or asses, drag off the dead carcases of camels or other animals, and are not much alarmed at the sight of a man, or the report of fire arms. The people of the country dig pits for them; and when one is entrapped, they stun him with clubs, or pierce him with spears. There are found also elephants in herds sometimes of several hundreds. They are smaller than those of Asia, and are hunted by the Arabs, who aim at them with spears, or make pits into which they fall. Their flesh is greatly esteemed as food, their fat as an unguent, and their hide as serviceable for many useful purposes. The wild buffaloes are hunted in like manner, and used as food. The hippopotamus is also hunted for his teeth, which are superior to ivory, and his hide, which makes excellent shields and whips. There are found also the camelopardalis, rhinoceros, crocodile, antelope, ostrich, civet cat, jerboa, and porcupine.

Wild beasts.

Birds.

Among the birds, the most remarkable are the *white headed vulture*, a bird of surprising strength, and said to be remarkably long-lived. They are very numerous in the inhabited districts; and carry off, in the day time, the carrion which the hyena has left during night. Near the extremity of each wing there is a strong sharp horny substance, resembling the spur of an old cock, which they use as a formidable instrument of attack. The *guinea fowl*, of great beauty, is found in abundance, and is carried as a profitable commodity to Cairo. There is no external distinction observable between the male and female of this bird; and their voice, when apparently elated, is very peculiar. *Green parroquets* fill the trees in the beginning of summer; and, being caught young, are tamed, and carried to Egypt, where they are taught a kind of speech, and sold at a high price. The other birds found in the country are, the quail, dotteral, pigeon, partridge, and owl. Fish of the same kinds as those of the Nile in Upper Egypt, are found in the river Ada, and are caught in wicker baskets. The natives have a method of drying them; but they are so offensive to the smell, as to be useless to any except themselves.

Fish

Reptiles and insects.

The *chameleon* abounds in Dar-fur, and is considered as an impure animal by the natives. Serpents, lizards, reptiles, and insects of various kinds are sufficiently common. The *scorpion* is of a small size, a brown hue, and not very malignant venom. Its sting is cured by the natives, by the immediate and renewed application of a bruised onion, till the pain subsides. The *white ant* is extremely destructive, eating through every thing within its reach. The *common bee* abounds, but no hives are in use, and the wild honey has a very unpleasant taste. Great quantities of *cochineal* are to be seen, but the natives apply it to no useful purpose. The *locust* of Arabia is very common, and is frequently roasted and eaten, particularly by the slaves. The mosquitoe is peculiarly troublesome in the rainy season.

Minerals and metals.

The rocks in Dar-fur consist chiefly of grey granite, and are used as mill-stones; but there is scarcely any stone suitable for building or convertible into lime. *Alabaster*, however, and various kinds of marble, are found within the limits of the empire. *Fossile salt* is not uncommon in a certain district; and there is a sufficient supply of *nitre*, of which, however, no use is made. *Sulphur* is brought by the Arabs from the south and west; and the hot springs, said to be found on the mountains called Gebel Marra, may be the effect of sulphureous vapours. The different metals are also said to exist towards the south and west. The *copper* is of the finest quality, resembling that of China, and appearing to contain a portion of zinc. *Iron* is found in abundance, but the natives have not the art of hardening it into steel. There is much *gold* in the countries on the east and west, but little is brought to Dar-fur; and there is little silver, lead, or tin, except what comes from Egypt.

Inhabitants.

Of the people of Dar-fur a great proportion are Arabs, many of whom lead a wandering life on the frontiers; and are in so unsettled and independent a state, as to be scarcely subservient to the purposes of the government, either in peace or war. Another portion consists of the people of Zeghawa, who once formed a separate nation, and who still speak a different dialect from the Furians. A third class comprehends the people of Dageou, who are also a distinct tribe, formerly the rulers of the country, but now subject to the sovereign of Fur. The natives of Kordofan, and of some other smaller kingdoms, are likewise dependant on the crown of Dar-fur; and a considerable portion of the inhabitants of the country, especially of one of the larger cities, viz. Cobbé, are properly foreigners, traders from Egypt, and from the countries on the Bahr-el-Abiad, or western branch of the Nile, viz. Dongola, Mahas, &c. as far as Sennaar. These are supposed to have first opened the communication between Dar-fur and Egypt; and are described as daring, restless, and turbulent, full of enterprise, and indefatigable in commerce. They usually intermarry with each other, or with the Arabs, and are easily distinguishable from the natives of the country. They have a good stature and figure, often an agreeable and expressive countenance, an olive complexion, short, black, and curly, but not woolly hair, and a form of visage altogether more resembling the European than the African. The amount of the whole population cannot be estimated with any degree of precision. There are not more than eight or ten towns of any considerable extent, and the most populous of these does not

Dar-fur. contain above 6000 inhabitants. There are numerous villages; but the largest consist only of a few hundred souls. Two thousand men are accounted a large army; and from all these considerations, Mr Browne calculates the whole population of the empire as not exceeding 200,000.

Character. The people of Dar-fur are sufficiently cheerful in their dispositions, and have little of that gravity of manner, which Mahommedanism requires. They are remarkably addicted to drunkenness; but are unprovided with any other fermented liquor than bûza or merisi. In this liquor, (though prohibited by the Sultan, under pain of death, on account of the quarrels and bloodshed which often attend their excesses,) they often indulge from sun-rise to sun-set, till each individual has swallowed nearly two gallons; but it is said to possess a diuretic and diaphoretic quality, which prevents any injurious consequences to their health from such intemperance. They are noted for thieving, lying, fraud, and all the concomitants of these vices; so that in making a bargain, the parent and the child will mutually glory in deceiving each other; and no property is safe in any place unless the owner be stronger than the thief. They are libidinous to an extreme, are addicted even to incestuous intercourse; and practise their licentious indulgences almost in open day, without any restraint or decency. They are not much attentive to personal cleanliness; and rarely either comb their hair, or thoroughly wash their bodies. They are unacquainted with the use of soap, and are contented to polish the skin with unguents. They have, however, a method of cleaning their bodies, by means of a farinaceous paste, which is applied with butter to the skin, and rubbed continually till it become dry; an operation which is accounted one of the highest luxuries. They differ in their figure from the negroes of the coast of Guinea; their complexion is perfectly black, and their hair short and woolly, but sometimes eight or ten inches in length, which is esteemed a beauty. As soldiers, they are not famed for skill or courage; and in their campaigns, reliance is placed chiefly upon the Arabs, who accompany them, but who are rather tributaries than subjects to the Sultan.

Houses. The houses of the Furians are remarkably slight and simple in their structure. The walls are built of clay, which the more wealthy cover with a kind of plaster, and paint them white, red, or black. The roof consists of light beams laid horizontally from one side to the other, on which is spread a stratum of light wood or coarse mats; over these is laid a quantity of dried horses or camels' dung; and the whole is finished with a strong smooth coating of clay. Their apartments are of three kinds; the *donga*, generally about 20 feet by 12, having a door of a single plank secured by a padlock, and thus forming the repository of all their property; the *kournack*, usually larger than the last mentioned, without a door, slightly thatched with the straw of the maize, and appropriated, as the coolest place, to sleeping and the reception of company; the *sukteia*, of a round form, from 15 to 20 feet in diameter, and constructed like the preceding, and in this the women are lodged and the food prepared. A *rukkuba* is frequently added, which is nothing more than a place sheltered from the sun, where a company may sit and converse in the open air. A house, containing two of each of these three kinds of apartments, is considered as large and commodious, and fit for the use of the wealthier merchants; but the village houses have generally nothing more than one apartment, of the form of the *sukteia*. Every habitation is generally surrounded with a thick hedge of dried branches of the acacia and other thorny trees, in order to secure the cattle, and prevent the escape of the slaves; and the houses are separated from each other at such wide intervals, that often in an extent of two miles in a line, not more than 100 distinct inclosures are visible.

Food. The grain chiefly used by the Furians, is millet, which, when coarsely ground, is boiled in the form of polenta, and eaten with fresh or sour milk, or more frequently with a kind of sauce made of dried meat pounded in a mortar, and boiled with onions, &c. The grain is frequently eaten raw, and merely moistened with water, without either grinding or baking. It is also formed into thin cakes, called *kissery*, or sections; but, in whatever way it is used, the richer class generally cause it to undergo a slight fermentation before it be ground, which gives it a pleasanter taste, together with an inebriating and narcotic quality, and then form it into a kind of paste, which will keep a long time, and is prepared for use by the addition of a little water.

Manufactures. Some of the principal manufactures are strong coarse cotton cloths, called *tokeas*, which form the covering of the lower classes; and sacks for corn or water, made of leather, which they are very dextrous in depriving of the hair and tanning for the purpose. They also make a kind of earthen ware, which they have the art of glazing; and the Arabs weave wicker baskets of so close a texture, as to hold milk, water, buza, &c.

Coin. Nothing resembling current coin is to be found in the country; and all commerce is carried on by simple exchange. Sometimes, as a medium of exchange for articles of little value, they make use of small tin rings, beads, salt, &c.; and this last mentioned substance they procure by collecting and boiling the earth of those places, where horses, asses, camels, and other animals have been long stationary.

Women. The Furians take as many wives as they can support, but are not so watchful over the conduct of their women as the Egyptians, and most of the other Africans. They do not retire at the approach of strangers, but freely enter the houses even of the foreign traders, and make their purchases at their leisure. They perform most of the laborious offices, build the walls of the houses, prepare the soil for the seed, sow, reap the corn, grind and convert it into bread; and it is not uncommon to see a man on a journey mounted upon an ass, while his wife is on foot behind him, carrying, perhaps, a supply of provisions, or of culinary utensils; yet the husband is not despotic in the house, but the wife has her full weight in the domestic economy.

Miscellaneous customs, &c. The people of this country are fond of dancing, and men and women often take this amusement promiscuously. Each tribe has its appropriate dance, some of which are grave, others lascivious, and all of them consisting rather in violent efforts than in graceful attitudes. The diseases most commonly observed among the people of Dar-fur, are a kind of leprosy, which gives to the skin and hair a white colour; umbilical ruptures, hæmorrhoides, the guinea-worm, bilious complaints, and the small-pox. The old women are the regular physicians; but their remedies are chiefly charms and exorcisms, such as writing sentences of the Koran on a board, and washing them off with water, which is given to the patient to drink. Several vernacular dialects are spoken in the country, but the Arabic is generally understood; and the judicial proceedings are immediately translated from the one to the other by a public interpreter. Among the customs peculiar to this country

Darien. may be mentioned the two following:—At the accession of a new king, the carpets on which the several deceased sultans used to sit, are spread before him, and whatever of them he prefers, it is concluded, that his character will resemble that of its former possessor. There is observed an annual festival, called *geled-el-nahas*, or the leathering of the kettle-drum, already noticed, which continues eight or ten days in succession. During this time, every subject, unless he be an absolute mendicant, is expected to come forward with some offering to the monarch; who, on his part, keeps an open table, or rather kitchen, during the festival. There is, at the same period, a review of all the troops not on actual service, if review it can be called, where every man, who has or can procure a horse, mounts and shows himself at this national meeting. See Browne's *Travels in Africa, Egypt, and Syria.* (*q*)

DARIEN, is a province of the kingdom of Terra Firma, or Castile Del Oco. This kingdom is divided into three provinces, Panama, Darien, and Veregua, of which Darien is the most extensive. It is bounded on the north and south by the two seas, on the east by the gulf or river of Darien, and on the west by another part of the South Sea and the province of Veregua. Its limits are not accurately ascertained; according to the ex-jesuit Coleti, it is 100 leagues in length; but Alcedo and other well-informed authors say that it is only 68 leagues long. At the broadest part, it is about 50 leagues wide, north and south. The whole kingdom of Terra Firma, according to Ulloa, is 180 leagues from east to west; but if the windings of the coast are reckoned, it is 213 leagues. The breadth of the kingdom is the same as that of the Isthmus of Darien, which includes the whole province of Panama, and part of that of Darien.

Extent.

The province of Darien is mountainous and rugged; but there are in it several *Llanuras*, or plains, which are fertile, but deserted, uncultivated, and not very healthy. The only produce of these plains is a little cacao and tobacco, the quality of both of which is excellent. There are a great many rivers in Darien, some of which run into the North Sea, and some into the South. The principal of the former are the Darien and the Chape; of the latter the Peto and Caynuto. The Atrato, Darien, or Choco, takes its rise in the mountains of the province of Choco, from two lakes; its course is nearly strait from south to north for ninety-five leagues, when it enters the North Sea, collecting, as it runs, the waters of the Andageda, Quito, Litasa, Zipe, Torron, and Pequerto, and of the lake Luina, and other streams, so as to form a mouth upwards of five leagues broad, in the Gulf of Darien. This river is navigable for many leagues. Till within these few years the navigation of it was prohibited under pain of death, under the pretence that it would injure the provinces of the Nuevo Reyno, as they might be easily entered by it; but in reality to prevent the gold, which is very abundant near its source, from being carried away. According to Humboldt, the navigation of this river is now declared free, and in consequence of this, the fraudulent exportation of the gold of Choco has much increased, especially at those times when foreign vessels are permitted to bring negroes from Africa, and flour from Philadelphia. As the Darien takes its rise near the gold mines of Choco, its sands abound in gold. Near its entrance into the sea, there are a number of small islands. Its mouth lies in latitude 8° 2′ North. The Chape rises in the mountains near the valley of Pacora. In its course it makes many windings, which are called *randantes*. It is navigated by vessels without keels, called chatas, as far as Cruces. On its banks near its entrance into the North Sea, there are many forts, as its navigation is watched and guarded by the Spaniards with nearly as much jealousy and suspicion as that of the Darien. It abounds in alligators, and the musquitoes on its shores are particularly troublesome. There is also found in it an immense number of a very small fish, about the size of a pin, called *titics*, which are drawn out with a basket. The mouth of the Chape is in 9° 18′ North Latitude. Ulloa, in his passage up it, ascertained, that the greatest velocity of its stream was about a league an hour. Cruces, where it ceases to be navigable, is about five leagues from Panama.

Rivers.

Darien. Rivers.

A great difference is observed in the tides in the North and South Seas. Those tides which in the ports on the North Sea are reckoned irregular, are considered regular in the ports on the South Sea: when they cease to increase or decrease in the former, they both rise and fall in the latter, extending over the flats, and widening the channels. Ulloa, who notices this circumstance, declares himself unable to account for it; "all that can be said, is, that the isthmus separating the two seas, confines their waters, whereby each is subject to different laws."

Tides.

The mountains in the province of Darien belong to one of those three remarkable chains, which are noticed by Humboldt as proceeding from east to west, parallel to the equator. This chain extends by Popayan and Choco, on the west of the river Darien, towards the isthmus, where, on the banks of the Chape, it forms mountainous land about 1200 feet high.

Mountains.

The gold mines of Darien at one period were very abundant and profitable, affording metal of a much finer quality than those in the provinces of Vereguas and Panama; but it was found necessary to abandon most of them, in consequence of the revolt of the Indians, so that only a few remain on the frontiers, which yield a small quantity of gold. The gold mines at Choco, where the river Darien takes its rise, have already been noticed. The largest piece of gold ever found there weighed 25 pounds.

Gold mines.

The most fatal disorder which rages in Darien is the *vomito*: it rages frequently with great violence on both coasts of the Isthmus, but the causes are supposed by Humboldt to be very different. At Panama, the *vomito* is endemical. Here the tides are very strong, and throw up great quantities of marine plants; these being exposed to the heat of the sun, putrefy and infect the air; hence, at Panama, the shore is considered as the origin of infection. At Porto Bello, on the contrary, the putrid emanations proceed from the very great strength and luxuriancy of vegetation. Here the tides are scarcely perceptible. That this is the cause of the insalubrity of Porto Bello, is apparent from the following fact. Till within these few years, the forests which cover the interior of the isthmus, extended to the very gates of the town; since the environs have been cleared, the salubrity of the air has been greatly increased.

Diseases.

Both on the north and south coasts of Darien, there are two sorts of general winds; the one called *brisas*, (breezes,) which blow from the north-east; and the other called *vendebales*, which blow from the west and west-south-west. On the north coast, the former set in about the middle of November, but are not fixed and regular till the beginning or middle of December. On the south coast, the *brisas* are later. On both coasts, they continue to blow till the middle of May: they

Climate.

Darien.

then cease, and are succeeded by the *vendibales*, which, however, do not extend farther than 12 or $12\frac{1}{2}$ degrees of latitude, beyond which the *brisas* blow, with less steadiness and regularity, however. At the period when the brisas blow strongest, a very impetuous current sets into the Gulf of Darien; and on the contrary, while the *vendibales* blow, the current sets out of the Gulf with equal violence.

Darien was the first province in Terra Firma in which the Spaniards established themselves. It was conquered by Vasco Nunez de Balboa, and was the scene of many of the valorous enterprizes of Francisco Pizarro. The settlement of Darien, which is the residence of the governor, was the first that was made on the continent of America, having been founded in 1509; but owing to the badness of the climate, it has now dwindled away to a miserable hamlet, exposed to the constant invasions and attacks of the Indians.

Inhabitants.

The natives of Darien are not numerous: in 1747, they were supposed to amount to 5000 families. They are brave, hardy, patient of fatigue and pain, but cruel, stupid, and faithless. The Spaniards have made many attempts to reduce them to subjection, but in vain; nor have they succeeded better in their attempts to convert them to Christianity. They soon relapse into their idolatrous habits, and retire into their native mountains. They are very skilful in the use of the bow and arrow. The former are made of a strong and flexible kind of wood, called *choata*. Their arrows consist of a species of light cane; the point being formed of fish bones, or of the same kind of wood as the bows. Their principal and most favourite food is the flesh of monkeys, of which animals there are here a wonderful variety. They ferment maize and plantains, from which they make a kind of drink, called *mazato;* with this they are fond of intoxicating themselves. They are nearly naked, but are fond of ornaments, especially golden rings pendant from their nose. The women adorn their legs and arms with strings of coral, beads of glass, and of gold. They pay great deference and respect to their priests, who render their countenances singularly horrible and deformed, by painting their faces of different colours, and making incisions, into which they insert bitumen. They are almost at constant war with the Chocoes. Their enmity to each other is said to have originated in the circumstance of the Indians of Darien having put to death a Christian priest, who was held in great reverence by the Chocoes, about the end of the last century. Since that time, every Indian of Choco carries a skull of an Indian of Darien, whom he has killed in war, out of which he regularly drinks. In consequence of this unintermitted hostility, and of the ravages of the smallpox, the numbers of the Indians of Darien are much diminished. They bear towards the Spaniards, perhaps, a more deadly enmity than any other of the Indian race in South America. In 1719, they rose against them in a body, and committed dreadful cruelties. The war continued till 1740, when a treaty was agreed upon, by the terms of which the Indians were to admit missionaries among them: but their efforts and zeal were of no avail, and the Spaniards were so exasperated, and at the same time so apprehensive of them, that it was proposed to free the Indians of Choco from their tribute, on the condition that they would join in exterminating the Indians of Darien: this plan, however, was abandoned. In 1786, another attempt was made to subjugate them. The viceroy of Santa Fé dispatched a large force against them, which succeeded in forming different establishments and settlements, but these were soon abandoned, in consequence of the badness of the climate, and the ferocity of the natives.

Darien scheme.

The advantageous situation of this province communicating with the two seas, its natural fertility, but above all, the reputation of its gold mines, have induced foreigners, at different periods, to attempt establishing themselves in it. Of these attempts, the most remarkable is that which was made by Patterson, a Scotchman, towards the close of the 17th century. It is said that he was originally a Buccaneer; who afterwards became a clergyman, and under pretence of converting the Indians, visited the New World. He was undoubtedly a man of an original mind, and of a bold and enterprising disposition. He was the first projector of the Bank of England, and being defrauded of his just recompence by those who adopted his plans, he resolved to confine his future schemes to the benefit of his native country. On his original and ostensible design of establishing an East India trade in Scotland, he engrafted the secret and magnificent plan of forming an emporium on each side of the Isthmus of Darien, for the trade of the opposite continents. According to his idea, the manufactures of Europe were to be sent to the Gulf of Darien, and thence conveyed by land across the ridge of mountains that intersects the Isthmus, where they were to be exchanged for the produce of South America and of Asia; and thus, to use his own emphatic language, he would wrest the keys of the world from Spain. In order to attract encouragement and support, he proposed to render his settlement a free port, and to banish all distinction of party, religion, or nation. But Scotland was at this time very poor; and the difficulties arising from her poverty were increased by the opposition which the plan met with in England. An alarm, first excited by the East India Company, and the West India merchants, soon spread over the whole nation. Even the parliament addressed the king in a violent and absurd address, remarkable for narrow and illiberal views; and the king appearing to fall in with the clamour, the Indian Company, whom Patterson had succeeded in establishing, withdrew their subscription, and relinquished their designs. But Patterson himself was not to be easily intimidated; and the Scotch nation, indignant at the opposition which the plan had met with in England, avowedly because it would be beneficial to Scotland, immediately subscribed L.400,000. Besides this sum, L.300,000 was subscribed at Hamburgh, which, however, was withdrawn, in consequence of the threatening memorial presented by the English resident to the senate of that city. The Scotch, nevertheless, persisted in their scheme: five large vessels, laden with merchandise, military stores, and provisions, with a colony of 1200 persons, sailed for the Isthmus of Darien. King William, however, still opposed it: his policy and wish were to oppose the aggrandisement of the House of Bourbon; and to accomplish this, he wished to keep well with Spain. In the mean time, the fleet arrived in the Gulf of Darien; and the settlement was very judiciously formed at Acta, a place at an equal distance between Porto Bello and Carthagena. Here is a secure and capacious harbour, formed by a peninsula, which the colonists fortified, and named Fort St Andrew. To the settlement they gave the name of New Caledonia. Of the 1200 persons who had embarked, 300 were gentlemen, unaccustomed to labour, fatigue, or homely fare, and totally unacquainted with any of those arts which are indispensibly necessary in a *new* colony. These consequently were of little use; and even the peasants, habituated to a cold climate, were unequal to the fatigue of clearing the ground under a burning tropical sun. In addition to these untoward circumstances, their provisions were either improper for the climate, or soon exhausted. The cargoes of merchandize which they sent to the West India islands, were not properly adapted for that market. The infant colony was attacked by the Spaniards, and proclamations were issued at Jamaica, Barbadoes, and in the American plantations, prohibiting all succour or access to the Scotch at Darien, on the pretence that their settlement there was an infringement of the alliance between England and Spain. For eight months the colony bore up against these accumulated misfortunes and persecutions; but at the end of this period, those who survived were compelled, by disease and famine, to abandon their settlement, and return to Europe. Before this circumstance was known, two other expeditions sailed from Scotland; and the information of the abandonment of the first colony only served to rouse the Scotch nation to more determined perseverance in the plan. When the second expedition arrived, they found the huts burnt, and the forts demolished; famine and disease assailed them; they were attacked by the Spaniards from Panama, these they repulsed; but a larger force coming from Carthagena, obliged them to capitulate, on condition that they should embark with their effects for Europe; few, however, of these, or of the other two colonies, survived to return to Scotland. The Scotch nation, at this utter and irremediable failure of a scheme, from which they anticipated great wealth, were highly indignant: they endeavoured to extort from William an acknowledgment of the national right to Darien; and failing in this, they presented an address to him, to assemble the Scotch Parliament: when it did assemble, a resolution to assert the national right to their colony, was only prevented by adjournment, and ultimately by proroguing the Parliament: It was, however, soon necessary to reassemble and mollify it, in order to get the supplies for the army; and when it did meet again, some very popular and spirited resolutions were adopted on this subject. The Scotch nation were never afterwards thoroughly reconciled to King William, and even for many years subsequent to his death, the remembrance of the loss of Darien was preserved with resentment and regret. In this scheme, £200,000 had been sunk; and at least as much had been expended in the purchase of provisions for the colony: Many families were reduced to ruin, and few had escaped without the loss of a relative or friend. It is melancholy to reflect on the failure of this grand and noble design, especially when we consider that if the colony had been maintained only a few years longer, the succession war would have secured the Scotch in the firm possession of the country. Patterson, on his passage home, after the ruin of the first colony, was seized with lunacy, from which, however, he recovered. He lived many years afterwards, pitied, respected, and neglected. The famous Mr Law, who was a youth at the time of the expedition to Darien, acknowledged that he was induced to project his Mississippi scheme, from the rapidity with which he perceived the spirit of speculation communicate itself on this occasion.

It is rather a remarkable circumstance, that Patterson should have happened to select for the seat of his colony, the only point where it would be perfectly practicable to open a communication between the two seas. Ever since Vasco Nunez de Balboa crossed the isthmus in 1513, this scheme has been fondly cherished, and several places have been pointed out, where it was supposed it could be carried into execution.

Places for opening a communication between the two seas.

1. The river Chape has been pointed out: this river, as has been already mentioned, falls into the Atlantic, about eighteen leagues to the westward of Porto Bello, and is navigable as far as Cruces, within five leagues of Panama: but to this mode of communication there are two strong objections; in the first place, from the accounts of Ulloa and Humboldt, the navigation of the Chape is extremely difficult, dangerous, and slow; it is obstructed by *races*, or swift currents over the shallows, where vessels, even though built on purpose, cannot proceed for want of a sufficient quantity of water: in the second place, the distance between Panama and Porto Bello is not known, and the intervening country is remarkably mountainous. So imperfectly is the relative situation of these two places ascertained, that the French geographers contend that Panama lies on the east side of Porto Bello, and the Spaniards place it on the west side. Ulloa, from his bearings in sailing up the Chape, concluded that Panama was situated 31′ to the west of Porto Bello, while, according to Fidalgo, who formed his map of the isthmus from astronomical and trigonometrical operations, Panama lies 7′ to the east of Porto Bello. Humboldt, who took great pains to ascertain the practicability of this mode of communication, is of opinion that it could not be effected, except on a small scale, and by means of locks and tunnels. A modification of this plan has been proposed: about five leagues from the mouth of the Chape, it receives the river Trinidad, which is navigable to within thirty miles of Panama; and it is said this space is level, and might easily be cut through: but too little is actually known respecting this tract, to decide on the practicability of the plan.

2. To the north of the Chape is the grand lake of Nicaraguay, which stretches nearly from sea to sea, and falls into the Atlantic Ocean by a navigable river. In the time of Charles III. a proposal was made to effect a communication by means of this lake: but the coast of Nicaraguay is inaccessible to shipping during the months of August, September, and October, on account of thunder storms and dreadful rains; and during the months of January and February, on account of the violent winds from the north-east.

3. The Mandinga takes its rise in the mountains of Chape, and runs east till it enters the bay, to which it gives name: this bay commences about ten leagues to the eastward of Porto Bello, and penetrates into the isthmus to within about five leagues of the Pacific Ocean: from the mountain where it takes its rise, the river Chape also flows, which falls into the gulf of Panama. Little is known respecting the navigation of these rivers, or the nature of the intervening country; but the Buccaneers penetrated from sea to sea, in this direction, in 1679, and the navigation of the Mandinga is prohibited by the Spanish government, under pain of death.

4. But the most commodious spot is undoubtedly that pointed out by Humboldt, in the bay of Cupica: between it and the river Naipi, where it becomes navigable, there are only five or six leagues of a flat, level, country, and the river Naipi terminates in the river of Darien: in this direction only, is the chain of the Andes interrupted. Near the source of the Darien, in the province of Choco, a communication has actually been opened between the two seas, ever since the year 1788. In this province there is a small ravine, lying between

one of the branches of the river St John and the Quito, which falls into the Darien: in this ravine, the Rector of Arvita has caused his flock to cut a small canal, which is navigable in the rainy seasons, and by means of which canoes, laden with cacao, have passed from sea to sea. See Humboldt's *Political Essay on New Spain*; Ulloa's *Voyage to South America*; Alçedo's *Geographical and Historical Dictionary of America and the West Indies*. (w. s.)

DARIUS. See PERSIA.

DARLINGTON, a market and borough town of England, in the county of Durham, is situated on the side of a hill, gently sloping to the east, at the foot of which runs the river Skerne, which is crossed by a bridge of three arches, and which runs into the Tees. The town consist of several well built streets, diverging from a square, in which the markets are held; and it contains several good modern built houses and excellent inns. The principal public building in Darlington is the church, which stands at the south-west angle of the market-place, and which was erected in 1160, by Bishop Hugh Pudsey. It is a spacious edifice in the form of a cross. The tower and spire rise from its centre to the height of 180 feet; and the stone of which it is built is said to have come from Cockfield-fell, a distance of twelve miles. The tower rises from uniform arches supported by clustered pillars, and the arches of the naves and aisles are irregular. The west door is highly finished. In 1567, a grammar school was endowed by Queen Elizabeth out of the funds of Marshall's chantry. The school, and the building, which was once the bishop's palace, are situated near the banks of the river. The last of these buildings is now farmed from the bishop's housekeeper as a work-house for the poor.

There are several flourishing manufactures in this town. Tammies, moreens, and other woollen stuffs are fabricated in great quantities, and there is a thriving manufactory of linen goods, such as diapers, huckabacks, and checks. The cotton manufactory, which was lately introduced, is in a flourishing state. There is also in this town a mill for spinning wool. In the neighbourhood of Darlington, a mill was erected by John Kendrew, a native of the place, for grinding and polishing lenses or glasses for optical purposes. The same artist erected another mill for spinning hemp and flax. A respectable agricultural society, which distributes premiums, holds its meetings in this town, and has already contributed to the improvement of agriculture. A sulphureous spring, which has been found of use in scorbutic and other complaints, was discovered in 1803, and is now much frequented.

The following is the abstract of the population return for 1811 for the township of Darlington:

Inhabited houses	818
Families that occupy them	1205
Families employed in agriculture	143
Families employed in trade and manufacture	850
Families not included in these classes	212
Males	2351
Females	2708
Total population	5059

See Hutchinson's *History of Durham*, and Brayley and Britton's *Beauties of England aud Wales*, vol. v. p. 83, &c. (j)

DARMSTADT, a town of Germany, and capital of the Grand Duchy of Hesse Darmstadt, is beautifully situated in a fertile territory on a small river of the same name, and about three leagues from the eastern bank of the Rhine. The principal objects of curiosity in this town are the palace, which is a stately building; the hall of the emperors, the public library, the library of the grand duke, the buildings of the tribunals, the academy of music, the schools of the town and the garrison, the school of industry, the cabinet of natural history, which contains several remarkable fossil bones of a huge size, which served as pillars to a house at Kostheim; the opera house; the large building for military evolutions, which admits about 1500 men for the manual exercise, and has 16 stoves; the military school; the college; the gardens of the palace; the gardens of the Grand Duke at Bersungen and Kranichstein; the chateau and the mineral waters of Auerbach; and the large manufactory for harness and wheel-work. On the summit of a mountain, near the district called Bergstrasse, and not far from Heppenheim, is a column of granite about 33 feet long, known by the name of Riesensaule, or the Pillar of the Giants. An altar 14 feet in circumference stands very near it. This town was lately celebrated for a dye-work in the house of the orphans; but we are unable to ascertain whether or not it is still in existence. Darmstadt is the ordinary residence of the Grand Duke, who was a member of the Confederation of the Rhine. The fate of this town will depend on arrangements which will soon be made, in consequence of the recent dissolution of the Rhenish Confederation. Population about 12,000, or 13,000, according to Catteau. See Reichard's *Itineraire de Poche de L'Allemagne et de la Suisse*, Paris, 1809; Catteau's *Voyage en Allemand et en Suede*, vol. i. p. 229. See also CONFEDERATION of the Rhine. (π)

DART. See DEVONSHIRE.

DARTFORD, a market town of England, in the county of Kent, which derives its name from the ford of the river Darent, on which it is situated, in a narrow valley between two hills. It was called *Derent-ford* by the Saxons, and is spelt Tarenteford in Domesday-book. The town consists of a principal street, through which the high road passes, and of two smaller ones going off at right angles. The chief public buildings are the church, the place-house, and the bridge. The church, which stands in the north east part of the town, near the river, is a large building, consisting of a nave, chancel, and aisles, with a tower which is embattled at the north-west side. In the chancel, on the north side, is a mural monument of Sir John Spelman, who had the merit of first introducing the paper manufacture into Britain. He and his lady are exhibited as kneeling at a desk. In the church there are several slabs inlaid with brass, some of which are curious and deserving of attention. The place-house was formerly a nunnery, established by Edward III. in 1355. Henry VIII. fitted up the buildings as a palace. Its remains are of brick, and consist of a large embattled gateway, with some buildings in the south, which are now occupied as a farm house. From the many drains and foundations of wells that have been discovered, the building must have occupied a great extent of ground. The stone wall which enclosed the garden is still entire. The bridge was formerly very narrow and dangerous, but was widened about 30 years ago at the expence of the county. The old market house and shambles were taken down about the same time, and new buildings erected instead of them in a more convenient situation. Below the town there is a good wharf. The principal manufactures of Dartford are gunpowder and paper. On the site of a wheat and malt mill, about a mile

Dartmoor, Dartmouth.

above the bridge, Sir John Spelman erected a mill for writing paper, and the same place is now occupied by the gunpowder mills. The present paper mill, which is a short distance below it, was erected on the place where Geoffrey Box of Liege built, in 1590, what is supposed to have been the first mill in England for slitting iron bars into rods.

The following is an abstract of the population return for 1811, for the parish of Dartford:

Inhabited houses,	526
Families that occupy them,	732
Ditto employed in agriculture,	251
Ditto in trades and manufactures,	308
Ditto not included in these classes,	173
Males,	1599
Females,	1578
Total population in 1811,	3177

See Hasted's *History of Kent*; and Brayley's *Beauties of England and Wales*, vol. vii. p. 557—565. (*j*)

DARTMOOR. See Devonshire.

DARTMOUTH, a borough and sea-port town of England, in Devonshire, situated near the place where the river Dart discharges itself into the British Channel. Mr Gilpin describes the bay formed by the mouth of the river, as one of the most beautiful scenes on the coast. "Both the entrance of the Dart into it, and its exit to the sea, appear from many stations closed up by the folding of the banks; so that the bay has frequently the form of a lake, only furnished with shipping instead of boats. Its banks are its great beauty. They consist of lofty wooded hills, shelving down in all directions." The town itself has also a fine appearance when seen from the bay. The houses, embosomed in trees, appear on the slope of a craggy hill, stretching almost a mile along the water's edge. The dock-yards and quay project into the river; and the rocks on each side consist of a glossy slate of a purple hue, having plants and shrubs on their summits.

Dartmouth formerly consisted of three villages, Dartmouth, Clifton, and Hardness, which are now united by buildings. The streets are very irregular, some of them being so much higher than others, "that it is almost possible to shake hands from without with a person at the window of an attic story." The streets are disagreeably narrow, and the lower tier of houses often communicate, by means of steps, with those above. The principal street, which is spacious, fronts the quay, and is chiefly inhabited by merchants. There are three churches in this town, besides a dissenting meeting-house. St Clement's stands on a hill about a quarter of a mile from the town, and has a tower 70 feet high. There are also three charity schools for the education of the poor. At the south end of the town are the remains of an ancient castle, rising immediately above the water. It appears to have been circular, but not strong.

The harbour, the entrance of which is defended by a castle, and two platforms of cannon, is very secure, and is capable of holding 500 sail. The castle was probably erected in the time of Henry VII. It is not large, and has but a few cannon upon its walls, but is remarkable for its picturesque situation.

The trade of this town arises chiefly from the Newfoundland fishery, which furnishes employment to about 3000 men, and is carried on to a great extent. About 350 vessels are employed in this trade, both in catching the fish, and in carrying them, when cured, to foreign markets. They are taken principally to the ports in the Mediterranean, and the vessels bring home, wine, oil, fruit, and salt. A number of ships are also employed in the pilchard fishery. Ship-building is carried on to a considerable extent. To the north of Dartmouth harbour lies Torbay, the famous rendezvous of the British fleet during inclement weather. Distance of Dartmouth from London $203\frac{1}{2}$ miles.

Darwin.

The following is an abstract of the population return for 1811, for the parishes of St Petrox, St Saviour, and Townshall, which form the borough of Clifton Dartmouth, Hardness:

Inhabited houses	364
Families that occupy them	842
Do. employed in agriculture	93
Do. in trade and manufacture	468
Do. not included in these classes	281
Males	1464
Females	2131
Total population, in 1811	3595

See Polywhele's *History of Devonshire*; Dr Maton's *Tour through the Southern Counties*; and Britton and Brayley's *Beauties of England and Wales*, vol. iv. p. 127—131. (*j*)

DARWIN, Erasmus, an eminent philosopher and physician, was the son of Robert Darwin, Esq. a barrister, and was born on the 12th of December, 1731, at Elveston, or Elston, in Nottinghamshire, where the family had a seat. He went through the usual routine of grammar-school education, at Chesterfield, under the tuition of the Rev. Mr Burrows. While under this gentleman's care, he made a very great proficiency in the attainment of classical learning; and even at that early age, discovered some of that poetical genius, and evinced that thinking and philosophical mind, which gave him so much celebrity in future years. The mathematics seemed to have no allurements for him; and his knowledge of that science was never extensive. To mechanical knowledge he was partial, and, during the course of his life, invented several ingenious contrivances. In the year 1753-4, he removed to Edinburgh, where he studied medicine; and from that to St John's College, Cambridge, where he took his degree of M. B. in 1755; and in his Thesis on that occasion, maintained that the movements of the heart and arteries are immediately produced by the stimulus of the blood. While at Cambridge, he composed a poem on the death of Frederick, Prince of Wales: it was printed among the Cambridge collection of verses on that occasion; but the merits of this, as well as some other pieces of poetry, which he occasionally produced about this time, do not rise above mediocrity, though they are ingenious and respectable.

Having completed his studies, he went to Nottingham, with the intention of settling there as a physician; but not meeting with success, he removed to Lichfield in 1756. At this time he was twenty-four years of age, rather above the middle size, his form athletic, and inclined to corpulency, and his limbs too heavy for exact proportion. The traces of a severe small-pox; features and a countenance which, when they were not animated by pleasure, were rather saturnine than sprightly; a stoop in the shoulders, and the then professional appendage, a full-bottomed wig, gave him, at that early period of life, an appearance of nearly twice the years he bore. Florid health, and earnest good humour, a cheering smile on entering a room, and on first accosting his friends, rendered in his youth that exterior agreeable, to which beauty and symmetry had not been propitious.

Darwin.

Soon after the arrival of Dr Darwin at Lichfield, his skill and discernment as a physician were put to the test. Being sent for to a young gentleman of family and consequence in the neighbourhood, who lay sick of a dangerous fever, and whose case had been pronounced hopeless by a celebrated physician, that had for many years possessed the business and confidence of the Lichfield neighbourhood; he, by a reverse and novel course of treatment, gave his dying patient back to a fond and despairing mother, with renewed existence and renovated health. This was the foundation of his prosperity; and this successful attempt gave him so high a degree of reputation at Lichfield and the neighbouring towns and villages, that his competitor finding himself neglected, and his reputation eclipsed by his youthful and ingenious rival, gave up the contest, and left the place. From that time his practice became very extensive; and his future efforts were attended by success equal to his first fortunate exertion.

In the year 1757, he married Miss Howard of the Close of Lichfield; a young lady, who, though only eighteen, possessed a mind of a very superior cast: a strong understanding; a taste for the works of imagination; ingenuous sweetness; delicacy, animated by sprightliness, and sustained by fortitude, were the qualifications which rendered her a proper and fascinating companion to a man of talents so illustrious. To her he could commit the important task of rendering his children's minds fit to receive the seeds of knowledge and of science, with confidence. But upon her youth, and a too delicate constitution, her having children in quick succession during the first five years after her marriage, had probably a baneful effect. Dr Darwin exerted all his skill and attention for the preservation of her valuable life: for thirteen years he was successful; and during that time she had five children, two of whom died in their infancy. Three, Erasmus, Charles, and Robert, were left to mourn her loss, and were distinguished instances of the importance of right principles being early instilled into the youthful mind. The first was an eminent attorney at Derby. To a most engaging disposition he united considerable talents; but his modest, diffident, and retired habits, had a tendency to increase his naturally indolent, procrastinating, and perhaps melancholy disposition, to such a degree, that the fatigue of attending his business wrought so powerfully upon his mind, that he voluntarily put a period to his career in the flower of his age.

Charles was born at Lichfield, in the year 1758. After receiving a preparatory education, he was sent to Christ-church College, Oxford, where he remained some time. From that place he removed to Edinburgh, where he studied medicine, and obtained the first prize medal offered by the Esculapian Society for the best essay. The subject was, the best means of distinguishing pus from mucus. In this paper, he states, "as the result of numerous experiments, when one wishes to examine the matter expectorated by his patient, let him dissolve a portion of it in vitriolic acid, and another portion of it in caustic alkaline lixivium, and then add pure water to both solutions. If there is a precipitation in each solution, it is clear the expectorated matter is pus; if there is no precipitation, the matter is simply mucus." He died at Edinburgh on the 15th May 1778. He left behind him an unfinished account of the retrograde motions of the absorbent vessels of animal bodies in some diseases, in Latin; a translation of which, together with the Dissertation for which he obtained the medal, were published by his father after his death. Robert settled as a physician at Shrewsbury, where he still remains, eminent as a professional man, and respected as a gentleman.

Dr Darwin's house during his residence in Lichfield, was the resort of a knot of philosophic friends, who frequently met in social converse. Among those may be enumerated Mr Watt, Mr Boulton, Mr Michel the astronomer, Mr Edgeworth, Mr Day, Sir Brooke Boothby, and Miss Seward. It is singular, that though Dr Johnson frequently visited his daughter-in-law, Miss Lucy Porter, at his native place, Lichfield, he and Dr Darwin had but one or two interviews; and that a mutual and strong dislike subsisted between them. Perhaps Dr Darwin's scepticism, in what Dr Johnson thought orthodox religion, supplies an easy solution of the cause of this enstrangement.

In the year 1781, Dr Darwin married a second wife, Mrs Pole, the widow of Colonel Pole, of Radburn, Derbyshire. This lady he had first seen in 1778, when she had brought her children, who were indisposed, to be under his care. While Mrs Pole remained with her children at the Doctor's house, her external accomplishments and internal qualifications inspired her philosophic host's admiration, and secured his esteem. In 1780, Colonel Pole died; and an opportunity was thus afforded the doctor of disclosing an affection, which he had long entertained, but which he was obliged to confine within his own breast. His addresses were accepted; and very soon after he left Lichfield and removed to Derby, where he resided about twenty years. His reputation, and the unlimited confidence of the public, followed him thither; and he once more became a happy husband, with a second family of children springing up fast around him. In the year 1801, he removed from Derby to the Priory, an estate which his son Erasmus, whose unfortunate catastrophe we have already noticed, had bought, and left to his father, who took a great pleasure in improving it. But, alas! his residence there was destined to be of no long continuance. He was subject to inflammation in his lungs, and had a serious attack in the spring of the year in which he left Derby. During these sudden and alarming disorders, he always applied the lancet, instantly and freely; and frequently rose in the middle of the night and bled himself. On the 10th of April 1802, he had a serious attack of this disorder, and at the same time a shivering fit. His surgeon took 25oz. of blood from him at different times on that day; and he so far recovered as to appear quite well, and walked and talked with his friends as usual. On Saturday the 18th of April, he rose at six in the morning, his common practice; and wrote several letters. But he had written no more than one page of a very sprightly one to Mr Edgeworth, describing, in a serene and happy manner, the Priory, and the alterations he intended making there, when he was seized with a shivering fit. He immediately rang the bell, ordered a quantity of butter-milk (which it was his custom to drink every morning) and desired Mrs Darwin to be sent to him. She immediately came accompanied by one of her daughters—they saw him shivering and pale; and though for a little he seemed to recover, he soon fainted, and expired between eight and nine o'clock, in the 71st year of his age. His body was opened, but no traces of a peculiar disorder was found; and the state of the viscera, indicated a much more protracted existence. He left a widow and six children, well provided for, all of whom are now living.

In his person, Dr Darwin was gross and corpulent, and unwieldy in his appearance, owing to a slight lameness, caused by an incurable weakness, proceeding from an accident which befel him at Lichfield, of breaking the patella of his knee. He stammered exceedingly, and his tongue, seemingly too large for his mouth, made it difficult for any but those who were accustomed to his society to understand him; and he could not bear to have his words anticipated. But whatever he said, whether gravely or in jest, was always worth waiting for; and the intelligence and benevolence with which his features were lighted up in conversation, did away every unpleasant sensation which might have been excited by any apparent deformity. His great benevolence of disposition was peculiarly conspicuous in his care of brute animals, and in the prevention of the exercise of cruelty towards them, and even to insects. His general manners were gentle, his temper cheerful, though sometimes hasty. He expressed his anger with vehemence, especially at any example of inhumanity or injustice. He became, in early life, sore upon opposition, whether in conduct or argument, and always revenged it by sarcasm of very keen edge. Nor was he less impatient of the sallies of egotism and vanity, and he seldom failed to present their caricature in jocose but wounding irony. No man exacted a less tribute of applause in conversation, though he was perhaps on some occasions too little accommodating to characters and circumstances. He possessed an ardent mind, was fond of admiration, and open to flattery. He was a warm friend to many. Modest merit found in him a fostering protection; truth and liberty, a strenuous and able advocate. Vice, and war, and oppression, a steady and indignant opposer.

The doctor carried his scepticism of human truth so far, that he often disregarded the accounts his patients gave of themselves, and rather chose to collect his information by indirect inquiry, and by cross examining them, than from their voluntary testimony. He avowed a conviction of the pernicious effects of all vinous fluids on the human system, and totally abstained from malt liquor, wine, and spirits of all sorts; and by his precepts upon this subject, and his correspondent example, he so diminished their use, that intemperance was scarcely known in the circle in which he moved during his life, nor since his death has it again prevailed. Acid fruits with sugar, all sorts of creams, with butter, were his luxuries, of which he partook in great quantities, and always ate plentifully of animal food. He was not attached to any peculiar profession of faith, or to the dogmas of any particular church. But however sceptical he might be in his religious belief, he was a warm friend to liberty of conscience, an indignant enemy to religious persecution, and perhaps on this account be called a deist or an atheist; but there are many passages in his works, where very fine religious sentiments are expressed. He, however, exhibited in his conduct, what is more beneficial to the world at large, than the tenacious adherence to any speculative opinions,—firm integrity, and a benevolent heart. Professional generosity distinguished his medical practice. Diligently did he attend to the health of the poor at Lichfield and Derby, supplied their necessities by food, and every kind of charitable assistance. In each of these towns, *his* was the cheerful board of almost open-house hospitality, without extravagance or parade, ever deeming the first unjust, and the latter unmanly. Generosity, wit, and science, were his household gods.

To the many rich endowments which nature bestowed upon Dr Darwin, may be added strong passions, and a lively and highly poetic imagination. He did not come forward very early as an acknowledged poet. The effusions of his early muse, were occasionally sent to one or another of the monthly publications, but without his name, conceiving, from the examples of Akenside and Armstrong, that the reputation he might acquire by his poetry, would operate as a bar to his advancement in the practice of medicine. His *Botanic Garden*, the first of his poems to which he put his name, was not published until the year 1791, when his medical fame was so well established, as to make it safe for him to indulge his taste in any way he should chuse. This poem consists of two parts. The first contains the economy of vegetation; the second the loves of the plants. Each is enriched by a number of philosophical notes, stating a great variety of theories and experiments in botany, chemistry, electricity, mechanics, and in the various species of air. They also contain explanations of every personified plant, its generic history, its local situation, and the nature of the soil and climate in which it is indigenous, its botanic and its common name. The general strain of this work is flowing and majestic. By an inversion of all custom, Dr Darwin published the second volume of this poem first, giving as a reason in an advertisement, that the appearance of the first part had been deferred till another year, for the purpose of repeating some experiments in vegetation. But the real cause was the consciousness he entertained, that the second part of his work would be more on a level than the first to the comprehension, more congenial to the taste of the superficial reader, from its being much less abstract and metaphysical, while it possessed more than sufficient poetic matter to entertain and charm the enlightened and judicious few. The novelty of the design, and the brilliancy of the diction, full of figurative expressions, in which every thing was personified, rendered the poem for some years extremely popular. But the fame which it acquired has in a great degree subsided. Some able critics are unwilling to concede to Dr Darwin the merit of originality in the manner and style of his versification, and maintain, that he closely imitated productions that appeared many years before the *Botanic Garden*. The sources from which he is accused of having drawn copiously, are *Universal Beauty*, a philosophic poem by Henry Brooke, 1735, in 24 vols. folio, and a Latin poem by De la Croix, entitled, *Connubia Florum*. The plan of the *Botanic Garden* is certainly like that of the latter, and there are many passages in it very similar in their cast and expression to the former. It is possible that Dr Darwin might have seen these works, and that his plan might have been formed in part from them; but this does not derogate from his merit in producing a poem, in which no writer has so successfully attempted the combination of philosophy with poetry.

Our author's next work was his *Zoonomia, or the Laws of Organic Life*, 4to. The first volume was published in 1794, and the second in 1796. The purpose of this work, the gathered wisdom of three-and-twenty years, was to reform, or entirely new model, the whole system of medicine; professing no less than to account for the manner in which man, animals, and vegetables are formed. It was his opinion that they all took their origin from living filaments, susceptible of irritation, which is the agent that sets them in motion. Notwithstanding its numerous defects, the *Zoonomia* is a great work, and the production of a surprising genius. The vast variety of curious experiments which it contains, and the uncommon powers of ingenious combinations, which it every where displays, render it an exhaustless repository of interesting facts, important to the health and comfort of mankind. It has, however, ceased to be popular: its doctrines are not always infallible; but some of its speculations have been since verified by the great discoveries made in chemistry.*

About the year 1795, Dr Darwin published a small Tract, in 4to, on female education. It contains some good rules for promoting the health of growing children; but, on the whole, it is a meagre work, of little general interest, and it consequently attracted but little notice.

Early in 1800, Dr Darwin published another large 4to volume, entitled, *Phytologia, or the Philosophy of Agriculture and Gardening*. His conviction that vegetables are remote links in the chain of sentient existence, often hinted at in the notes to the *Botanic Garden*, is here avowed in a regular system. The *Phytologia* insists, that plants have vital organization, sensation, and even volition; and a number of instances are adduced to support the theory. This work obtained but little attention from the public, and was suffered to pass almost unnoticed.

The last production of Dr Darwin, is the *Temple of Nature, or the Origin of Society*, 4to, with notes. This work, "the setting emanation of this brilliant day-star," the Doctor had prepared for the press, a few months before his death, and was published in 1803. It treats of the production of life; the re-production of life; the progress of the mind; and of good and evil. It seems designed to illustrate the theory laid down in the first volume of the *Zoonomia*. Its aim is simply to amuse, by bringing distinctly to the imagination, the beautiful and sublime operations of nature, in the order in which the author believed the progressive course of time presented them. This work, like all his productions, contains some beautiful and inimitable passages. It is not, perhaps, equal to his *Botanic Garden*. It exhibits all his excellencies, and all his faults: it shews that the vigour of his body had not outlived the vigour of his mind—that the lamp of genius burnt brightly to the last. These, together with some papers in the *Philosophical Transactions*, and the share he had (which was considerable) in the formation of the *System of Vegetables of Linnæus*, published in the name of the Botanical Society of Lichfield, are all the published works of Dr Darwin.

During his residence in Derby, he founded a Philosophical Society there, and was its able and attentive president till the time of his death. In the library belonging to that society, a biographical tribute to his memory was lately read by one of his friends: from that paper, the writer of this article, who is also a member, has extracted some interesting matter, for which he returns his acknowledgments to the author.

In perspicuity, which is one of the first excellencies of poetic, as well as prose composition, Dr Darwin has, perhaps, few equals. He is clear, even when describing the most intricate operations of nature, or the most complex works of art; and there is a lucid transparency in his style, through which we see objects in their exact figure and proportion. He delights the eye, the taste, and the fancy, by the strength, distinctness, elegance, and perfect originality of his pictures; and gratifies the ear by the rich cadence of his numbers. But the passions are generally asleep, and seldom are the nerves thrilled by his imagery, impressive and beautiful as it is. The greatest defect in Dr Darwin's poetry is want of sensation;—that sort of excellency, which, while it enables us to see distinctly the objects described, makes us feel them acting on our nerves; and, perhaps, the dazzling, and excessive polish of his lines, may have a tendency to cloy, from their richness. His picturesque descriptions are elegantly drawn. In general his poetry is addressed to the reason, for it relates to science; and to the imagination, for it is employed in fiction—but it seldom touches the heart. The outlines of his figures are drawn with astonishing strength and accuracy; but they have a hardness and a coldness. By foregoing the use of that which is addressed to the feelings rather than the eye, he has not availed himself of those fine and fleeting circumstances and associations which are beyond the reach of the pencil, but which, in poetical painting, may be made to contribute powerfully towards the general impression. In the notes to his different works, we discover the botanist, the philosopher, the chemist, and the man of an exalted and daring genius. But though he often appears to advantage, it must be confessed that, in many instances, he sacrifices too much to imagination. Had Dr Darwin written less, his fame would have been greater.

In considering the character of Dr Darwin as a physician, the first observation that occurs, is the novelty of his practice. The cause of his not following the common mode of treating various diseases, was not the effect of mere singularity, nor the idle vanity of differing from others; but the result of much thought, labour, an ingenious and acute observation, of extensive views, and an unusually accurate acquaintance with the human frame. Success almost invariably resulted from the exertions of his genius. His strength of mind and courage increased with his deviations from the usual practice; and there were many instances of his giving back his dying patient to existence and to health, by his novel mode of treatment. The whole of Dr Darwin's life was spent in meditation and study. His thoughts were uniformly, intensely, and actively, devoted to the attainment of elegant literature; to scientific researches, to the investigation of disease, and to the luminous developement of the laws of nature. (D. P. D.)

DAUBENTON, LOUIS JEAN MARIE, a celebrated French naturalist, was born at Montbar in Burgundy, on the 29th of May, 1716, and was the son of a notary in that village. He received his education in a college of the Jesuits, and from his earliest years he exhibited that sweetness o disposition, and that love of study, which formed the principal traits in his character. After having spent some time at Paris in the study of divinity, Daubenton seems to have abandoned all thoughts of the church, and to have devoted himself entirely to the medical profession. He attended with great zeal the lectures of Winslow, Hunauld, Antony Jussieu, and Baron, and took his degree of doctor of medicine at

* A very able examination of the principal doctrines in the Zoonomia, will be found in a work, entitled, *Observations on Dr Darwin's Zoonomia*, by Dr Thomas Brown, now Professor of Moral Philosophy in the University of Edinburgh. ED.

Rheims in 1741, the year in which the death of his father left him at full liberty to abandon his theological pursuits. Upon his return to his native place to follow the practice of medicine, he began his career during the prevalence of an epidemic distemper which threatened to depopulate the country, and during the progress of which he displayed great ability; but he was soon called by an unforeseen accident into a situation more congenial to his wishes.

As soon as Buffon succeeded Dufay as intendant of the Royal Garden at Paris, he formed the plan of giving a complete view of the natural history of quadrupeds. His personal knowledge of Daubenton, who resided in the same village with himself, and who had devoted a great portion of his time to the study of comparative anatomy, induced him to request his assistance in that department of his work, for which he himself was by no means qualified. Daubenton, who had already, through the influence of Buffon, been appointed keeper and demonstrator of the cabinet of natural history in the Royal Garden, felt himself honoured by the proposal, and immediately commenced those labours which have immortalized his own name, and that of his illustrious associate. He furnished all the anatomical part, and all the technical description of one hundred and eighty-two species of quadrupeds, which Buffon has given in his splendid work. In a subsequent edition, Buffon separated the labours of his coadjutor from his own; and though Daubenton was chagrined at this apparent disrespect, which has been severely reprobated by Pallas and Cuvier, yet we must admit that the unity and popular character of his work was, by this means, more completely preserved. Daubenton was elected adjunct botanist in the Academy of Sciences on the 28th March, 1744, and associate on the 1st June, 1755. From the situation of associate botanist he passed to that of associate anatomist, and he was elected a pensionary on the 21st May, 1760.

The first paper which he presented to the Academy was entitled, *Distribution methodique des coquillages, et description particuliere d'une espece de buccin, ou de limaçon terrestre,* and appeared in the Memoirs for 1743. His next papers, entitled, *De la connaissance des pierres precieuses; Memoire sur l'hippomanes;* and *Observations sur la liqueur de l'allantoide,* appeared successively in the years 1750, 1751, and 1752. In 1756, he published his *Observations sur les Musaraignes, et en particulier sur un nouvelle espece de Musaraigne qui se trouvent en France, et qui n'a pas eté remarquée par Naturalistes.* This was followed by his *Memoire sur les Chauve-souris,* in 1759, in which he describes five new species of bats. The Memoirs of the Academy for 1772, contain the history of the civet cat, which produces the musc, and exhibits some curious details respecting the organization of that quadruped; and in 1781 he published another Memoir, respecting the organs of voice in several foreign animals.

In the application of comparative anatomy to zoology, Daubenton was equally industrious; and though all his conjectures have not been well founded, yet in his Memoir which appeared in 1762, entitled, *Sur des os, et des dents remarquables par leur grandeur,* he has corrected several erroneous views which had been entertained by preceding naturalists.

Persuaded that the term *animal* was used by Buffon in a sense too extended, and that it should be restricted to those that had red blood, he proposed, in a Memoir read to the National Institute in 1797, to divide them into vertebral and invertebral animals.

The attention of Daubenton was also directed to the subject of vegetable physiology. He was the first botanist who observed that the growth of the palm tree was effected by a prolongation of the central fibres, which developed themselves in leaves; and he was also the first who recognised in the coats of the trachea a kind of brilliant and aërial vessels, which had hitherto been observed only in the structure of wood.

In the department of mineralogy, Daubenton laboured with equal zeal. His *Tableau du regne mineral;* his researches on the formation of alabaster, published in the Memoirs of the Academy for 1754; and his Memoir on the Herborization in Stones, published in the Memoirs of the Academy for 1782, give him a strong claim upon the gratitude of mineralogists. But he had also the great honour of being the master of the illustrious Hauy, whose mineralogical and crystallographical labours have extended the boundaries of science.

His researches on the occipital hole in man, which appeared in the Memoirs of the Academy for 1766, under the title of *Memoire sur les differences de la situation du grand trou occipital dans l'homme et dans les animaux;* and his essay on Indigestion, are only works which he published, as immediately connected with his profession.

Daubenton had long directed his attention to the subject of sheep, and particularly to the amelioration of the French wool. The results of his investigations were laid before the Academy in a series of Memoirs, the first of which appeared in 1768, under the title of *Memoire sur le mechanisme de la rumination et sur le temperament des betes a laine.* He afterwards considered the advantages of keeping the sheep constantly in the fold; the amelioration of beasts and wool in general; the method of curing the diseases to which they are liable; the differences between French and foreign sheep; and the purgatives which are most suitable for that animal.

In order to render useful the results of his labours, he embodied them in a work entitled, *Instruction pour les Bergers, et les proprietaires de troupeaux,* which appeared in 1782.

The other works of this industrious naturalist were, his *Dictionnaire des animaux vertebres,* published in the *Encyclopedie Methodique,* and his Lectures in the Normal School. The last of all his works was entitled *Observations sur une petrifaction du mont de Terre Noire departement de la Loire,* which was published in the first volume of the Memoirs of the National Institute for 1798. The manuscripts which he left behind him were his Lectures in the Veterinary School, in the College of France, and in the Museum.

During the terrors of the French revolution, he preserved himself, by his prudence, from the disasters which befel so many of his friends and associates.

In the year 1795, when he had reached his eightieth year, it was necessary to procure a certificate of civism, in order to preserve a situation which he had filled during 50 years. Some of his friends, afraid that this certificate would be refused, advised him to present himself as a shepherd in the Assembly of Sans Culottes, and in that character to demand his certificate. This plan was attended with complete success; and in the habiliments of a shepherd, Daubenton obtained the certificate which was necessary for holding the Directorship of the Museum of Natural History.

In the year 1799, Daubenton was elected a member of the Conservative Senate; but he did not live long to enjoy this honour. He died in December 1799, in the 84th year of his age. His Eloge was pronounced by the celebrated naturalist Lacepede, at the opening of the course of Natural History in the Museum for the year 1800, and a notice of his life and works was afterwards published by the learned and eloquent Cuvier.

Daubenton was a member of the Royal Academy of Berlin, and was elected a Fellow of the Royal Society of London, on the 9th of January 1755. (*o*)

DAUCUS, a genus of plants of the class Pentandria, and order Digynia. See BOTANY, p. 163.

DAVENTRY, or DAVENTRE, pronounced DANETRE, a market town of England, in the county of Northampton, is situated on the side and top of a hill, and encircled with hills to the south and east, on a tongue of land between the rivers Nen and Avon. Mr Pennant derives the name of the town from *Dwy-avon-tre*, the town of the two Avons; though the inhabitants, from the way in which the name is pronounced, make it of Danish origin; accordingly the badge of the town arms is the effigy of a Dane cutting down a tree. Although the town contains some good houses, yet in general the houses are meanly built, and the streets are badly paved. The church and steeple are built of soft Kingston stone, and are tolerable pieces of modern architecture. The remains of a priory, founded in 1090, are still to be seen. What now remains is supposed to have been the refectory. The doors and windows are in the pointed Gothic, and there is a large flight of steps leading to the apartments. The priory was suppressed by Cardinal Wolsey, and the conventual was made the parochial church, which was taken down some years ago, where the new one was erected.

A grammar-school was founded in this town in 1576. Five boys are educated by a legacy of Lord Avon, formerly Bishop of Durham, and other twelve are supported at school at the expence of the corporation.

At the distance of nearly half a mile to the south of Daventry stands *Borough Hill*, or *Dane's Hill*, as it is commonly called, celebrated for the large encampment which occupies the greater part of its summit. It is like that of Worle Berry in Somersetshire, and in shape resembles the human foot, being about a mile long, and about a quarter of a mile at its greatest breadth; and contains about 190 acres. It is variously defended with two, three, or four valla, and an equal number of fosses. This encampment was divided by a rampart near the northern extremity of the hill. The part which it thus cut off from the large fortification, contained about 12 acres, and is nearly of a circular form. At the north-east end of this is a moat, which was the prætorium. On the south-east side of the hill, at the distance of 300 yards from the preceding encampment, there is a smaller one, occupying about an acre of ground, and encircled by a single fosse and vallum. It has entrances on the east and west sides, and is of an oblong form. At the foot of Borough Hill, on the south, is a space of six acres, called Burnt Walls, where the remains of walls and arched vaults have been discovered; and in the adjacent wood are traces of a fortification, which has been called John of Gaunt's Castle. Pennant thinks that the encampment is the work of the Britons, while other antiquarians consider Borough Hill as the site of the Roman station.

Daventry has a large weekly market, and four annual fairs, held on June 6, August 3, October 2, and October 27, which are famous for the sale of horses. There is here a race course about two miles long; and in the town there is a considerable manufactory of whips.

The following is an abstract of the population return for 1811, for the parish of Daventry.

Number of inhabited houses,	534
Families that occupy them,	628
Do. employed in agriculture,	143
Families employed in trade and manufactures,	413
Males,	1297
Females,	1461
Total population in 1811,	2758

DAX, DACQS, or ACQS, the *Aquæ Tarbellicæ*, and the *Aquæ Augustæ* of the ancients, is an ancient town of France, and chief place of a district of the same name, in the department of Landes. It is situated on the left bank of the Adour, and is defended by a castle of no great strength, and by some fortifications which are in a bad state. Dax, however, is a military position of importance, as it covers a road by which an enemy could penetrate from Spain into France, without going by Bayonne.

In the middle of the town is a large and deep basin, always full of smoking and almost boiling water, and forming a small rivulet that runs into the Adour. There are six convents in the town. It has a weekly market, and six fairs in the year.

The mineral springs of Dax, for which it is chiefly celebrated, are situated on the west side of the town. Three of them serve for bathing, and one for drinking. The water contains a small quantity of muriate and sulphate of lime; its temperature is 56°; it is clear and tasteless, and is used for gout and rheumatism. The environs of the town are very agreeable. The adjacent country produces corn, wine, and wood; and the principal trade of the place, which is greatly facilitated by the Adour, consists in deals, rosin, tar, wheat, brandy, and wine.

Several manufactures of cloths were established in Dax in the year 1766, and the poor children were brought up to assist in the different works. They were superintended by an Englishman, who was accidentally a prisoner in the town. As soon as the proprietors had obtained all his methods, they unjustifiably dismissed him; but they found, when it was too late, that his aid was essentially necessary, and the establishment went completely to ruin. Population 4398. The position of Dax, as ascertained trigonometrically, is West Long. 1° 3′ 3″, and North Lat. 43° 42′ 19″. (*j*)
